ARTS AND SCIENCES.

JOINERY.

JOINERY, the art of uniting wood of small dimensions, for the purpose of forming those fixed details of house- or ship-building which are not connected with the solid framework of the structure: and it is usually understood that the term *joinery* is applied to this particular branch of the constructive arts, in contradistinction to the other branches, *carpentry* and *upholstery*, the former of which deals exclusively with the wooden framework of buildings, and the latter with the moveable furniture. The articles ordinarily comprised within the province of the joiner's art are doors, windows, shutters, floors, staircases, cupboards, counters, shop-fronts, &c.; and the respective descriptions of work are either plain, framed, or panelled. In order to ensure their proper execution, it is necessary that the joiner should be acquainted—1, with the nature and properties of wood; 2, with the modes of putting the wood together, alike with reference to the economical conversion of the wood, the strength of the assemblage, and the resistance to atmospheric changes; and 3, the general principles of taste, in so far as they may influence the character of the work.

1. *The woods* most commonly used for joiners' work in England are the various kinds of fir and pine imported from the north of Europe and from America; oak, either native or foreign; mahogany, rose-wood, cedar, maple, satin-wood, though perhaps the three last-named materials may be, more strictly speaking, regarded as furniture woods. Locally, poplar, chestnut, walnut, ash, beech, and some kinds of birch are used; but the practice of London joiners is almost exclusively confined to fir, oak, and mahogany.

The fir-woods used for joinery are technically known under the names of *bauk*, or of *manufactured goods*, including under the latter term *planks*, usually 11 inches wide by 3 inches thick; *deals*, 9 inches wide by 3 inches thick; and *battens*, 7 inches wide by 2½ inches thick; but it is to be observed that it is only in country districts, or where very coarse work is admissible, that bauk timber is converted to these uses. The planks, deals, and battens are, again, either of white or yellow deal, from the Baltic or Norwegian ports; or they are of white, yellow, or pitch pine, or more recently of the Vancouver's Island wood, all of which are obtained from America. The best European yellow deals come from St. Petersburg, or Gefle; the best white deals, from Archangel or Christiania; but the Stockholm, or the Riga and Memel deals, of either description, are of very nearly equal quality. Yellow deal is more fitted for doors or other panelled work than white deals, because it is less subject to warp or shrink; but the white deals are harder than the yellow ones, and therefore are more used for flooring purposes. Both white and yellow deals require, however, to be seasoned, or exposed to the air in sheltered positions, for at least from four to six years, before being employed for superior descriptions of joiner's work. The ordinary American pine deals are of a very inferior quality, whether as to grain or durability, and their use has been almost entirely abandoned by English joiners since the differential duties upon foreign timber have been reduced; but the yellow pine is still largely used, on account of its uniformly soft character, the straightness and beauty of its grain, and its immunity from knots; and for these reasons it is employed for moulded work, and for pianoforte making. The pitch-pine is a very beautiful variety of the fir woods, of a rather deeper and warmer colour than the yellow pine, and of much greater strength and durability; unfortunately, however, it is very costly, and is, therefore, only used in cases where particularly sound and durable work is required, as for ships' decks, floors, staircases in good houses, &c. But the Vancouver's Island timber seems to possess qualities of dura-

JOINERY.

bility, resistance to atmospheric changes, and colour, which place it in a very superior category to any other description of fir wood, for those joiner's purposes at least wherein it may not be absolutely necessary to work the wood against the grain. The use of this Vancouver's Island timber has not, however, been sufficiently proved by experience to warrant its application on a very large scale.

The oak used in England is either obtained in the country or is imported from Germany, or America, or Italy; and it either comes to market in the shape of bauk, log, or plank stuff, whilst in France short ends, known as *merrains*, are much used for flooring purposes. The bauk oak is used for making door- and window-cills for the best description of houses; and as those articles of joinery are exposed to alternations of moisture and dryness, it would be desirable to use for them nothing but English oak, which resists those destructive actions better than either the German or Italian oak, and infinitely better than the American oak. For the more ornamental descriptions of joiners' work wainscot logs are used, after having been sawn into plank stuff and properly seasoned. The best of these logs are obtained from the woods of the interior of Germany, and they are exported from Riga under the name of *Dutch wainscot*. This material, when properly seasoned, is not liable to warp or to shrink; it blackens with age, but is always susceptible of receiving either a varnish or a polish; its texture is by no means unfavourable for working mouldings, either with or against the grain; it is very durable, strong, and hard, but by reason of the latter property the labour upon it becomes considerably greater than the labour upon deal or pine. Wainscot has one great advantage over ordinary deal or pine—namely, that it does not require to be painted; and though the Vancouver's Island timber, or the pitch-pine, may dispense with that mode of decoration or protection, their colours and *flower* (as workmen call the variations of tint or pattern in the different parts of the wood) are certainly not so pleasing as those the wainscot. For delicate wood-carving, the yellow pine is unquestionably superior to any other wood, because it is both softer and more uniform in its texture; but wainscot is very well fitted for such purposes, and the elaborate carving of the mediæval pulpits, stalls, confessionals, &c., may be cited as affording illustrations of the success with which this wood may be applied to the higher branches of the arts. The very remarkable pulpits and confessionals of Belgium and of Northern Germany may be especially referred to on this score.

The best mahogany which is introduced into this country for joiner's work is the produce of the southern part of the island of Hayti; the mahogany from the northern part of that island is of an inferior quality, and approaches very nearly the character of the worst descriptions of Honduras wood. The logs exported from Cuba are often very beautiful, indeed almost equal to the best Hayti (or, as it is technically called, the *Spanish* mahogany); but it is not of such large dimensions as the Honduras wood, nor is it so uniform in the beauty of its flower as the Spanish. The best Honduras mahogany is very well adapted for ordinary works and for ship-building; but it is usually of a straight grain, without any varieties of tint, and is not therefore fitted for such works as hand-rails, doors, counter-tops, &c., where variety of colour is required. The commoner descriptions of Honduras wood are only used for carriage-builders' purposes, for interiors of drawers, or even for ship-building; and for all these purposes their low price, their great strength and durability, and their singular freedom from any tendency to warp or crack, make them very desirable. Mahogany of any description is worked evenly, but with difficulty, and on those accounts the labour upon it is expensive; for ornamental carving it is admirably adapted,

but as it turns almost black with age, the original effect of the carving may be lost. This wood is susceptible of both oil and spirit varnish or polish.

2. The modes of putting work together must of course depend upon the particular object it may be desired to accomplish; and perhaps the most convenient mode of describing them would be to take illustrations from some of the more generally known articles of joiner's work.

In floors it is usual, especially in countries where fir or any of its varieties is commonly employed, to execute them with boards cut as nearly as possible to an even thickness. The upper surface of the boards is then planed, the edges shot, and a narrow border is worked on the under side, exactly parallel with the upper surface, leaving an intermediate space to be adzed off when the boards are to be fixed. In the best floors, narrow boards only should be used, of between $4\frac{3}{4}$ and $6\frac{3}{4}$ inches, in finished width; or in fact, they should be formed out of deals, with a cut down the middle, or out of battens; the joints should be *straight*, *grooved* and *feather-tongued* (or with a groove worked in each board, and filled in with a thin slip of wood, or of iron, as in sketch ) , and the heading-joints should be *splayed*

thus, ; sometimes, instead of grooving and tonguing the

boards, they are merely *edge-nailed*. Where the boards come near hearths, a glued and mitred border should be introduced, even when the floor boards are not intended to be habitually exposed. In the floors of bed-rooms, or of apartments wherein carpets or matting are likely to be permanently used, the boards may, without inconvenience,

be 9 inches in width; and in warehouse floors they may be made 12 inches wide. Upon the continent, and in some cases in our own country, however, where wainscot floors are used, the narrow boards are laid in what is called *herring-bone fashion*, as in sketch; but in such cases the floors are always left uncovered, and they are waxed, or dull polished. The thickness of floor boards would naturally depend on the wear they

are likely to be exposed to, and upon the distance apart of their points of support; as a general rule it varies between $1\frac{1}{2}$ and 1 inch.

In staircases of wood, the usual practice is to frame the *treads*, or the horizontal parts of the steps, and the *risers*, or the vertical parts, into *wall* and *outside strings*; the former of which is a stout piece of wood nailed against the walls of the *well-hole* of the stairs, and the latter, an equally stout piece of wood starting from a *curtail step* at the bottom of the stairs, and either framing into a solid post, or *newel*, in what are called *dog-legged staircases*, or carried round by means of curved ramps to the trimmer of the upper landing in *geometrical staircases*. The *risers* are usually grooved into the under side of the treads, and the latter project so as to form a *nosings*, whilst the joint is hidden by a small hollow, nailed to the underside of the tread; small blocks are glued to the inside of the joint, and, if the width of the staircase be considerable, the frame-work is strengthened by means of brackets let into the wall, and by blocks. In some staircases the outside string is cut, and the nosings are returned at the

ends of the steps; in others, the string projects above the ends of the steps. The ballusters in the former case are let into the steps; in the latter, they are let into the string-board; but under all circumstances the ballusters are fixed at top to a hand-rail, usually worked out of solid mahogany, the various parts of which are known by the names of *straight*, *ramp*, *twist*, *wreath*, *curtail*, *newel*, *scroll*, &c.

In framed work, as all panelled, or indeed all compound pieces of joinery are called, the various parts are assembled in either one or the other of the following manners, at the external angles. The

large surfaces are either put together with straight joints, which are *keyed* at the back, that is, bound by means of a longitudinal tie; or are *clamped*, that is, let into a piece running in the same plane with the vertical boards, but in a horizontal direction; or are panelled, that is, made with stout *styles* and *rails* filled in with straight jointed boards, so that the styles and rails form raised frames above the surface of the panel face. When wall linings are executed, they are frequently made with what are called rebated and bead flush-

joints  for the purpose of disguising the shrinkage of

the various boards, and they finish against a beaded capping; but it is in the putting together of doors, cupboard-fronts, and shutters, that the greatest varieties of framing are admitted. Thus doors are either *plain clamped*, or they are *plain clamped and ledged* doors, when they are made with straight joint boards, clamped at the top and bottom, or when they have in addition, ledges to receive the hinges or to stiffen the work; sometimes clamped and ledged doors are executed with joints beaded on one or both sides. Panelled doors have four or

six panels, as the case may be, and they are either made with the filling in parts flush with one side of the work, or sunk below the level of the framing on both sides; so that the doors are said to be either flush one or both sides, or panelled one or both sides. Again, the panels may be either *bead flush*, or *bead butt* (the former, when the beads mitre and return at the extremity of the panels, so as to make a regular frame round it; and the latter when the beads butt against the top and bottom rails); or they may be *square both sides*, or *moulded one side and square*, or *moulded both sides*, according to the mode of ornamenting the panels. Sometimes also the panels are *raised*; or they may even project beyond the face of the framing, and then become *bolection* panels. All these doors are fixed either in solid frames, or upon framed grounds and jamb linings, with the necessary architrave mouldings.

Windows are either made with fixed sashes in solid frames, and with two or more panes of glass carried by sash-bars. If the windows should be made to open, by rising or falling vertically, they are called single or double hung sashes, as the case may be; if they open on hinges, they are called *pivot sashes*, when they simply revolve on horizontal or vertical pivots; or *casement sashes*, in one or two leaves, when they open on vertical hinges fixed to the sides of the frames. The frames themselves are either *solid* for pivot or casement sashes, or they are *boxed frames*, for single or double hung sashes; and the latter are made with outside beads, parting beads, parting slips, axle pulleys, lines and counter weights as may be required. Shutters are either made to slide into boxes placed in the window backs, and placed under the level of the window-cills, or they are made to close into boxes, either splayed or square, from the frames; and they may be in one or more leaves as may be required, in order to avoid needlessly projecting into the room. External shutters and sunblinds are, in fact, modifications of internal shutters, and are sufficiently well known to allow of their being passed over without any detailed description. With regard to cupboards, counters, shop fronts, dressers, drawers, and the other countless details of house finishing which enter into the province of the joiner, it may also suffice to say, that the principles of their framing are so closely allied to those involved in the execution of doors and sashes, wall linings, &c., above described, that they may be summarily disposed of, by saying that the general conditions all such works should fulfil, should be that the wood of which they are made should not be exposed to shrink, and that the various parts which are intended to move, should be able to do so freely and easily. The various works in question may be executed in solid wood, or in wood *veneered*, or covered by a thin sheet of some more valuable description of wood glued to the exposed face of the commoner one serving as the sub-structure; and in such cases as the execution of columns, rounded corners, circular niches, &c., narrow pieces of wood are put together with glue, and blocked or keyed at the back.

The mouldings most commonly used in joiner's work are as follows:

Of these, the No. 1, is simply a *rounded end*; No. 2, is known as a *quirked bead*; No. 3, as a *double quirk bead*; No. 4, is a *double bead and quirk*; No. 5, is a *double fillet*; No. 6, is a *torus bead*; No. 7, is an *ogee*, and No. 8, a *reversed ogee*; No. 9 is a *hollow and half round*; and No. 10 is an *ovolo and bead*. The mouldings 1 and 3, are used for projecting pieces of wood, or for projecting angles; Nos. 2, 4, 5, 6, are used for horizontal joints; Nos. 7, 8, 9, and 10, are used for cappings or for bead-moulds.

Now the general use of panelling in framed work, which is so very conspicuous throughout northern Europe at least, has been the result of practical considerations of economy of conversion, and strength of assemblage of the wood, as well as to its resistance to atmospheric influences upon its dimensions. Thus, in a wall lining of any considerable area, the panel frames are formed with rather thicker material

than might theoretically have been required, but the panels themselves are made as much thinner in proportion; and, as their surface is greater than that of the styles and rails of the framing, an economy of material is obtained. Moreover, as the direction of the grain of the wood in the various parts of the framing differs in the cases of the rails

and panels from that of the styles, the tendency of the respective parts to shrink or to warp is to some extent counteracted. Again, the heading joints of the styles and rails are made with what are called *mortice and tenon joints*, or those in which a hole of a rectangular form is cut in either the styles or rails, and into it is closely fitted a projecting tongue left on the other piece to be assembled, which is subsequently fixed by the use of glue, wedges, or pins. Before, however, the framing in this supposed case is wedged up, the panel is introduced, and fitted into grooves left in both styles and rails; and after the whole has been wedged up, a moulding is nailed to them, all round the panel, so as to allow the latter to shrink without exposing the joint. It is a similar motive to the latter which leads to the use of what are called

matched and beaded linings ; for the shrinkage in

the width of the planks is in them rendered less apparent by the introduction of the double quirked bead, formed by the bead on the edge of one board and the rebated joint on the other. These remarks apply also to doors; but the introduction of panels in them, and in window shutters, &c., has the additional advantage of rendering the particular articles to which they are applied actually lighter; whilst at the same time they tend to destroy the unpleasant effect of large, unmeaning, plane surfaces. The introduction of panelled work into strings of staircases seems to be very questionable, either in point of taste or of construction; and that joiner's work which is manifestly intended to resist violent actions or great weights, should be, and should look as though it were, of the most solid and substantial description.

In the preparation of tanks, cisterns, vats, and other vessels intended to contain water, great attention must be paid to the manner of making the horizontal joints, which are usually formed with grooved and feather tongues, set with white lead instead of glue, and to the lateral stiffness of the sides. The principles which regulate the thickness of such vessels belong to the science of HYDRODYNAMICS.

It is essential to observe that the durability of joiner's work depends upon its being removed from sources of damp, or from confined air, especially when the latter is both warm and damp. The planks which contain any sap-wood are certain to decay with rapidity in such situations; spruce fir decays more rapidly than pine, or ordinary deal; all soft woods decay more rapidly than oak; and of oaks, those which are the hardest last the longest in damp positions; mahogany resists change of hygrometric state better than fir-woods, but not equally well with oak. Joiner's work which has been veneered is not fit to be exposed to alternations of wet and dryness; and indeed any glued work will certainly fall to pieces if kept for any time in a damp state, whilst extreme heat is equally prejudicial to it. Perhaps mahogany resists strong light and heat better than any other wood, and it is on this account much used for making shop-fronts, or for external joinery. It is also used for hand-rails of staircases in preference to all other varieties of wood, because of its markedly small tendency to break into splinters, and this fact may also account to a great extent for its use for tables or counter-tops.

3. It is rather curious that whenever the taste or the fashion of an age has brought the art of wood-carving conspicuously into notice, the architecture of the period has begun to degenerate into a florid and rather over-ornamented style; as for instance, about the latter end of the middle ages, the taste of the wood carvers of Westphalia seems in Germany to have led to the elaborate complicated style observable in the Gothic structures of the end of the 15th and beginning of the 16th centuries; whilst the elaborate wood sculptures of the Flemish churches of the 17th century were contemporary with the introduction of a still more equivocal taste. How far the art of wood-carving has acted upon, or been reacted upon, by the taste of the age, it would be hard to say; but there certainly would appear to exist some tendency on the part of those who work in a material so easily made to yield to the artist's fancy as wood certainly is, to indulge in the display of their imagination, and of their own manual dexterity; and this tendency has on some occasions proved to be so overpowering that it becomes almost necessary to recall the attention of the workers in wood to the necessity for their studying the abstract laws of beauty as applied to art structures. Even in the case of common joiners, there seems to be somewhat of the tendency to transfer to other arts the modes of thought suggested by the practice of their own; and we consequently find that the architecture known as "carpenter's architecture" is marked by the panelling of all plain surfaces, and an unaccountable introduction of beads, toruses, and ogees. The laws of taste applicable to one art, in fact, are rarely applicable to others; and those applicable to joinery are of so narrow and so limited a character as to lead to very ridiculous results if extended beyond their proper sphere.

It seems, indeed, that beyond the mere questions connected with the colour and grain of the woods employed (so far as they influence the style of decoration), the principal laws of taste in the use of joiner's work are that, 1st, no ornaments should be introduced, or no mode of assembling the framing be adopted, which should appear to weaken the strength of the work, or to bring efforts upon it in directions wherein the wood would be the most likely to yield; 2nd, that no attempts should be made to represent in joiner's work methods of con-

struction exclusively applicable to other materials; 3rd, that the harmonic proportions of panels, or other framed joiner's work, be rigorously observed. All questions of detail must of course be made subservient to the general design; and, in the latter, care should be taken not to bring the works of one set of artisans too strongly into prominence.

JOINT. In constructive operations the word *joint* is used to express the means adopted to ensure a greater length in any part of the work than can be obtained by the use of the natural materials, or to form large masses of work; or to enable one part of the work to turn upon another, in the manner of a door, casement, &c. The different kinds of joints of the first description assume names dependent upon their forms, positions, and the materials in which they are executed; and the joints of the second description assume names dependent upon the manner and extent of opening they are intended to secure.

Thus, in masonry and brick-work, the sides, or vertical faces of the materials within the face of the walls, are called *joints*, in contradistinction to the horizontal faces or *beds*; and they are called either *heading* or *stretching-joints*, as they may be laid with their shorter or longer dimensions in the same direction as the face. They may be perpendicular to the face or dovetailed, as in the courses of the Eddystone Lighthouse; and in arches they are made normally to the curve of the intrados; in ornamental work they are sometimes *rusticated*, or made either with a species of sunk rebate or with splays on the edges, thus:

and they are either (in ashlar masonry) *cramped* on the top, *dowelled*, or made with a *joggle* thus:  this form of joint is used for landings of staircases. When straight architraves are carried over wide openings, it is customary to form in them what are called *concealed arch-joints*; a very vicious style of construction, it may be added.

The various descriptions of joints used in timber-work differ from those of masonry and brick-work, in this respect: that they are expressly made for the purpose of lengthening the several pieces of wood, rather than of enabling them to form parts of a structure, whose stability should consist in the reaction of the laws of gravity, on the materials employed, upon those materials themselves, as in the case of stone and brick-structures. The joints of wood work then are:—No. 1, the *lap-joint*, in which one piece of timber is cut out so as to allow the other to fit over it and to be fastened simply by nailing. No. 2, the *dove-tailed lap-joint*, in which the faces of the laps are cut

with an inclination from one another, so as to offer a resistance to the lateral displacement of the timber; and this object is more effectually attained by the *scarf-joint*, No. 3, especially when it is (as in the sketch) keyed and wedged. In certain positions, as in tie-beams of long span, the scarf-joints, instead of being made horizontally, are made vertically; but, in all such works it is customary to stiffen them by means of bolts and of plates of wrought-iron, on either side of the scarf. In joiner's work, *lap-joints*, *grooved* and *tongued-joints*, *tenon-joints* and *splayed-headings* are used, for a description of which see JOINERY.

In metal works, joints are sometimes lapped, dovetailed, and scarfed, as in carpentry; but they are also either *welded*, *brazed*, or *soldered*, according to the nature of the metal and of the purposes intended to be effected. *Welding* consists simply in bringing the ends of the metal to such a heat, as to allow the percussion exercised upon them, when in that state, to effect a complete homogeneous junction of the respective ends—to make the lengthened bar, in fact, precisely analogous in its powers of resistance to longitudinal strains to those of the original bars. *Brazed joints* are those made when edges of iron, copper, brass, &c., are run together by means of an alloy consisting of brass and zinc, with occasionally small proportions of tin and silver. *SOLDERED JOINTS* are very nearly the same as brazed joints, or they are those made when surfaces of metal are united by means of a more easily fusible material, which is run between the said surfaces, and binds them together by chemical and cohesive force; and thus according as the metal surfaces are similar or different, it becomes necessary to vary the nature of the solder to be used. The most important observation to be made with respect to the execution of either of these fused joints is, that it is essential to keep the faces of contact perfectly bright, and free from any kind of dirt or extraneous bodies. In metal work, rivet joints are also used.

The hinge joints used in joiner's or smith's work, are of an almost endless variety, but in common practice they may be said to be comprised under the following principal varieties. The *butt joints* are those in which the hinge is made to bear a rounded edge, for the purpose of carrying on the line of a bead worked on the edge of the frame, designedly to hide the mode of hanging; sometimes, however, the butts are made to project when the door, casement, flap, &c., may be required to fold back over a projection. A description of hinge joint, called a *back flap*, is sometimes used in common work, for the same purpose as butt hinges; and when the development of the door is very considerable, the joint is made with what are called *pulpit hinges*. *Rule joints* are used when the doors or windows require to open back to great distances; that is to say, when the centres of

motion are situated at distant points from the plane of the closed door or window; *quadrant joints* are sometimes used for this purpose, but they are identical in principle with rule joints. Pivot joints, and swing centres are those used when the doors and windows are made to revolve on fixed points, placed either vertically or horizontally, either within or beyond the plane of the closed work. The objects to be attained in any of these descriptions of hinge joints are, that the various articles to be moved should be able to do so easily, and without friction or noise; and that they should shut close, so as to prevent air or dust from passing through.

In the enclosures of railway sheds or in waiting-rooms of railway stations, a description of joint, known as a *sliding joint*, is used, in which the doors are carried upon rollers that run upon a rail, above or below the door; and in modern shops the external shutters are made with what are called *revolving joints*, or they are made to wind round a horizontal or vertical bar, upon a species of tambour frame. It may also be desirable here to add, that in pipe laying, the joints are either made with a *spigot and faucet*, in which the end of one pipe fits into a socket cast on the end of the other, and is rendered steam-water- or gas-tight, by the yarn, whitelead, or melted lead run into the interval; or they are made with *flanges* or broad faces made to bear closely against one another, either with a turned face, or by the interposition of some elastic substances.

JOINT-STOCK COMPANIES. These Companies are distinguished from other Corporations by being associated, not for any public or administrative purpose merely, but for carrying on a trade or business with a view to individual profit. They possess other peculiarities equally deserving of notice.

This system of association, which has received such gigantic development in modern times, is by no means of recent origin. Institutions founded on the same principle as the trading guilds of the middle ages seem to have existed among the Saxons; and soon after the conquest we find companies of different trades established in the various seaports and other towns of importance in the kingdom. These fraternities generally became in course of time chartered corporations; each possessing the exclusive privilege of following the particular occupation which it professed to protect. After the Reformation they mostly became merged in the municipal corporations, the franchises of which could in many cases be enjoyed by those only who were *free* of one of the companies into which the community was divided. In this position they remained until the Municipal Corporation Reform Act. Besides these guilds, or companies, other trading associations sprung up from time to time. The general company of Germans, called also the Merchants of the Hanse, dates from 1220, and became in the 15th century the Company of the Steelyard. In 1505, the "Merchant Adventurers of England, for trading in woollen cloths to the Netherlands," obtained a charter of incorporation, prohibiting the Hanse merchants from interfering with them, and the Steelyard Company seems thereafter to have gradually declined. In 1553, was established the company of "Merchant Adventurers for the discovery of lands, countries, isles, &c., not before known by the English," which resulted in the establishment of a trade with Russia. The Turkey Company, the African Company, the Eastland Company, the East India Company, were all chartered monopolies; but the Hudson's Bay Company alone remains on this ancient footing.

Soon after the Revolution, the principle of association began to be applied to a variety of purposes besides those of foreign adventure. Numerous projects were started, the execution of which could not be compassed by private means, but which it was thought might be attained by raising capital on the joint-stock principle. Hence arose, in the early part of the 18th century, the speculative mania, remembered in connection with the famous South Sea Company; of which we have seen counterparts more than once in our own times. To meet the evils occasioned by this novel development of the associative tendency, the "Bubble Act" (6 Geo. I. c. 18), was passed, declaring all companies which presumed to act as corporate bodies, and to pretend to raise transferable stock, public nuisances, and the promoters of them punishable accordingly. This statute was directed not so much against the offence of acting as a corporation without authority, as with a view to prevent the frauds of unprincipled adventurers, who proposed schemes merely as baits to extract money out of the pockets of the thoughtless. Such an object, however, is not to be effected by mere legislation. The gambling in stocks and shares which seems to be periodically revived among us, and which, in 1719, produced the "Bubble Act," came to an end during the crash following the wild speculation which led to the statute; but the Act, nevertheless, had some effect in restraining for the future projects of a similar character to those against which its provisions were directed.

During the last century a large number of useful public undertakings, such as the making of canals, bridges, harbours, docks, and the like, have been carried into effect by companies formed on the joint-stock principle, and incorporated by Acts of Parliament; and more recently our gigantic system of intercommunication by railway has been obtained in a similar way. In these undertakings, the assistance of the legislature was necessary, not so much to give a corporate existence to an association of capitalists, as to enable the company to carry out its project by the compulsory purchase of property, and to make by-laws binding on the public for protecting the rights of the

corporation. These companies, like the old trading associations, partake of the advantages derived from incorporation; advantages in which mere associations of individuals joined together to promote such common objects cannot possibly participate. A mere assemblage of adventurers cannot, for instance, by any agreement among themselves sue or be sued in the name of any one of their body, or of any officer they may select for the purpose; they are liable, on the contrary, to the same laws as ordinary partnerships, and each individual is responsible to his last shilling for the acts and omissions, the contracts and debts, of the body generally. To facilitate the operations of such associations, various statutes have been passed; but owing to the fluctuation in opinion regarding the true policy to be pursued, the legislation relating to them has not been altogether consistent.

The original mode of forming a joint-stock company was by means of a deed of settlement, which constituted trustees of the partnership property, directors of its affairs, auditors of its accounts, and other officers, defined the number of shares into which the capital was divided, and the form and mode of transferring them, and laid down rules for periodical meetings of the shareholders. In the absence of legislative interference, the rights and liabilities of the members of such bodies, in relation to the public, were the same as those of other members of ordinary partnerships; their rights and liabilities *inter se* depended on the provisions of the deed of settlement. The difficulties which were soon found to arise, in carrying on the business of such undertakings, induced the earlier joint-stock companies to obtain private Acts of Parliament, which usually enabled the company to sue and be sued in the name of the secretary or some public officer appointed for the purpose, and almost invariably concluded with a proviso that nothing therein should tend to *incorporate* the partnership; for one effect of incorporation would have been to destroy the individual responsibility of the members for the acts of the association, which the legislature, until quite recently, most carefully retained. As joint-stock companies, however, increased in number and in usefulness, the cost and trouble necessary to obtain a private Act of Parliament were felt to be extremely burdensome; and the attention of parliament being called to the subject, it was thought expedient by the legislature to empower the crown to grant to joint-stock companies such powers as were likely to be most useful to them, without, however, conferring all the incidents of a corporation. The first attempt at legislation in this direction was the statute 6 Geo. IV. c. 91, which enabled the crown, in any charter of incorporation thereafter to be granted, to provide that the members should be individually liable for the debts and engagements of the corporation. This act proving inoperative, another mode of proceeding was tried by 4 & 5 Wm. IV. c. 94, which enabled the crown to grant to joint-stock companies the privilege of suing and being sued in the name of any of their officers. This act was soon repealed, and another attempt made in the same direction by 7 Wm. IV. and 1 Vict. c. 73. At length the 7 & 8 Vict. c. 110 was passed, for the registration, incorporation, and regulation of all future joint-stock companies not requiring nor obtaining a charter or act of parliament. This statute introduced a system of public registration, by which the company became *incorporated*, for the purpose of carrying on the business for which it was formed, according to the provisions of its deed of settlement; but every shareholder remained liable individually for the debts and contracts of the company, and might be proceeded against as though he were not a member of the corporation. Banking companies were excepted from this statute, the 7 & 8 Vict. c. 113 being passed for their special regulation.

A great many joint-stock companies were formed, and by registration obtained the corporate privileges, which they were now enabled to do; but before long the affairs of several became involved, and the difficulties which then presented themselves in attempting to adjust the rights and liabilities of the shareholders led to the Winding-up Acts, 11 & 12 Vict. c. 45, and 12 & 13 Vict. c. 108, which for several years exercised the acumen of the judges of the Court of Chancery, in a series of hopeless attempts to interpret and follow out their provisions. The effect of the litigation carried on under these Acts was to throw a very strong light upon the principles of legislation applicable to joint-stock companies; and the knowledge thus purchased at an enormous expense led to the repeal of the Registration and Winding-up Acts, and to a total remodelling of the law regarding these associations. This has been effected by the statute 19 & 20 Vict. c. 47, which provides for the registration, under its own provisions, of all companies previously registered under the former statute. The Act itself has been amended by 20 & 21 Vict. c. 14.

The principle of limited liability, or the restriction of the responsibility of each member to the amount of the capital subscribed by him, which had long been conceded to companies incorporated by Act of Parliament, without baneful effects to the commonwealth, has been at length extended to all joint-stock companies coming within the operation of these Acts which choose to adopt their provisions, on the sole condition of obtaining registration and conforming to a few simple rules, whereby the personality of the company is defined. From its operation are excepted all companies established by Act of Parliament, royal charter, or letters patent, all banking or insurance companies, and associations engaged in mining in the Stannaries, where companies with a limited liability may be formed conformably to certain local customs, which are generally known as the *Cost-Book System*.

There now exist, therefore, four classes of joint-stock companies.

1. Trading companies incorporated by special Acts of Parliament. This class includes railway, dock, harbour, and canal companies, many insurance companies, and a vast number of other bodies engaged in every species of profitable employment. Formerly each company thus incorporated was governed by the peculiar provisions of the Act which it obtained; but in order to introduce uniformity, a general Act, applying to all future companies, was passed under the title of 'The Companies' Clauses Consolidation Act,' 8 & 9 Vict. c. 16. This statute contains a complete code for the regulations of the proceedings, the transfer of the shares, and the general management of companies incorporated by Act of Parliament. 'The Lands' Clauses Consolidation Act,' 1845, was passed at the same time, consolidating all those provisions which it had previously been necessary to insert in the special Act of any company, which required powers of acquiring land compulsorily for the purposes of the undertaking.

The peculiar character of railway undertakings rendered necessary 'The Railways' Clauses Consolidation Act,' 1845, which lays down regulations as to the construction of railway works, the amount and mode of enforcing the payment of tolls and fares, and the making of by-laws for the conduct of their business, which are binding upon all persons whatsoever.

2. A second class of joint-stock companies consists of the very few established under the statute 1 Vict. c. 73, or the preceding Act, 6 Geo. IV. c. 91, which have been already referred to.

3. Banking companies formed since 1844 form a distinct class. They were until recently regulated by the statute 7 & 8 Vict. c. 113, but must now be registered under 'The Joint-Stock Banking Companies' Act,' 1857, which preserves the individual liability of the partners, and contains provisions for the company being wound up. Banking companies constituted previous to 1844 may avail themselves of the advantages of the statute, by being registered under its provisions.

4. The last class of trading corporations are the registered joint-stock companies, regulated by the Joint-Stock Companies' Acts, 1856 and 1857, under which seven or more persons may, by subscribing a memorandum of association, and otherwise complying with the requisitions of the statute in respect of registration, form themselves into an incorporated company, with or without limited liability.

This registration is obtained by delivering to the registrar of joint-stock companies a memorandum of association, stating certain particulars in a prescribed form. Upon registration being effected, the subscribers, together with such persons as from time to time are admitted to be shareholders in the company, become a body corporate, having a perpetual succession and a common seal, and power to hold lands to a certain extent, and with consent of the Board of Trade to any extent whatever.

The company may hold itself forth to the public as one of which the members are liable with or without limit, according as the founders of it choose to adopt the principle of limited liability or not. Where the liability of the shareholders is limited by the memorandum of association, the word "*limited*" must be the last in the registered title of the company, and must be inseparably attached to its name.

The statute requires that a register of shareholders shall be kept, and that this list be annually revised, and a copy furnished to the registrar of joint-stock companies. This copy is open to public inspection, so that all the particulars of importance respecting the company can be at any time ascertained by persons dealing with it.

The affairs of a registered company are also liable to examination by the Board of Trade; while the statutes contain a complete code of regulations for winding up a company unable to meet its engagements, or which it is thought desirable to wind up for other reasons. Directors who declare a dividend when the company is insolvent are jointly and severally liable, to the extent of the dividend, for all the debts of the company; and every person concurring or carrying on the business of the company when the number of the partners is less than seven, is severally liable for its debts.

This species of corporation may be dissolved by being wound up, either voluntarily or compulsorily. A voluntary winding up may take place: 1, whenever the period, if any, fixed for the duration of the company expires, or the event, if any, occurs upon which it is to be dissolved; 2, whenever the company has passed a special resolution requiring its winding up.

A company may be wound up compulsorily: 1, by virtue of a special resolution to that effect; 2, whenever it does not commence business within a year of its incorporation, or suspends business for a year; 3, whenever the shareholders are less than seven in number; 4, whenever the company is unable to pay its debts; or, 5, whenever three-fourths of the capital have been lost or become unavailable.

A company is to be deemed unable to pay its debts: 1, whenever a creditor for 50*l.* has served a demand of payment, and the company has for three weeks neglected to pay the claim, or to secure or compound for it to the satisfaction of the creditor; and, 2, whenever an execution is returned unsatisfied, in whole or in part.

The proceedings take place in the case of companies whose liability is unlimited, in the Court of Chancery; in the case of companies with limited liability, in the Court of Bankruptcy. (Blackstone's 'Commentaries,' Mr. Kerr's edition, vol. i., p. 526.)

JOINT TENANCY signifies joint ownership of two or more persons in land, or other property, as goods and chattels. It differs from Tenancy in Common [COMMON, TENANCY IN] and Coparcenership [PARCENERS] in the following essentials: joint tenants are severally seised or possessed of the undivided whole of the land or other property in which they have a joint interest, and also of their several shares, which shares are always equal shares, inasmuch as joint tenants take by purchase only, and by a joint title: the estate or interest must be limited to the several persons by the same deed or instrument, and such estate or interest must vest in them at the same time, except (according to the more common opinion) the estate be limited to take effect under the Statute of Uses or by devise, in which cases the contemporaneous vesting of the several parts is not necessary: the whole estate or property will go to the survivors and survivor of the joint tenants, if the jointure continue until such survivorship; which is the important characteristic of a joint tenancy. It is a consequence of the mode in which joint tenants are legally considered to be seised or possessed, and of the right to the whole which accrues to the survivors and survivor, if no separation of the joint tenancy has been made before such survivorship takes place—that they cannot grant, or bargain and sell, or surrender or devise to each other; they cannot exchange with each other, nor can one make a feoffment to another. But any joint tenant may transfer his interest to any one of his companions by release, or rather he can by such instrument put an end to his interest; and any joint tenant may convey his share to a stranger by grant; or he may compel his companions to make a partition, by statute. Every person to whom the interest of a joint tenant is transferred becomes, as to such share, a tenant in common with the remaining joint tenants.

A joint tenant cannot dispose of either the whole or the part of the property in which he is jointly interested consistently with the proper notion of a joint tenancy, by a will made during the continuance of the joint tenancy, even though he should happen to be the survivor; because until he has survived he has nothing to dispose of by will. But by severing the joint tenancy he acquires the power of disposing of his share by will. By the Wills act (1 Vict., c. 26), a person may by a will, made according to the provisions of that act, dispose of all real and personal estate to which he shall have a legal or equitable title at the time of his death, and which, if not disposed of by will, would go to his heir, or the heir of his ancestor, or to his personal representatives. But this act gives no power of disposal over the unsevered interest of a joint tenant.

As to the written instruments and words by which a joint tenancy may be created, and the various rights and remedies which belong to a joint tenant, it is not necessary to dwell at any length here. The discussion of them belongs to special treatises on law. As an example of words which would create a joint tenancy, we may take the case of a feoffment to two or more persons and their heirs, which would make the feoffees joint tenants in fee simple, so that the survivors would always succeed, and the last survivor would take the whole in fee, unless any one of the joint tenants had in his lifetime conveyed his share. And generally, when there is a gift of real or personal estate to several persons, and nothing more is said, these words make them joint tenants, even in the case of pecuniary legacies and residuary bequests. To create a tenancy in common, it is not necessary, either in a deed or will, to declare that the parties to whom the gift or devise is made shall take it as tenants in common, and not as joint tenants. Any words which undoubtedly convey this meaning are sufficient for the purpose; but less exact or definite words are required for this purpose in a will than in a deed. Where an estate is given to two persons and the heirs of their bodies, if the two persons are such as cannot have common heirs of their bodies (as two men or two women, or a man and a woman who cannot legally intermarry), then such persons are joint tenants for life, but have separate inheritances, or are tenants in common in remainder in tail. But if the gift be to a man and his wife and the heirs of their bodies, or to a man and woman who may marry and the heirs of their bodies, the parties are joint tenants of the inheritance; and if they be husband and wife they take by entirety. The tenancy by entirety is a consequence of the legal unity of husband and wife. Such tenancy exists when real estate is limited by deed or will to husband and wife jointly during their marriage for an estate of inheritance or freehold: the husband and wife possess the lands entirely as one individual; on the death of either of them they go to the survivor, and there is no power of alienation or forfeiture of either alone which can prejudice the right of the other.

Partners in trade are joint tenants of the partnership stock which is of a moveable kind, but on the death of a partner his personal representatives become tenants in common in equity, with the surviving partners; and it was at one time considered that they acquired a legal tenancy in common, with the survivor. In equity there is no survivorship in lands which partners have held for the purposes of trade.

If money is jointly advanced by two or more persons on a mortgage security, there is in equity no benefit of survivorship among them.

A joint tenant, like a tenant in common, cannot maintain an action of trover against his companion for goods which are in his companion's possession; for according to the English doctrine of possession, possession by one joint tenant, tenant in common, or

parcener, is generally the possession of all. The doctrine of possession by joint tenants, tenants in common, and parceners, is materially altered as to lands and rents by 3 & 4 Will. IV., c. 27, sec. 12, and in another case by sec. 13.

JOINTURE. This legal term was originally used to denote the interest of joint tenants, which interest was called an estate *in jointure*. Before the statute of 27 Hen. VIII., c. 10 (of Uses), lands conveyed to uses were not subject to dower; and as such conveyances were frequent, it became usual to stipulate, upon a treaty for a marriage, that the intended husband should convey an adequate portion of his lands to the use of himself and wife *in jointure*, that is, as joint tenants for their lives, whereby a provision would be secured to the wife, if she survived, commensurate in point of duration with the dower which the common law would have given her, if the system of uses had remained unknown. When the Statute of Uses was passed for transferring the legal estate to the *cestui que use*, it was considered unreasonable that wives should by means of the destruction of uses be entitled to claim dower in their husbands' lands, and should at the same time enjoy a provision made for them in consideration that they were not so entitled. The sixth section of this statute therefore provided that women having provisions in the nature of jointures should not be entitled to claim dower of the residue of their husbands' lands. [DOWER.]

An estate limited to a woman must, in order to be deemed a good jointure and a bar to dower under this statute, commence and take effect in possession or in profit immediately on the death of the husband. It must also be for the life of the wife, or for some greater estate. It must be in satisfaction of the whole dower, and not of a part only. It must be made before the marriage; for by the ninth section, if the jointure be made during the marriage, the wife is at liberty after the death of her husband to refuse the jointure and demand her dower. If however the widow once accept such jointure, she is perpetually bound, even though the estate in jointure created during the marriage be made subject to a condition, and is in that respect less beneficial than dower.

A woman, though under age at the time of her marriage, is bound by an antenuptial jointure, inasmuch as the bar of dower arising out of the limitation of a jointure is not a matter of contract (by which minors are not bound), but proceeds upon the ground of the substitution of a new provision made by the husband, or on his behalf, under the authority of an act of parliament. It was formerly considered that the estate must be directly limited to the wife herself, and not conveyed to others in trust for her; but it is now settled that a trust estate is a good equitable jointure in bar of dower.

Where an estate tail is limited to a woman for her jointure, she is restricted from alienation or discontinuance by 11 Hen. VII., c. 20, and 32 Hen. VIII., c. 36; on the other hand, if she be lawfully evicted from the whole or part of the jointure lands, she will be entitled to be endowed of the residue of the lands of which, but for such jointure, she would have been dowable, to the value of the lands of which she has been deprived by such eviction.

In consequence of the practical inconveniences attending a limitation of land by way of jointure, it has become usual to create a rent-charge (that is, an annuity charged upon land with a power of distress) for the life of the wife, with the power of distress, and also a power of entry, that is, the right of entering upon the land charged and retaining the possession until the annuity is paid, and further protected by a demise of the land to a trustee for a term of years. Such annuity ought in strictness to be charged upon the land which would otherwise be liable to dower, or upon some part of it.

This arrangement is equally beneficial to the widow and to the heir or devisee of the husband. A more certain income is provided for the widow, and the heir or devisee may enter into the immediate possession and take upon himself the management of the whole estate. This substituted provision by way of annuity is frequently called the wife's jointure.

(*Co. Litt.* and Hargrave's *Notes*; Cruise's *Dig.*; Bacon's *Abr.*)

JUDAISM includes, in its most extensive signification, not only the system of religion which is believed in by the Jews, but also all those laws, moral, civil, political, and ritual, which are contained in the five books of Moses. Some of the peculiar tenets of this religion were imparted to Abraham, the ancestor of the Jewish people; but it did not receive its full development till after the departure of the Israelites from Egypt and their arrival at Mount Sinai, where the Supreme Being imparted to Moses the whole system of the Jewish economy. After the destruction of Jerusalem by the Romans, and the dispersion of the Jews over the various countries of the world, all those laws which related to government, and which could only be enforced in a country where the Jews possessed political power, necessarily became obsolete; and the term Judaism has consequently been restricted to those religious and moral laws which are contained in the Pentateuch, or which have been adopted or retained from tradition, or by inculcation of their rabbis, and which are recognised by the Jews to the present time as the rule of their faith and conduct.

An interesting account of the ceremonial rites and religious and philosophical opinions of the modern Jews (that is, of those who lived during and subsequently to the time of Christ) is given in Allen's '*Modern Judaism*,' 1816.

JUDEX, JUDICIUM. It is of some importance to form a correct notion of the terms *judex* and *judicium* in the Roman writers. The *Judicia* were of two kinds, *privata* and *publica*; the former, having relation to *actiones*, may be generally described as civil actions; the latter were of the nature of criminal prosecutions.

In the *Judicia Privata* the party complainant (*actor*) came before the prætor or other magistrate who had jurisdiction (*jurisdictio*), and made his claim or complaint, to which the defendant (*reus*) might put in a plea (*exceptio*). The prætor then made an order by which he referred the matter to *Judices*, or *Recuperatores*, or *Arbitri*, whose chief office was to ascertain the facts in dispute. The formula, or order of the prætor, was of the nature of a provisional decree: it stated the matter at issue between the parties, and the judgment that was to follow upon the determination of the facts. The plaintiff had to prove his case, or the defendant to prove his plea, before the *judices*. Sometimes there was only one *judex*. The speech of Cicero '*Pro Publio Quintio*' was made before a single *judex*, aided by assessors (*consilium*.)

The *patroni* or orators appeared before the *judices* to support the cause of their clients. The *judices* were sworn to act impartially. Witnesses were produced on each side, and examined orally; and it is clear from the remarks of Cicero ('*Pro Cæcina*,' c. 10), where he is commenting on the evidence in the case of Cæcina, that he had cross-examined and put to confusion an impudent witness on the other side (see also the oration '*Pro Flacco*,' c. 10). It is clear also from the oration '*Pro Cæcina*,' that the inquiry before the *judices* was public. Written documents, such as letters and books of accounts, were produced before the *judices* by way of evidence. (Cicero, '*Pro Q. Roscio*.) When the orators had finished their speeches, the *judices* decided by a majority. The form in which the *judices* pronounced their decision was that of a judgment or decree.

The difference between the *judicium* and *arbitrium* was this: in the *judicium*, the claim, demand, or damages, was a sum fixed; in the *arbitrium* it was a sum uncertain; and this difference was attended with certain variations in the procedure. This is very clearly expressed by Cicero ('*Pro Q. Roscio*,' c. 4).

The *judices* were allowed to have assessors (*consilium*) learned in the law (*juris-consulti*), but they merely advised the *judices*, who alone delivered the decision. In case of doubt as to the law, the *judices* might consult the magistrate under whom they were acting; but as to the matters of fact, the *judices* were the sole judges, and could take no advice from the magistrate ('*Dig.*,' v. 1, 79). Gellius (xiv. 2) gives an amusing account of the difficulty which he felt on being appointed a *judex*, and how he got rid of the business by declaring on oath, as the *judex* always might do, that he could not come to any decision.

We may presume that the *judices* were generally persons qualified by a sufficient education, though they were not necessarily lawyers; but it does not appear that they were named out of any determinate class, and there is good reason for thinking that both parties generally agreed upon the *judices*, or at least had the power of rejecting them. It would seem as if every Roman citizen was considered competent to discharge the functions of a *judex* in civil actions, at least under the emperors: but this part of the subject is not free from difficulty.

Appeals from the decisions of the *judices* were not uncommon. (Ulpian, '*Dig.*,' xlix. 1, 1; Sævola, '*Dig.*,' xlix. 1, 28.)

So far seems pretty well ascertained. Such being the qualifications of the *judices*, and the magistrates who had *jurisdictio* being only annual functionaries, it appears that there was no class of men among the Romans, like our judges, who were the living interpreters of law for a series of years in succession. The *juris-consulti* seem to have kept the Roman law together as a coherent body, and it is from their writings alone that the '*Digest*' is compiled. [JUSTINIAN'S LEGISLATION.]

A court is often mentioned by the Roman writers, the origin and constitution of which, if they could be thoroughly ascertained, would throw great light on the Roman judicial system, and indeed on the Roman polity generally. We allude to the *Judicium Centumvirale*, which in the earlier times of the Republic was a court in which weighty matters of law were decided. This court gradually declined, but was restored by Augustus. The author of the dialogue '*De Causis Corruptæ Eloquentiæ*' speaks of it as most flourishing in his time; but he proves its former decay by observing that there was not a single speech then extant made by any great orator before this court, except one which he mentions. Yet both L. Crassus and Q. Sævola had pleaded before the *Centumviri*. (Cic., '*De Orat.*,' i. 39.) The origin, number, and constitution of this body are not known, though some writers say that the number was 105, three being chosen from each tribe. (Festus, v. '*Centumviralia*.) But there were not thirty-five tribes till A.U.C. 513, and therefore it might be inferred that the *Centumviral* body was of comparatively recent date. However, this does not necessarily follow from the words of Festus; and besides, such an explanation may be nothing more than his attempt to assign the origin of the court, without being able to trace it historically. The *Centumviri* were not *magistratus*, but a college of *judices*, who decided in *Judicia Privata*. The matters which came before them were only *actiones in rem*, or *vindicationes*, not *actiones in personam*, or actions founded on contracts or delicts: consequently the matters brought before them were actions affecting ownership, servitudes (easements), wills, and intestacies. (Cicero, '*De Oratore*,' i. 38, 39.) The *Querela Inofficiosi Testamenti* seems to have

come before this court only. So far as is here stated seems to be pretty clearly made out. A valuable essay on this subject by Hollweg will give further information, and to this work, Tigerström's essay, 'De Judicibus apud Romanos,' Zimmern's 'Röm. Civilist. Process,' and Muhlenbruch's notes to Heineccius's 'Antiq. Rom.' lib. iv. tit. vi., we refer the student.

It is not our purpose to treat at length of the *Judicia Publica*. They were in the nature of criminal prosecutions, in which any person, not disqualified, might be the prosecutor, and in which the verdict was followed by a legal punishment. *Judices* were employed here also, and were a kind of assessors to the magistrate, or the *Judex Quæstionis*, who presided. Both the accuser and the accused, as it seems, might challenge a certain number of the *judices*. Witnesses were examined before them: slaves by torture, freemen orally. The *judices*, at least in the more important matters, voted by ballot: each *judex* put into the urn the tablet of Acquittal, of Condemnation, or the tablet *N. L.* (*non liquet*, "it is not clear"), according to his pleasure. The magistrate pronounced the verdict according to the tablets which made a majority. A lively picture of the intrigues and bribery which were not unusual on such trials is given by Cicero in speaking of the affair of Clodius and the *Bona Dea* ('Ep. ad Attic.' i. 13, 16). The various changes made as to the body from which the *judices* were chosen appear to refer only to the *judicia publica*. [EQUITES.]

There is a distinction between *judicia publica*, *judicia popularia*, *judicia extraordinaria*, and *judicia populi*.

The title "De Officio Judicis" in the 'Institutes' (iv. 17) contains merely general directions for the conduct of the *judices*.

It should be observed that this subject is not free from difficulty. What is above stated must be taken only as correct in the main features. Further inquiry is still wanted on several matters connected with the functions of the *judices*. Enough has been said to enable the reader to compare the Roman *judices* with the modern jury, and to show the difference of the institutions.

(Gaius, lib. iv.; Heineccius, *Syntagma*, &c., by Muhlenbruch (1841); Unterholzner, *Ueber die Rede Cicero für den Schauspieler Roscius*, *Zeitschrift*, &c., i. 248; and his remarks on the difference between the *condictio* and the *actio in personam*, with reference to the *judices*; and Heffter, *Comment. in Gaii librum quartum*, D. 5, l. D. 48. *Inst.* 4, 18.) [INTERDICTION.]

Dr. Pettingall's 'Enquiry into the Use and Practice of Juries among the Greeks and Romans,' London, 1769, may be consulted as to the functions of the Roman *judices* in the *Judicia Publica*. The author's conclusions seem in the main to be correct, though his essay is an ill-arranged and unmethodical production. The 'Attische Process,' by Meier and Schömann, and the essay of Pettingall, may be consulted with reference to the functions of the *Attic Dicastæ*.

JUDGE (from the French *juge*, which is from the Latin *judex*), is a man who presides in a court duly constituted, declares the law in all matters that are tried before him, and pronounces the sentence or judgment of the law. There are judges of the three Superior Courts of Law at Westminster, judges in the Courts of Equity, judges in the Ecclesiastical and Admiralty Courts, and in the County and other courts. Some judges are called recorders, and there are other names, but the name does not alter the nature of the office. When "the judges" simply are spoken of, the judges of the superior courts of common law are meant.

The judges of the superior courts are appointed by the crown. They hold their office during good behaviour, and can only be removed by the crown on the address of both houses of parliament (13 Wm. III. c. 2). Formerly their commissions ceased upon the demise of the crown, but by the 1 Geo. III. c. 23, they continue to hold their office during good behaviour notwithstanding any demise of the crown, and their salaries are secured to them so long as they hold their office.

By various acts of parliament retiring pensions of a determinate amount may be granted to the judges of the superior courts of law, and to the judges in equity. But to be entitled to the pension the judge must have held the office for fifteen years, unless bad health has prevented them from holding office so long.

Judges of courts of record [COURTS] are not liable to prosecution for anything done by them as judges. Nor are they liable to an action for any error in judgment or for wrongful imprisonment, at least when they are acting within their jurisdiction. Judges are punishable for bribery, by loss of office, fine, and imprisonment.

The powers and duties of judges would form the subject of an elaborate treatise. It may be sufficient to observe that in England the judges of the superior courts are so well protected in the discharge of their duty and so sure in their office, as to make them entirely independent of all political and private influence, and they are paid well enough to secure them against all temptation of lucre. Accordingly an instance of misconduct in any judge of the superior courts of law, or any judge who holds a high office, is now seldom or never heard of. The only question that can be raised is, whether the most competent persons are always appointed, and whether persons are not sometimes appointed who, though not absolutely incompetent, are much less competent than others, and sometimes hardly competent. The danger is somewhat lessened by the operation of public opinion, and also of the opinion of the bar, so that the risk of a totally incompetent person

being appointed is not great. The press in this way exercises a wholesome but by no means sufficient check on the Lord Chancellor, by whom nearly all the judges are now appointed. It would be impossible, notwithstanding any burst of public or professional complaint, for any chancellor, however much he might wish to shape his conduct to gain public approbation, to recal an appointment, and a judge, once in office, could not well, by resigning, admit the justice of the animadversions made on his appointment. The evil thus necessarily incident to the possession of unlimited patronage by the chancellor, and to which public attention has been recently called, is inseparable from the practical working of the constitution, and is probably a much less evil than any other mode of appointment that could be suggested.

JUDGES, THE BOOK OF (שֹׁפְטִים : *krītal*, Acts xiii. 20), a book of the Old Testament, which gives an account of the history of the Israelites from the death of Joshua to that of Samson. Joshua did not exterminate according to divine commandment all the nations of Canaan, but allowed each tribe to settle in the district of land allotted to it before the termination of the war. Since the tribes were not united by any national league, and were surrounded by powerful enemies, they were frequently conquered by the neighbouring nations and obliged to pay tribute. But they seldom remained in subjection for any length of time; they still retained much of the valour by which they were originally distinguished; and their patriotic efforts were usually directed or supported by a series of individuals, who were remarkable either for craft, bodily strength, or daring valour. These persons were called *Shophetim*, which is not very well translated by our English word "Judges," since, with the exception of Deborah (Judges, iv. 4, 5), none of them appeared to have exercised the judicial office till the time of Eli, who was also high-priest. After they had delivered their countrymen from their oppressors, they usually retired into private life. (Judges, viii. 23, 29.) The word would be better translated Governors, or Rulers. The most prominent duty of Oriental rulers is to be judges. The Carthaginians called their non-regal governors by the same title, modified by the Latins into *Suffete*.

The book of Joshua consists of two distinct parts. The first, after an introduction on the state of the Israelites after the death of Joshua (ch. i. ii.), gives an account of the exploits of the different judges from Othniel to Samson (ch. iii.-xvi.) There were thirteen judges, excluding Abimelech, who was made king by the men of Shechem (ix. 6), namely: Othniel (iii. 9); Ehud (iii. 15); Shamgar (iii. 31); Deborah (iv. 4); Barak (iv. 6); Gideon (vi. 11); Tola (x. 1); Jair (x. 3); Jephthah (xii. 7); Ibzan (xii. 9); Elon (xii. 11); Abdon (xii. 13); Samson (xv. 20). The second part of the book (ch. xvii.-xxi.) gives an account of an idol that was worshipped first in the family of Micah (ch. xvii.), and afterwards in the tribe of Dan (ch. xviii.); and also a history of a barbarous act committed by the Benjamites of Gibeah, which led to a war between the tribe of Benjamin and all the other tribes, in which the former was nearly extirpated.

The author of the book and the time in which it was written are equally uncertain. Among the Jews there were many prophets whose names are not mentioned in Scripture, and the book was probably contributed to by more than one, though it is commonly ascribed to Samuel. Some have argued, from Judg. xviii. 30, that it could not have been written till the time of the Babylonish captivity; but, comparing this passage with 1 Sam. iv. 11, and Psalm lxviii. 60, 61, it is most likely that it refers only to the captivity of the Ark, and of a part of the tribe of Dan, who were subjected to the Philistines. The last five chapters, also, are clearly supplementary, and were probably added about the time of Solomon. The book does not give a continuous history of the people, and contains many things which could hardly have been written by the same individual. Many of its narratives are repeated in other books of the Old Testament. Compare Judg. iv. 2, vi. 14, xi. 2, with 1 Sam. xii. 9-12; Judg. ix. 53, with 2 Sam. xi. 21; Judg. vii. 21, with Is. ix. 4; Judg. vii. 25, with Ps. lxxxiii. 11. Two or three verses in the song of Deborah are copied almost word for word in some of the Psalms. Compare Ps. lxviii. 8, 9, xcvi. 5, with Judg. v. 4, 5.

The chronology of this book has occasioned considerable difficulty. The period of the Judges is usually estimated at 299 years, in consequence of a passage in the book of Kings (1 Kings vi. 1), in which it is said that 480 years elapsed from the departure of the Israelites from Egypt to the foundation of the Temple by Solomon; though the ancient versions are not all agreed, and the present Septuagint has 440 years. St. Paul, on the contrary, gives 450 years as the period of the Judges. (Acts, xiii. 20.)

The canonical authority of this book has never been disputed. It is placed in all the Hebrew manuscripts immediately after the book of Joshua. It is quoted by Philo and Josephus, and also in Acts, xxxii. 20, and in the Epistle to the Hebrews, xi. 32.

(The *Introductions* of Eichhorn, Jahn, De Wette, Augusti, and Horne; Harenberg, *Einleitung in das Buch der Richter*; Studer, *Das Buch der Richter, grammatisch und historisch erklärt*, 1835.)

JUDGMENT is the sentence of the law pronounced by the court upon the matter in the record, and the remedy prescribed by law for the redress or punishment of injuries; the suit or prosecution being the vehicle by which the injury is brought before the court. Judgments are given under four heads of issues: on Demurrer, where the

facts are confessed by the parties, and the law determined by the court; on Verdict, where the law is admitted and the fact disputed; by Confession or Default, where the defendant admits both the law and the fact; and on Nonsuit or Retraxit, where the plaintiff acknowledges that neither the law nor the facts are sufficient to support his case, and therefore abandons the prosecution.

Judgments are either interlocutory or final. Interlocutory judgments include all those which are given on account of the incomplete state of the case as brought before the court, and which do not go to the absolute merits of the case: such as judgments on pleas of abatement. But the largest class to which this term is applied are judgments which, although they decide the right between the parties, require some other proceeding to determine the amount to be recovered. This proceeding is commonly a writ of inquiry, directed to the sheriff, who therefore impanels a jury, and proceeds to assess the amount of damages to which the party in whose favour the interlocutory judgment has been given is entitled. If, however, the suit is for a specific thing or sum, the decision of the court determining whether the plaintiff is or is not entitled to recover the remedy he sues for, the judgment is final.

By the Common Law Procedure Act, 1852, a plaintiff or defendant having obtained a verdict, judgment may be signed thereon in fourteen days unless otherwise ordered by the judge. The opposite party may prevent judgment from being signed by moving the court for a new trial in case of any objection to the proceedings; for arrest of judgment, if anything bad appears on the record; for judgment *non obstante veredicto*, that is, that judgment may be given in his favour, notwithstanding the verdict, when the plaintiff conceives that a plea of confession and avoidance in which a verdict has been given for the defendant is improper; for repleader, when the pleading failed to raise the material question; or for a writ of *venire facias de novo*, when some form, as by improperly choosing the jury, has been violated. After the expiration of these fourteen days, the plaintiff or defendant may obtain the signature or allowance of the proper officer of the court, stating that the judgment is in his favour. This is called signing judgment.

The nature or form of the judgment varies according to the nature of the action, the plea, the issue, and the manner and result of the decision.

1st. If the issue be for the plaintiff.

If it be an issue at law arising upon a dilatory plea, the judgment is, that the defendant answer over, and is called a *respondeat oster*. Upon all other issues in law, and generally in fact, the judgment is that the plaintiff do recover, which is called *quod recuperet*.

2nd. If the issue be for the defendant.

The issue being on a dilatory plea, whether of law or fact, the judgment is, that the writ or declaration be quashed or the suit be abated; if the issue be on a peremptory plea, the judgment is that the plaintiff take nothing, which is called a judgment *nil capiat*. When judgments are given by default, or confession without issue, if for the plaintiff, they are *quod recuperet*, if for the defendant, *nil capiat*.

Besides the question at issue being decided by the judgment, the costs of the suit are generally directed to be taxed and paid by the party against whom the judgment is delivered. In addition to this, the judgment, when given for the plaintiff, orders that the defendant "be in mercy,"—that is, amerced or fined for his delay of justice; and when for the defendant, that the plaintiff "be in mercy" for his false claim.

Judgment being signed, the party in whose favour it is given may sue out execution thereon, directed to the sheriff of the county where the property to be taken is situated. At common law, the goods and chattels of a debtor under a writ of *fiery facias*, and the growing profits of the land under a *levary facias*, could alone be taken in execution by a judgment creditor for debt or damages. The remedy was extended by the 13 Edw. I. stat. 1, c. 18 (West. 2), to the creditor over a moiety of the real property of the debtor, for which purpose a writ called an *elegit* was created, including all freehold estates and interests which the debtor held in severalty, coparcenery, or in common, and all rent charges; but copyholds were held not to be liable to be taken in execution under this writ. By a fiction of the law, judgments were considered to take effect from the first day of the term in which they were signed, and therefore a purchaser might have his estate encumbered by a judgment acknowledged subsequently to the purchase. To remedy this injustice, it was enacted by the Statute of Frauds (29 Car. II. c. 3), that any judge who should sign judgments, should at the time of signing set down the exact date thereof, which date should be also written on the margin of the record when the judgment was entered, and such judgments should operate from the date appearing on the margin. As, however, this did not compel the plaintiff to bring in the judgment roll, it was almost impossible for purchasers to discover what judgments existed against the lands about to be conveyed. An Act, therefore, was passed (4 & 5 Wm. & Mary, c. 20), afterwards made perpetual by the 7 & 8 Wm. III. c. 36, which directed that the clerk of the Court of C. B., the clerk of the Dockets of the Court of B. R., and the master of the office of pleas in the Court of Exchequer, should keep an alphabetical list or docket of all judgments in their respective courts, entered according to the names of the defendants; and that no judgments should affect lands in the hands of *bona fide* purchasers,

unless so docketed according to the Act. How this law has been altered by recent statutes will be hereafter considered. For the purpose of discharging a judgment, the proper mode is to enter up satisfaction on the court rolls; but a deed of release will have the same effect although the judgment be allowed to remain; and it has been held that a release of all suits is a complete discharge of all unsatisfied judgments. If execution be not sued out within a year and a day of signing the judgment, it must be revived by a writ of *scire facias*; and a judgment was presumed to be satisfied after a lapse of twenty years from the signing or the last revival, which is now confirmed by the statute 3 & 4 Wm. IV. c. 27.

The entering the judgment on record, except in the cases specified by the Act, where the lands in the hands of purchasers are to be affected, is not absolutely necessary. But to support a writ even brought for the purpose of reversing the judgment, the judgment must be entered on the records of the court.

Recent statutes have introduced great changes in the law of judgments as they affect real property; but as the same rules which existed before those enactments are still under certain circumstances capable of application, it may be useful first to consider how judgments then stood.

A judgment at the time of entering up became a general lien upon all property, real and personal, which the debtor then held or subsequently acquired, and gave the creditor a legal right, so long as the judgment remained on the records of the court and unsatisfied, to enter upon and reduce into possession any such property, by suing out the writ of *fiery facias*, if the goods and chattels of the debtor were to be taken in execution, or the writ of *elegit* as to his real estate, thereby changing that which was before a naked right into an absolute interest, limited nevertheless to the amount of the debt or damages for which judgment was originally entered up.

As to personal estate, it was enacted by the 16th section of the Statute of Frauds, that the goods of the debtor should be bound by a judgment only from the time of taking out execution. And on the interpretation of this clause it was held that chattel interests in land were included under the term goods. This clause still remains in full effect, although in the case of a fraudulent assignment after entering up judgment and before execution, a court of equity would assist the judgment creditor to follow the goods into the hands of the assignee.

The rights of the judgment creditor existing only at law over the personal property of the debtor, which was afterwards extended to a moiety of the real estate, at law the legal estate was only affected, and therefore, by the subsequent creation of trusts, the judgment creditor was frequently prevented from obtaining that remedy at law against the debtor to which he otherwise would have been entitled. To remedy this inconvenience, and enable the judgment creditor to obtain execution on the beneficial interest in any portion of the property of the debtor, it was enacted by the Statute of Frauds that execution should be delivered of all such lands, tenements, rectories, tithes, and hereditaments, as any other person or persons should be seised or possessed of, in trust for him against whom execution was so sued, like as if the debtor had been seised of such lands and of such estate as they be seised of in trust for him at the time of the execution sued. On the interpretation of this statute, it was held that an equitable interest in a term of years was not included within its limits, and only such trust estate as the debtor was interested in at the time the execution was sued out, and in which he had the sole beneficial interest. In this case the judgment creditor has no execution at law, but he might come into a court of equity and claim the same satisfaction out of the equitable interest as he would have been entitled to at law if it were legal. As however the sole right of coming into a court of equity was based on the failure of the law, it was necessary that the judgment creditor should forfeit his title to the utmost by suing out his writ of *elegit* before the court would listen to any application to remove the legal impediment. Upon the same principle that it assisted the creditor who had no relief at law, the court of equity did not permit a judgment against a trustee, though at law a lien upon the estate, to affect the beneficial interest of the cestui que trust.

As under the last mentioned clause of the Statute of Frauds a judgment did not affect the legal estate in the hands of the trustee, until the writ was absolutely deposited in the hands of the sheriff, a purchaser of the equitable estate without notice might by getting in the legal estate protect himself against prior judgments; but if the purchaser bought with notice of the judgment, no acquisition of the legal estate would protect him. Equities of redemption were decided to be not such trust estates as to be included by the Statute of Frauds, the debtor not having the sole beneficial interest.

In the case of lands contracted to be sold, the purchaser is relieved in equity against judgments entered up subsequently to the contract; and also where land is conveyed to trustees for sale, whose receipts are to be sufficient discharge, the purchaser will not be bound by any subsequent judgments of which he has even express notice.

Until the passing of the acts 1 & 2 Vict. c. 110, 2 & 3 Vict. c. 11, and 3 & 4 Vict. c. 82, the law of judgments remained in the main unchanged. By them decrees and orders of Courts of Equity and rules of Courts of Common Law, and orders of the Lord Chancellor in matters of bankruptcy and lunacy, are given the effect of judgments, and the security of the creditor has been extended from a moiety to

the whole of the debtor's lands, including copyholds, making leaseholds bound in the same manner as freeholds. And as all lands are included by the acts, over which the debtor may have a disposing power, judgments against a tenant in tail are binding on his issue; for the tenant might at any time have barred the entail. So also were equities of redemption and trust estates, in which the debtor had only a partial interest. After passing this act a question was raised whether stock was comprised in which the debtor had only a partial interest, but this was set to rest by a clause of the second act, mentioned above, which distinctly declares that the interest of the judgment debtor, whether in possession, remainder, or reversion, in any stocks, funds, or shares, as also in the dividends and annual proceeds of such stocks, &c., is to be liable to the judgment, and that stock standing in the name of the accountant-general is to be in the same position. Money and securities for money (except where deposited in the hands of a third person as a trustee) can also be taken in execution. But the greatest alteration which recent statutes have worked is changing the effect of judgment before execution is sued out, from a general lien to a specific charge upon the "lands, tenements, rectories, advowsons, tithes, rents, and hereditaments" of which the judgment debtor may, at the time of entering up judgment, or at any time afterwards, be possessed, of any estate whatsoever, at law or in equity, or over which he may have any disposing power. All the judgments are made binding on the persons against whom they are entered up, and against all persons claiming through them, the judgment creditor being entitled to the same remedies in a court of equity as if the debtor had by writing agreed to charge the lands, &c. The creditor is not however to proceed in equity to obtain the benefit of such a charge until the expiration of one year from the time of entering up such judgment; and in case of bankruptcy, the judgment, unless entered up one year, is to give no preference to the judgment creditor beyond creditors for simple contract. A special proviso excepts purchasers, mortgagors, or creditors previous to the time when the act came into operation; and with respect to purchasers for valuable consideration without notice, the rules of equity remain unaltered.

A judgment creditor, applying now for remedy to the Court of Chancery, will not be obliged to sue out the writ of *elegit*, for that which is agreed to be done is considered by a Court of Equity as actually performed, and the judgment creditor has therefore, by virtue of his judgment alone, an equitable estate. If however a judgment creditor, having obtained any charge, or being entitled to the benefit of any security, should, before the property so charged or secured is converted into money and applied towards the payment of the judgment debt, cause the judgment debtor to be arrested, the benefit of such charge or security is deemed relinquished. The extent of such charge goes now to the interest at the rate of four per cent. on the judgment debt, as well as to the debt itself.

The dockets which existed since the 4 & 5 W. & M. are now finally closed, and no judgment, decree, or order, which might be registered under the 1 & 2 Vict. c. 110 (see 18 & 19 Vict. c. 15, s. 4), can affect purchasers, mortgagors, or creditors, unless and until a memorandum or minute of the judgment, &c., with the person's name against whom and the date when it was recovered, is left with the proper officer of the proper court, who is to enter the same in a book kept for the purpose, in an alphabetical order by the name of the person whose estate is to be affected. In order to keep alive old docketed judgments, it was made necessary to register them according to this provision before a certain time fixed by the act, or they would be deemed satisfied.

Under the old law a purchaser was bound by undocketed judgments of which he had notice, but it is expressly provided by the late acts that the judgment creditor shall not take advantage of the extended remedies unless the judgment be duly registered according to their provisions. The necessity for searching for judgments on the transfer of property is also greatly reduced, for the 2 & 3 Vict. c. 11, requires all judgments to be re-registered every five years from the date of the last registry, otherwise they are to be considered as void against purchasers, mortgagors, and creditors; and by the act 18 & 19 Vict. c. 15, s. 5, notice of any judgment not duly re-registered will not avail against purchasers, mortgagors, or creditors. The provisions for registration, it must however be remembered, refer to the remedies which the judgment creditor may have against purchasers for valuable consideration with notice; but as between the creditor and the debtor, or his representatives or volunteers, the judgment remains in full effect until twenty years from the time of entering up or last revival. The position in general of judgment creditors among themselves before the late acts depended on the time when they respectively sued out execution; but in a suit for the general administration of assets the judgment creditors took priority according to the time of entering up their judgments. Now as they are entitled to such remedies in equity as if the debtor had by writing charged his land, they take priority in respect of their judgments from the times of registration. It has been questioned whether a subsequent judgment creditor without notice having sued out his writ of *elegit* is not entitled to priority over an equitable mortgagee, but the point has been decided in favour of the latter, upon the principle, that although the judgment creditor by his writ of *elegit* obtained possession of the legal estate, and thereby in equity, under the ordinary rules, could claim a priority to a prior equitable incumbrance of which he had no notice, yet that the legal

estate which the creditor obtains under an *elegit* is only such a one as the debtor himself had power to grant, and therefore liable to all prior equities. (*Whitworth v. Gaugain*, 3 Hare, 461.)

By these statutes judgments of the courts of the counties Palatine of Lancaster and Durham are to have the same effect as judgments of the superior courts of Westminster. But no judgment of those courts is to affect lands in the hands of purchasers, mortgagors, or creditors, unless a memorandum of such judgment be left with the prothonotary or proper officer, who is to register the same in a book kept for the purpose.

Judgments or rules or orders of inferior courts of record, in which a barrister of not less than seven years' standing shall preside, may receive the same effect as those of a superior court by a judge's order to remove them into a superior court. But until execution be actually sued out, they will not affect lands in the hands of purchasers, mortgagors, or creditors, except so far as they would affect them as judgments of an inferior court.

In criminal proceedings, after trial the defendant can move in arrest of judgment at any time before judgment is pronounced, but this can only be done upon error appearing on the face of the record, and no motion of this sort can be made in the defendant's absence unless a verdict is found in which the jury reserve a point for the consideration of the court. After the judgment is recorded, a writ of error is necessary before it can either be reversed or altered. Formerly no judgment affecting the liberty of the individual could be pronounced in his absence, but this has been altered by the 11 Geo. IV. and 1 Wm. IV. c. 70, which enacts that upon trials for felonies or misdemeanours judgment may be pronounced whether the person affected be present or absent, except only in such cases of information as are filed by leave of the Court of Queen's Bench, or in cases of information filed by the attorney-general, where he prays that judgment may be postponed. The judgment of the court extends to the life and liberty of the offender according to punishment decreed to the offence against which the judgment is delivered. In some cases it extends to the compensation by forfeiture of the lands or goods, or both, of the offender; others induce a disability of holding offices, or fix a lasting stigma on the offender; and a large proportion are merely pecuniary by stated or discretionary fines.

On the subject of judgments see Chitty's 'General Practice'; Stephen, 'On the Principles of Pleading in Civil Actions'; Sugden's 'Vendors and Purchasers'; Priedaux, 'On the Law of Judgments as they affect Real Property.'

JUDICIAL COMMITTEE. [DELEGATES, COURT OF; PRIVY COUNCIL.]

JUDICIAL SEPARATION. [SEPARATION, JUDICIAL.]

JUDICIARY. [COURTS.]

JUDITH, an apocryphal book of the Old Testament, contains an account of the invasion of Syria and Judæa by Holofernes, general of Nabuchodonosor, king of the Assyrians, and particularly of the siege of Bethulia, a town in Judæa; and of the destruction of the Assyrian army, and of the death of Holofernes through the courage and stratagem of Judith, the widow of Manasses, and an inhabitant of Bethulia. The historical and geographical difficulties of this book are so great, and its narrative so improbable, that a great number of critics are disposed to consider it as a religious romance, probably written in the time of the Maccabees, to encourage the Jews in their struggles against the Syrian monarchs. Grotius considers it an allegory, written in the time of Antiochus Epiphanes; and that "by Judith is meant Judæa; by Bethulia, the temple or house of God; and by the sword which went out from thence, the prayers of the saints; that Nabuchodonosor denotes the Devil; and the kingdom of Assyria the Devil's pride," &c. Montfaucon ('*La Verité de l'Histoire de Judith*'), Huet ('*Dem. ev. Prop.*' iv., p. 366), and Priedaux ('*Connection*,' vol. i., pp. 65-74), maintain, on the contrary, that it is a true history. Priedaux considers Nabuchodonosor to be the same person as Saosduchinus, the son of Esarhaddon, and grandson of Sennacherib; and Arphaxad, who is represented in Judith as the king of Media, to be only another name for Deioces. But in opposition to this, it should be remarked that there are many passages in the book which refer to a time subsequent to the Babylonian captivity. Josephus, also, who seldom neglects an opportunity of extolling the valour of his countrymen, takes no notice of this story.

The book of Judith was originally written in Chaldee, from which it was translated into Latin by Jerome. It was also translated into Greek and Syriac. The English translation in the authorised version was made from the Greek, and differs in many respects from the translation of Jerome, which is still extant in the Latin Vulgate.

There is a great similarity between the history of Judith and a tale which Quintus Curtius tells us respecting the death of Spitamenes (viii. 3).

(The *Introductions* of Eichhorn, Jahn, De Wette, Bertholdt, and Horne.)

JUGGERNAUTH, or more correctly Jagannatha, though probably a relic of Buddhism, is a comparatively modern idol, of whom the worship dates from a little before the Christian era. Jagannath, the lord of the world, is believed to be an incarnation of Vishnu, who under this name, with the assistance of his brothers Bala-Rama and Krishna, conquered Bahar. These incarnations, however, are very con-

fused; Bala-Rama is sometimes identified with Krishna, and Krishna is a moiety of Vishnu. In Orissa Jagannath is known as Ram Chandra. Rama was a king of Oude, whose queen, Sita, having been carried off by the giant Ravana, was rescued by Bala-Rama, under the form of the monkey Hameman. From these come the three idols, Rama Chandra or Jagannath, Bala-Rama, and Sita. The idols themselves are ugly wooden busts of gigantic size, that of Bala-Rama is six feet high, Jagannath five feet, and Sita four feet. The image of the first is painted white, of the second black, and that of Sita yellow. The faces are large; the eyes of Jagannath are round, those of the other two are oval, from the ears of the males arms project horizontally forward, but the female lacks even this approach to the human form. A new image, according to Col. Phipps, in the 'Asiatic Journal' for March, 1824, is made about once in every seventeen years, from a Nim tree "on which no crow or other carrion bird has ever perched." Another tradition, related by Mr. Stirling, in 'Asiatic Researches,' vol. 15, says that Jagannath, or Vishnu, lived in Orissa under the form of Nil Madhava; his fame excited the attention of Indradyumna, Maharajah of Oujein, who desired to worship at the sacred shrine. On his arrival Madhava had disappeared, but in a dream he was told a fresh avatar would shortly take place, and accordingly a log of the Nim tree (*Melia azadirachta*) was seen to approach the coast, on which were seen conch shells, the lotus, &c., which was accepted as the new avatar, removed to a consecrated place, and on the first blow of the sacred axe it split into the three images already named, requiring nothing but the characteristic colouring.

The great temple of Juggernaut is said to have been built in A.D. 480, but it became completely buried in sand, and remained so until 1198, when it was restored. But Col. Sykes maintains, from no allusion ever being made to it, that it could not have existed in the 5th century; and no part of the present temple appears to be earlier in date than the 11th or 12th century. It stands in the sea-port town of Púro (Pooree), in the province of Orissa, and is a huge architectural mass, containing a sort of pyramidal tower, 210 feet high, built of coarse red granite, and covered with a rough coating of chunam, with two square pyramidal buildings adjoining, the top surmounted by an urn. They stand in the centre of a quadrangle enclosed by a high stone-wall, each side of which is 650 feet long, and 30 feet high. In front of the temple stands a column of elegant proportions, brought from an ancient temple to the sun at Kanarak. It is polygonal, of light and elegant appearance, and is surmounted by a figure of the monkey-deity Hameman. The material is a dark-coloured basalt. The entrances of the temple are flanked by colossal figures of lions or griffins, with mythological porters resting on their clubs carved on the side posts. It is a very conspicuous land-mark, and is of considerable importance to navigators on the flat and uniform coast where it is situated. The country, to the distance of about a mile from the sea, is a waste of deep loose sand; farther inland it consists of low sand-hills covered by a thick forest of dwarf-trees.

The festival of Jagannath, called Ruth Jatra, takes place every year, and the number of pilgrims is still very great, though much less than formerly, when Dr. Carey estimated them at 1,200,000; but in 1846 there were 180,000, and in 1849 and 1850 above 100,000. The idols are, in the first instance, dragged from their pedestals without decency or reverence, thrown down the steps, and hauled through the mud, until they reach the cars provided for each of them. That of Jagannath is 45 feet in height, that of Bala-Rama 44 feet, and that of Sita, or Subudra, 42 feet. The first has sixteen wheels, the second fourteen, the third twelve; and the platforms decrease in similar proportions. A small rail surrounds the platform of each car, in which an opening of a few feet is left in front of the idols. Cables are attached to the cars, and by these the pilgrims drag it about a mile and a half to its destination, and then back again, the whole procession occupying three days.

Mill, in his 'History of British India' (b. ii. c. 6), says, "It is customary for numbers of congregated persons to throw themselves under the wheels, and even fathers and mothers with their children in their arms. The chariot passes on, as if no impediment existed, and crushing them to death is supposed to convey them immediately to heaven." Professor H. H. Wilson says (in his edition of Mill's work), "this practice is modern: Jagannath himself is modern, and has no place in the Vaishnava Puranas. It is not improbable that the present shrine attained reputation as a place of pilgrimage no longer ago than a century" (that is, in 1740). Self-immolation has been prohibited by the government for many years, but numbers perish during the pilgrimage from disease or want of food. Lieut. Burton says, ('Pilgrimage to El Medinah and Mecca,') that "at Jaganath they worship a pyramidal black stone, fabled to have fallen from heaven, or miraculously to have placed itself on the place where the temple now stands;" and he seems to consider it as of the same nature as the Black Stone at the Kaaba of Mecca, which he thinks is an aërolite.

(Mill, *History of British India*, by Wilson; *Geographical, Statistical, and Historical Account of Orissa Proper, or Cuttack*, by A. Stirling, in *Asiatic Researches*, vol. xv.; W. F. B. Laurie, *The Idol Shrine*, 1851.)

JUGLANDIN. A non-azotised body of uncertain composition contained in green walnuts; the extract of walnuts is in fact impure juglandin. In contact with the air it becomes rapidly black, and on

this account is sometimes employed as a hair-dye. It is also occasionally used in medicine.

JULIAN PERIOD is a term of years often employed in chronology, in order to avoid the ambiguity attendant on reckoning any time antecedent to our æra. The Julian Period consists of 7980 years, and is reckoned as having begun 4713 years before our æra; so that the present year 1860 corresponds to 6573 Jul. Per. The æra of the creation, or Anno Mundi, which has been used by Christian and Jewish writers, cannot be considered as a fixed point, as chronologists and controversialists are not agreed as to the precise time of its commencement, some placing the creation 4004 years B.C., others, such as the early Alexandrian Christians, 5502 B.C., and the Greeks and Russians at 5508 B.C. The Julian Period is produced by the multiplication of the lunar cycle 19, solar cycle 28, and Roman indiction 15. [PERIODS OF REVOLUTION.]

JULY, now the seventh, was originally the fifth, month of the year, and was called by the Romans, in regard to its numerical station, *Quintilis*. Mark Antony altered the name to Julius, the gentile name of Caius Cæsar, the Dictator, who was born in it. So Festus, "*Julium mensem appellarunt quod eo mense dicitur Julius natus.*"

In the old Latin or Alban calendar, *Quintilis* had a complement of 36 days. Romulus reduced them to 31; Numa to 30; but Julius Cæsar restored the day of which Numa had deprived it, which it has ever since retained.

Our Anglo-Saxon ancestors called July *Mæd-monath*, "mead month," from the meads being then in their bloom; and *litha-æftera*, "the latter mild month," in contradistinction to June, which they considered and named as "the former mild month."

JUNE, the sixth month of the year, named from the Latin *Junius*. Ovid, in his 'Fasti' (vi. 25) makes Juno assert that the name was expressly given in honour of herself:—

"Ne tamen ignores vulgique errore traharis,
Junius à nostro nomine nomen habet."

In another part of the 'Fasti' (vi. 87) he gives the derivation à *junioribus*; as May has been derived from *Majores*:—

"Junius est juvenum; qui fuit ante senum."

Those who derive the name from Junius Brutus, who began his consulship in this month, forget that, according to tradition, it had received the appellation long before.

In the old Latin or Alban calendar June was the fourth month, and consisted of 26 days. Romulus is said to have assigned it a complement of 30 days. Numa, who made it the sixth month, deprived it of one day, which was restored by Julius Cæsar, since which time it has remained undisturbed.

The Anglo-Saxons had several names for the month of June. They called it *sear-monath*, "dry month"; *midsummer-monath*, "midsummer month"; and *litha-ærra*, "the earlier mild month," in contradistinction to July.

In this month is the summer solstice. Pitiscus tells us that in the Roman times the month of June was considered to be "nuptiis aptissimus."

JUNIPERUS COMMUNIS, *Medical Properties of*. The wood of the root and stem, the twigs or tops, with the leaves attached, and the fruits (*galbuli*, incorrectly termed berries), of the common juniper, all possess a peculiar aromatic flavour and odour, due to two peculiar oils, differing in their degree of volatility, which in chemical composition resemble French oil of turpentine, being destitute of oxygen, and therefore only carburets of hydrogen. In Britain the twigs and fruits, and oils thence obtained are officinal; on the continent the wood of the root and stem is used. From both, but especially the roots and thick branches, more oil can be extracted than from the wood of the trunk. This last is used to burn as incense and for pastiles. Articles of furniture made of it are not eaten by insects, as is the case also with cedar. The fruits are imported both from the north and south of Europe. Those from the latter are richest in volatile oil. The chemical analysis of Trommsdorff gives of volatile oil 1.0, wax 4.0, resin 10.0, a peculiar kind of sugar with acetate and malate of lime 33.8, gum with salts of potash and lime 7.0, lignin 35.0, water 12.9. The fruits require two years to ripen, but at the end of the first year, while yet green, they are richest in volatile oil; and they should be collected at that time. Much of the volatile oil is converted into resin during the second year. [GENEVA.] The fruits are seldom given, but may be rubbed up with sugar. The oil is, however, one of the most powerful of diuretics, four drops acting strongly on the kidneys. But the compound spirit of juniper is the form mostly employed for its exhibition. The preparation, according to the 'London Pharmacopœia,' is made by digesting the ingredients, consisting of the oil of juniper, with oils of caraway and fennel; but, according to the Edinburgh and Dublin Pharmacopœias, by distilling the fruits: the last is a more potent preparation.

JUNIPERUS SABINA, *Savine, Properties of*. Of this plant, the tops, fresh or dried, are used. They contain a volatile oil and resin. The odour is more like cajepout oil than like turpentine. The fresh plant is more active than the dried. Bruised or reduced to powder these leaves excite a rubefacient action to whatever part they are applied, and acute inflammation with ulceration is the result of their prolonged application. But action on the nerves, especially of the uterus, takes

place, as well as increased activity of the veins, particularly of the liver. The external use of sabine, or savine, is proper under skilful direction, more particularly when diffused through fats or cerates, mostly to keep up a *perpetual* blister. But the internal use of savine is one of the most dangerous forms of popular quackery—often causing death. Its employment cannot be too much reprobated.

JUNO. [HERA.]

JUNO, one of the group of small planets which revolve between Mars and Jupiter. [ASTEROIDS.]

JUPITER. [ZEUS.]

JUPITER, the name of one of the old planets, the largest of all the bodies, except the sun, in the solar system. The astronomical history of this planet (or of any other, except the newly-discovered small planets) is so completely entangled in that of the progress of astronomy in general and pure mathematics, that it would be useless to attempt any separation. In the article GRAVITATION will be found the most remarkable points of what an astronomer would call the *theory* of Jupiter, meaning the explanation of his motions by means of the law of gravitation. We shall here confine ourselves to the statement of the elements of the planet's motion, and that of the satellites.

The figure of Jupiter is sufficiently oblate to appear of a sensibly spheroidal form in a moderate telescope. According to the recent researches of Mr. Main, the axis of revolution is to the equatorial diameter in the proportion of 15.84 to 16.84. The apparent equatorial diameter varies between half and three-quarters of a minute, being 37".91, when the planet is at its mean distance from the earth. The real equatorial diameter is 11.46 times that of the earth, or upwards of 91,000 miles. Its mean density is nearly the same as that of the sun or about one-quarter of that of the earth.

The mass of Jupiter, from the time of Newton to the present, was supposed to be to that of the sun in the proportion of 2 to 2141; but the recent observations of various astronomers, concluding with those of Mr. Airy, contained in the 'Memoirs of the Astronomical Society,' make it somewhat greater. Mr. Airy's result is that the mass of Jupiter is to that of the sun in the proportion of 1 to 1046.77, or 2 to 2094 nearly.

Elements of the Orbit of Jupiter.

Epoch 1799, December 31, 12^h mean astronomical time at Paris. Semiaxis major 5.20115524, that of the earth being assumed as the unit.

Excentricity .0481621; its secular increase (or increase in 100 years) .0001594.

Inclination of the orbit to the ecliptic 1° 18' 52"; its secular diminution 23".

Longitudes from the mean equinox of the epoch (1) of the ascending node 98° 25' 44".90; its secular increase (combined with the precession) 3430"; (2) of the perihelion 11° 7' 38".26; its secular increase (combined with the precession) 5710"; (3) of the planet (mean) 81° 52' 19".33.

Mean sidereal motion in 365 $\frac{1}{4}$ days 109256".59; sidereal revolution 4332.5848212 mean solar days.

When observed with a telescope of sufficient power, the surface of this planet is perceived to be diversified by faint belts extending in parallel directions across his disc. These belts are observed to vary in magnitude and number; but in general three belts are conspicuous, forming a zone across the body of the planet, and extending in a direction nearly parallel to the plane of his orbit. Jupiter, like several of the other planets, is observed to revolve on a fixed axis. The earliest surmise of this fact is due to Kepler, who inferred, from the rapid motion of the satellites of the planet compared with the slower motion of the moon around the earth, that Jupiter rotates more rapidly than the earth does. The subsequent observations of astronomers with the telescope have confirmed this interesting conjecture. Hooke appears to have first discovered the rotation of the planet. In the month of May, 1664, while engaged in a telescope survey of the planet he discovered a small spot on the largest of the three belts, which, in the course of two hours, travelled from east to west over a space equal to about half the diameter of the planet. It was reserved for Cassini to assign the period of rotation with some degree of precision. Having found that the planet generally presented a very altered appearance after the lapse of five hours, he concluded that the time of rotation must be somewhere about ten hours. From observations of a spot near the southern belt of the planet, he found that in 12^d 0^h 4^m, it returned to the same position on the disc. During this interval the planet must have effected twenty-nine complete rotations. It hence resulted that the time of rotation amounted to 9^h 56^m. The subsequent observations of Cassini indicated that the spots, besides participating in the rotation of the planet, have a proper motion on his surface. The elder Herschel established the existence of this fact beyond all doubt. He found that the time of rotation as indicated by the return of the spots to the same position on the disc fluctuated between 9^h 55^m 40^s and 9^h 50^m 48^s.

The most reliable determination of the time of rotation is due to Mr. Airy, whose observations of the planet were made at Cambridge in the years 1834-5. Having watched the motion of a spot on the apparent lower belt from December 16, 1834, to March 19, 1835, during which period the planet had effected 225 complete rotations,

he hence concluded that the time of rotation is 9^h 55^m 21.3^s. The inclination of Jupiter's equator to the ecliptic amounts to 3° 5' 30",

The telescopic appearance of Jupiter seems to indicate that the body of the planet is enveloped in a cloudy atmosphere of great density. This opinion is strengthened by the variable appearance of the spots on his surface. Sir William Herschel supposed that the spots represent dense masses of clouds. He ascribes their variable motion to the prevalence of winds in the atmosphere of the planet, which blow periodically in the same direction. He also endeavours to explain the gradual increase observable in the motion of a spot after its first appearance, by the circumstance, that some period of time must necessarily elapse before the spot can acquire the full velocity of the wind by which it is impelled. From his observations of the spots, he inferred that in some instances the winds travel at the rate of somewhat more than 200 miles in an hour. This, however, does not exceed the velocity of occasional winds on the earth's surface. Mr. De La Rue has executed an admirable delineation of the physical features of the planet.

The discovery of the important fact that Jupiter is accompanied by four satellites is due to Galileo. Having examined the planet with a new telescope on the 7th of January, 1610, his attention was drawn to three small but very bright stars which appeared in the vicinity of the planet, two on the east side of his disc, and one on the west side. On the following evening he again perceived the stars, but their arrangement with respect to the planet was not the same as it was previously. On the 13th he perceived four stars in the vicinity of the planet. By continuing his observations he established beyond all doubt the fact that the four stars seen by him revolved regularly around the planet, and he even arrived at a rough approximation of their times of revolution.

The four satellites of Jupiter appear to revolve on axes, each in the time of its revolution round the planet, in the same manner as our moon. The elements of their orbits are as follows (Baily, 'Astron. Tables and Formulæ'): the units of time, length, and mass being the earth's mean solar day, the planet's equatorial semidiameter, and the planet's mass.

Sat.	Sidereal Revolution.		Mean Distance.	Mass.	
		More nearly.			
	d.	h. m.	d.		
1	1	18 28	1.769137788148	6.04853	.0000173281
2	3	13 14	3.551810117849	9.62347	.0000232355
3	7	8 43	7.154552783970	15.35024	.0000884972
4	16	16 32	16.688769707084	26.99835	.0000426591

The first satellite has no sensible excentricity, and its orbit is very nearly indeed in the plane of Jupiter's equator. The second has no sensible excentricity; the inclination of its orbit to the planet's equator is under half a minute, and its nodes have a retrograde revolution of about thirty years. The third has a small but very variable excentricity, and the line of apsides has a direct but variable motion. The inclination of its orbit is under a quarter of a minute, and the nodes make a retrograde revolution in about 142 years. The fourth has a greater excentricity, and the direct mean motion of its apsides is nearly three-quarters of a degree per annum. The nodes made by its orbit with that of the planet have a direct motion of 4 $\frac{1}{2}$ minutes per annum, and the inclination of the orbit to that of Jupiter is 3° nearly.

The apparent diameters of the satellites were determined by W. Struve with a micrometric apparatus attached to the great refractor of the Dorpat Observatory. The following are the apparent diameters which they would subtend if viewed at the mean distance of the planet from the earth:—

Apparent diameter of 1st satellite		1".015
" " 2nd "		0".911
" " 3rd "		1".488
" " 4th "		1".273

These measures indicate the absolute diameters of the satellites, counting outwards from the planet, to be respectively, 2429 miles, 2180 miles, 3561 miles, and 3046 miles.

In consequence of the smallness of the angle by which Jupiter's equator is inclined to the ecliptic, and of the nearness of the orbits of the satellites to the plane of the equator, all the satellites, except the fourth, which sometimes escapes, undergo one eclipse once in every revolution. Since [ECLIPSE] this is caused by the entry of the satellite into Jupiter's shadow, the eclipse is independent of the earth's position, and the observation can certainly be made, unless Jupiter be too near to the sun. It is found that an immersion or emersion is not visible, generally speaking, unless Jupiter be as much as 8° above the horizon, and the sun as much as 8° below it. It never happens that both the immersion and emersion can be observed, in the case of the first satellite, and rarely in that of the second; though it is otherwise with the third and fourth. The reason is, that the planet itself

always hides a part of its own shadow, and the first satellite is so near the planet that it must either enter or leave the shadow behind the planet; which also happens, for the most part, in the case of the second satellite. Before the planet is in opposition its shadow is on the western side of the planet, and after opposition on the eastern; while before the opposition immersions only are visible, and after opposition emersions, in the case of the first and second satellites. The eclipses of the four several satellites last about $2\frac{1}{4}$, $2\frac{3}{4}$, $3\frac{1}{2}$, and $4\frac{1}{4}$ hours, one time with another. For the use of these eclipses in determining LONGITUDE, see that word.

JURISDICTION. This term is the Latin word *Jurisdictio*, which simply signifying the "declaration of jus or law," was used by the classical writers to express the "administration of Justice" (Cic. 'Fam.' 2 ep. 13 ad fin.) as well as "legal authority." (Cic. 'Agrar.' 2, c. 36; Sueton, Calig. c. 16). He who had *jurisdictio* was said "jus dicere," to "declare the law." The whole office (*officium*) of him who declared the law was accordingly expressed by the word *Jurisdictio*. (D. 2, 1.). *Jurisdictio* was either voluntary (*voluntaria*) or litigant (*contentiosa*). The *jurisdictio voluntaria* related to certain acts, such for instance as those forms of manumission and adoption which must be done before a *magistratus* in order to be valid; it is therefore described in the law books as an *actio legis* (D. 1, 16, 3, & D. 1, 20, 1). The *jurisdictio contentiosa* related to litigation, and such legal proceedings were said to be "in jure," before the *magistratus*, as opposed to the proceedings before a *judex*, which were said to be "in judicio." The *magistratus* was said "jus dicere" or "reddere," when he exercised his functions; and "magistratus" and "qui Romæ jus dicit" are accordingly convertible terms (Warnkœnig, 'Institutiones Juris Romani,' lib. iv. cap. i. tit. vii., and Abdy's 'Law of Civil Procedure among the Romans,' chap. ii.) Jurisdiction in England, which is defined by Coke to be "Potestas de Publico introducta cum necessitate Juris dicendi," 10 Co. 73, and is explained to be an "authority or power which a man has to do justice in causes of complaint brought before him," means an authority which a court of law or equity has to decide matters that are litigated before it or questions that are tried before it. The courts at Westminster have jurisdiction all over England and Wales; but the jurisdiction of other courts is limited by being confined to certain limits of space and to certain kinds of causes or matters in dispute. When the jurisdiction of a court extends all over England, it may still be limited as to the kind of causes which it tries. Thus, the superior courts of law and the courts of equity have their several jurisdictions as to matters which they hear and determine. [EQUITY.] The ecclesiastical courts also have their separate jurisdiction; and other courts, such as the Probate and Divorce Court, Admiralty Court, the Court of Insolvency, Borough Courts, County Courts, and others, have their several jurisdictions. It follows, that if proceedings are commenced against a man before a court which has no jurisdiction in the matter brought before it, the defendant may answer by alleging that the court has no jurisdiction; which is called pleading to the jurisdiction. When a party is convicted by a court that has no jurisdiction in the matter, the proceedings may be moved into the Court of Queen's Bench by the writ of *Certiorari* and quashed. [CERTIORARI.] Those who have limited jurisdiction are liable to an action, if they assume a jurisdiction which they have not. See Paley on 'Convictions,' 4th edition, p. 400, and 11 & 12 Vict. c. 41, s. 2.

JURISPRUDENCE. The Latin word *prudentia* (contracted from *providentia*) came, by a natural transition, to mean *knowledge* or *understanding*. "Habebat" (says Nepos, 'Life of Cimon,' c. 2) "*magnam prudentiam tum juris civilis tum rei militaris*;" hence persons skilled in the Roman law were called *juris prudentes*, or simply *prudentes*; in the same manner they were called *consulti*, as well as *juris consulti*. (Haubold's 'Lineamenta Instit. Juris Romani,' lib. iv., cap. 5; Hugo, 'Geschichte des Römischen Rechts,' p. 458, ed. xi.) A large part of the Roman law was gradually adopted by the legislature and the judges from the writings of the jurists: the emperors moreover sometimes appointed persons whose opinions (or *responsa*) the *judex* was bound to follow. (D. 1. 2. 2, §§ 5, 7, and 35. 47; 'Inst.' 1. 2. 8.) According to the acceptation of the term *prudens* or *juris prudens* in the Roman law, *juris prudentia* is sometimes limited to the dexterity of a practical lawyer in applying rules of law to individual cases; whence the technical use of the term *jurisprudence* in the French legal language for law founded on judicial decisions; or on the writings of jurists.

By *general jurisprudence* is properly meant the science or philosophy of positive law, as distinguished from *particular jurisprudence*, or the knowledge of the law of a determinate nation. "General jurisprudence, or the philosophy of positive law, is not concerned directly with the science of legislation: it is concerned directly with principles and distinctions which are common to various systems of particular and positive law, and which each of those various systems inevitably involves, let it be worthy of praise or blame, or let it accord or not with an assumed measure or test. General jurisprudence is concerned with law as it necessarily is, rather than with law as it ought to be; with law as it must be, be it good or bad, rather than with law as it must be, if it be good." (Austin's 'Outline of a Course of Lectures on General Jurisprudence,' p. 3.) For example, every system of positive law must involve such notions as sovereignty, legal right, legal duty, legal sanction, civil or criminal injury, the grounds of imputation or legal guilt, and of non-imputation or legal innocence, property, posses-

sion, &c., which therefore belong to the province of general jurisprudence. [LAW; LEGISLATION.]

A systematic treatise on general jurisprudence does not fall within the scope of this Cyclopædia. A detailed, precise, and lucid description of the province of general jurisprudence will be found in Mr. Austin's work on the subject (8vo., London, 1832), and the annexed outline of a course of lectures. Bentham's 'Traité de Législation' also contain much valuable matter relating to this subject. A list of works on general jurisprudence may be seen in Krug's 'Philosophisches Lexicon,' in the article *Rechtslehre*.

JURY (in English law) is a term denoting an assembly of men authorised to inquire into or determine facts, and bound in both cases by an oath to the faithful discharge of their duty. The etymological derivation of the term is obviously from *juro*, to swear, whence we find this institution called in forensic Latin *jurata*, and the persons composing it *jurati*; in French, *les jurés*; and in English, *the jury*. When the object is inquiry only, this tribunal is sometimes called an inquest or inquisition, as in the instance of a grand jury or coroner's inquest; but when facts are to be determined by it for judicial purposes it is always styled a jury. When the trial by jury is spoken of in popular language at the present day, it signifies the determination of facts in the administration of civil or criminal justice by twelve men sworn to decide facts truly according to the evidence produced before them.

Inquiry into facts on behalf of the crown by means of juries was frequent in England long before the trial by jury was commonly used in courts of justice for judicial purposes. Thus we find, immediately after the Conquest, inquisitions *ad quod damnum* (which anciently took place in all grants by the crown, though now of more limited use); inquisitions *post mortem*, which were instituted on the death of the king's tenants, to ascertain of what lands they died seised; inquisitions of lunacy (*de lunatico inquirendo*); and several other inquests, which were called inquests of office, and took place where the crown was concerned in interest: all of these inquiries were made by means of juries of the neighbourhood, who were presumed to be necessarily conversant with the facts. So in England also in the reign of John, when the lands of the Normans were seised into the hands of the king, inquisitions by jury were executed in each county to ascertain their value and incidents. (Hardy's 'Rotuli Normanniæ,' vol. i., p. 122.)

Besides these juries of inquiry (*inquisitoria jurata*), there were accusatory juries (*jurata delatoria*), who presented offences committed within their district or ward, hundred, or county, to the king or his commissioned justices. These inquests were immediately connected with the administration of justice, their duty being to charge offenders, who, upon such accusation, were put upon their trial before judges, and were afterwards condemned or "delivered" by them according to the result of the trial. Though the character, incidents, and duties of these accusatory juries in early times are involved in much obscurity, there is little doubt that they formed the origin of our present grand juries.

The number of persons composing juries of inquiry and accusatory juries was arbitrary, and might consist of more or occasionally of fewer than twelve men.

The third species of jury is the institution by which disputed facts are to be decided for judicial purposes in the administration of civil or criminal justice, and which is in modern times familiar to us under the denomination of *trial by jury*. Juries of this description have been considered to exercise the same functions as the *dicastæ* (*δικασταί*) of the Athenians and the *judices* of the Romans, and our trial by jury has accordingly sometimes been considered to have been derived immediately from Rome, and ultimately from Greece. The precise time at which this species of trial originated in England has been the subject of much animated discussion; and in particular the question whether it was known to the Anglo-Saxons, or was introduced by the Conqueror, has been warmly debated. Coke and Spelman, among earlier legal antiquaries, and, in later times, Nicholson (Preface to Wilkins's 'Anglo-Saxon Laws'), Blackstone, and Turner ('Anglo-Saxons,' vol. iv., b. xi., c. 9), maintain with much confidence the existence of this institution before the Conquest. On the other hand, Hickes ('Dissert. Epist.,' p. 34), Reeves ('History of the English Law,' vol. i., p. 24), and several other learned writers, contend that it was introduced by the Conqueror, or at least that it was derived from the Normans, and was not of Anglo-Saxon origin. The latter opinion is adopted by Sir Francis Palgrave, 'History of the English Commonwealth,' v. i., p. 243.

Without entering minutely into this controversy, it may be stated that the traces of the trial by jury, in the form in which it existed for several centuries after the Conquest, are more distinctly discernible in the ancient customs of Normandy than in the few and scanty fragments of Anglo-Saxon laws which have descended to our time. The trial by 12 compurgators, which was of canonical origin and was known to the Anglo-Saxons and also to many foreign nations, resembled the trial by jury only in the number of persons sworn; and no conclusion can be drawn from this circumstance, as 12 was not only the common number throughout Europe for canonical and other purgations, but was the favourite number in every branch of the polity and jurisprudence of the Gothic nations. (Spelman, 'Gloss.,' tit. 'Jurata.') Besides this, the trial by compurgators under the name of Wager of Law continued to be the law of England till abolished, in 1833, and is treated by all writers and noticed in judicial

records ever since the Conquest as a totally different institution from the trial by jury. The trial *per sectatores* or *per pares* in the county court, which has sometimes been confounded with the trial by jury, was in truth a totally different tribunal. The sectatores or pares were, together with the sheriff or other president, judges of the court; and it appears to have been the common course with the Gothic nations that twelve assessors should be present with the king or judge to decide judicial controversies. (Du Cange, 'Gloss., ad vocem 'Pares.')

The *pares curiæ* resembled permanent assessors of the court, like the *scabini* mentioned in the early laws of France and Italy, much more nearly than sworn jurors indiscriminately selected, and performing a subordinate part to the judge. On the other hand, the incidents of the mode of trial prevalent in Normandy long before the Conquest correspond in a striking manner with those of our trial by jury as it existed for centuries afterwards. Thus in Normandy offenders were convicted or absolved by an inquest of good and lawful men summoned from the neighbourhood where the offence was surmised to have been committed. The law required that those were to be selected to serve on such inquest who were best informed of the truth of the matter; and friends, enemies, and near relatives of the accused were to be excluded. So also in the Norman Writ of Right, those were to be sworn as recognitors who were born and had ever dwelt in the neighbourhood where the land in question lay, in order that it might be believed that they knew of the truth of the matter, and would speak the truth respecting it. ('Grand Coustumier,' cap. 68, 69, 103.) These incidents, though unlike our present mode of trial (which, as will presently be shown, has entirely altered its character within the last four centuries), are nearly identical with the trial by jury as it is described first by Glanville and afterwards by Bracton, and correspond almost verbally with the form of the jury process, which has continued the same from very early times to the present day, by which the sheriff is commanded to return "good and lawful men of the neighbourhood, by whom the truth of the matter may be better known, and who are not akin to either party, to recognise upon their oaths," &c. On the other hand (as Madox remarks, in his 'History of the Exchequer,' p. 122), "if we compare the laws of the Anglo-Saxon kings with the forms of law process collected by Glanville, they are as different from one another as the laws of two several nations."

Though there are some traces of the trial by jury in the four reigns which immediately succeeded the Norman Conquest, it was not till a century afterwards, in the reign of Henry II., that this institution became fully established and was reduced to a regular system. Its introduction into frequent use at this period was probably owing to the law or ordinance for the trial by assize in pleas of land or real actions, made by Henry II. This law has not come down to our times, but it is fully described by Glanville (lib. ii. cap. 7), and the greater part of the treatise of that writer is occupied by an account of the practical machinery of the trial by twelve men, which he warmly eulogises and represents as having been introduced in opposition to the unsatisfactory mode of trial by battle or duel. In the reign of Henry II. it appears also that a jury was sometimes used in matters of a criminal nature—the proceeding in such cases being noticed as an inquiry *per juratam patriæ vel vicinæ*, or *per juramentum legalium hominum*. Thus in the 'Constitutions of Clarendon,' enacted in 1164, it is directed that "if no person appeared to accuse an offender before the archdeacon, the sheriff should, if requested to do so by the bishop, cause twelve lawful men of the neighbourhood or of the township to be sworn, who might declare the truth according to their conscience." These however were probably accusatory juries, similar to our grand inquests, and not juries employed for the actual trial or "deliverance" of criminals, which do not seem to have been commonly used until a later period.

The law of Henry II. introduced the trial by assize or jury in real actions as a mode of deciding facts which the subject might claim as a matter of right. Glanville calls it "a certain royal benefit conferred upon the people by the clemency of the sovereign with the advice of the nobility." Accordingly we find in the 'Rotuli Curie Regis' in the time of Richard I. and John, many instances of trials by jury being claimed by parties, though it appears from these curious records that at this period the trial by battle was still in frequent use. In the reign of John we first begin to trace the use of juries for the trial of criminal accusations. At first it seems to have been procured by the accused as a special favour from the crown, a fine, or some gift or consideration, being paid in order to purchase the privilege of a trial by a jury. Several instances of this kind will be found collected in the notes and illustrations to Palgrave's 'Commonwealth of England,' vol. ii., p. 186. The payment of a fine took place also not unfrequently in civil cases, where any variation from the regular course was required; see 'Rotuli Curie Regis,' vol. i., pp. 354, 375; vol. ii., pp. 72, 92, 97, 101, 114. It is quite clear, however, from Bracton and Fleta, that at the end of the 13th century the trial by jury in criminal cases had become usual, the form of the proceedings being given by them in detail. (Bracton, p. 143.) Introduced originally as a matter of favour and indulgence, it gained ground with advancing civilisation, gradually superseding the more ancient and barbarous customs of battle, ordeal, and wager of law, until at length it became, both in civil and criminal cases, the ordinary mode of determining facts for judicial purposes.

It is right to notice the popular and remarkable error that the

stipulation for the *judicium parium* in Magna Charta referred to the trial by jury. Sir Edward Coke in his commentary upon Magna Charta expressly distinguishes between the trial by peers and the trial by jury (2nd Inst. 48-9); but Blackstone says, "The trial by jury is that trial by the peers of every Englishman, which, as the grand bulwark of his liberties, is secured to him by the Great Charter." ('Commentaries,' vol. iv., p. 349.) This is confounding two distinct modes of trial. The *judicium parium* was the feudal mode of trial, where the *pares* or *convassalli ejusdem domini* sat as judges or assessors with the lord of the fee to decide controversies arising between individual *pares*. It was a phrase perfectly understood at the period of Magna Charta, and the mode of trial had been in use long before in France and all parts of Europe where feuds prevailed. (Du Cange, 'Gloss., ad vocem 'Pares.')

It was essentially different from the trial by jury, which could never be accurately called *judicium parium*. We read frequently in the records of those times (and even in Magna Charta itself), of *juratores*, of *verdictum* or *juramentum legalium hominum*, and *jurata vicinæ* or *patriæ*, all of which expressions refer to a jury; but not a single instance can be found in any charter, or in any ancient treatise or judicial record, in which the jury are called *pares*, or their verdict *judicium*. (Reeves's 'History of the Law,' vol. i., p. 249.) In the records of the 'Curia Regis' in the first year of John's reign, among numerous entries of *Ponit se super juratam vicinæ* or *patriæ*, are also entries of *Ponit se super pares suos de eodem feodo*, plainly indicating a distinction between the two modes of trial. ('Rotuli Curie Regis,' vol. ii., p. 90.)

Until about the reign of Henry VI. the trial by jury was to all intents and purposes a trial by witnesses. The present form of the jurors' oath is that they shall "give a true verdict, according to the evidence." At what precise time this form was introduced is uncertain; but for several centuries after the Conquest, the jurors both in civil and criminal cases were sworn merely to *speake the truth*. (Glanville, lib. ii., cap. 17; Bracton, lib. iii., cap. 22; lib. iv., p. 287, 291; Britton, p. 135.) Hence their decision was accurately termed *verdictum*, or verdict; whereas the phrase "true verdict" in the modern oath is not only a pleonasm, but is etymologically incorrect, and misdescribes the office of a juror at the present day. Many other incidents of the trial by jury, as recorded in ancient treatises, conclusively show that the jury were merely witnesses. They were brought from the neighbourhood where the disputed fact was suggested to have occurred, because, as the form of the jury process says, they were the persons "by whom the truth of the matter might be better known;" no doubt upon the principle that *Vicini vicinorum presumuntur scire*. Again, if the jurors returned by the sheriff in the first instance declared in open court that they knew nothing of the matter in question, others were summoned who were better acquainted with it. (Glanville, lib. ii., cap. 17.) They might be excepted against by the parties upon the same grounds as witnesses in the Court Christian. They were punished for perjury if they gave a wilful false verdict; and for *crassa ignorantia* if they declared a falsehood or hesitated about their verdict upon a matter of notoriety, which all of the country (*de patriâ*) might and ought to have known. (Bracton, p. 290.) And ancient authors solemnly admonish judges to "take good heed in inquisitions touching life and limb, that they diligently examine the jurors from what source they obtain their knowledge, lest peradventure by their negligence in this respect Barabbas should be released and Jesus be crucified." (Bracton, lib. iii. cap. 21; Fleta, lib. i., cap. 34.) It is also remarkable, as one of the numerous circumstances which show the character of the jury in the earlier periods of the history of the institution, that though all other kinds of murder might be tried by a jury, murder by poison was excepted, "because," say the ancient writers, "the crime is so secret that it cannot be the subject of knowledge by the country." (Bracton, lib. iii., cap. 18; Fleta, lib. i., cap. 31.)

The original principle and character of the trial by jury in criminal cases in Scotland appear to have been the same as in England. The following extract is taken from a curious paper delivered to the Speaker of the House of Commons, and recorded on the Journals at the date 4th June, 1607. ('Comm. Journ.,' vol. i., p. 378.) "In Scotland criminal cases are not governed by the civil law; but *ordanes* (a word printed by mistake for some other) and juries pass upon life and death, very near according to the law here (in England). Which jury being chosen out of the Four Halfs about (as the Scottish law terms it), which is to say, out of all places round about that are nearest to that part where the fact was committed, the law doth presume that the jury may the better discern the truth of the fact by their own knowledge; and therefore they are not bound to examine any witnesses, except out of their own disposition they shall please to examine them in favour of the party pursuer; which is likewise very seldom or almost never used. It is of truth that the judge may either privately beforehand examine such witnesses as either the party pursuer will offer unto him, or such others as in his own judgment he thinks may best inform him of the truth; and then when the jury is publicly called and admitted, he will cause these depositions to be produced and read; and likewise if the party pursuer desire any witness there present to be examined, he will publicly do it in presence of the jury and both parties." It will be observed, that the mode of commencing the introduction of evidence to juries as described in this

document bears a strong resemblance to the growth of the proceeding in England.

The earliest traces of the examination of witnesses or of evidence being laid before juries in England, which formed the commencement of a total change in their character, occur in the reign of Henry VI. The change was not effected suddenly, or by any particular act of parliament, but was introduced by slow degrees as population increased, and the habits and manners of society underwent alteration; and though distinctly discernible in the reign of Henry VI., was not completely effected before the times of Edward VI. and Mary. Fortescue, in the 26th chapter of his work 'De Laudibus Legum Angliæ,' written at the end of the reign of Henry VI., and about the year 1470, expressly mentions that witnesses were examined and sworn before the jury; but he calls the jury indiscriminately *testes* and *juratores*, and makes frequent allusions to their character as witnesses. Shortly after Fortescue's time—namely, in the year 1498—there is a reported case between the Bishop of Norwich and the Earl of Kent ('Year Book,' 14 Henry VII.), in which a jury had been separated by a tempest "while the parties were showing their evidence;" and one question raised for the opinion of the court was, whether, when the jury came together again, they were competent to proceed with the case and to give a verdict. The objection pressed was that the jury had separated before the evidence was given; to which it was answered that "the giving the evidence was wholly immaterial, and made the matter neither better nor worse; that evidence was only given in order to inform the consciences of the jury respecting the rights of the parties; but that if neither party chose to give evidence, still the jury would be bound to deliver a verdict."

About the same period,—that is, in the reign of Henry VII.,—it appears from records printed in Rastell's Entries, that demurrers to evidence were an acknowledged form of proceeding, which shows that at that time evidence of some kind was given, and consequently that the character of the jury had been in some degree changed from that of *witnesses* to that of *judges* of facts upon testimony. The proofs mentioned in these records are called *evidentia*; and it is most probable that at first the only evidence given consisted of deeds, writings, and of depositions of absent witnesses taken before the justices of the peace or other magistrates, and that oral testimony was not common until a later period. The entire absence of all mention of evidence or witnesses, as contradistinguished from jurors, in treatises, reports, records, or statutes, previously to the 16th century, strongly corroborates the fact of the early character of the trial by jury. There is no trace of any rules of evidence, nor of any positive law compelling the attendance of witnesses, or punishing them for false testimony or non-attendance, nor of the existence of any process against them before the stat. 5 Eliz. c. 9 (1562). In the case of *Summers v. Mosely*, reported in 2 Crompton and Meeson, p. 485, Mr. Baron Bayley says that he had been unable to find any precedents of the common *Subpoena ad testificandum* of an earlier date than the reign of Elizabeth, and expresses a conjecture that this process may have originated with the above-mentioned statute. The *Subpoena ad testificandum* does not appear in the registers of Writs and Processes until the reign of James I. (West's 'Symboleography.') Witnesses were examined orally upon the trial of Sir Thomas More, in the reign of Henry VIII.; but the reported state trials in the reigns of Edward VI. and Mary show that the practice in that respect was then by no means settled. In the reign of Elizabeth, however, there is abundant proof, from Sir Thomas Smith's 'Commonwealth of England,' and other authorities, that oral testimony was used without reserve (except in state prosecutions) both in civil and criminal trials; and consequently it cannot be doubted that about the middle of the 16th century the trial by jury had fully assumed the character in which we are now familiar with it—namely, an institution deciding facts for judicial purposes by means of testimony or evidence produced before the jury.

This view of the original character and office of the jury seems to account for the practice of fining or otherwise punishing juries by the court when they gave an unsatisfactory verdict; a practice which was partially continued, though not without remonstrance by legal authorities, after the nature of the institution had been changed. If juries, who were merely witnesses sent for to inform the court of facts which they were presumed certainly to know, returned a wilfully false verdict, they were guilty of a contempt of justice, and might properly be punished; but when their character was changed, and their verdict depended not on their own knowledge of the facts, but upon the impressions produced on their minds by the evidence, such a course of summary punishment became intolerable injustice; and though occasionally practised in the 16th century, was declared to be illegal soon after the Restoration by the celebrated judgment in *Bushell's case*, reported in Vaughan's Reports, p. 135.

The juries now in use in England in the ordinary courts of justice are grand juries, petty or common juries, and special juries. Grand juries are exclusively incident to courts of criminal jurisdiction; their office is to examine into charges of crimes brought to them at assizes or sessions, and if satisfied that they are true, or at least that they deserve more particular examination, to return a bill of indictment against the accused, upon which he is afterwards tried by the petty jury. A grand jury must consist of twelve at the least. In practice a greater number usually serve, but twelve must concur in finding

every indictment. No further qualification is required for grand jurors (except in the case of grand jurors at the sessions of the peace, provided for by the recent Jury Act) than that they should be freeholders, though to what amount is uncertain; or freemen, lawful liege subjects, and not aliens or outlaws. (Hawkins's 'Pleas of the Crown,' chap. 25, sect. 16.)

Until the end of the 13th century the only qualification required for petty or common juries, for the trial of issues in criminal or civil courts, was that they should be "free and lawful men;" *freemen*, as holding by free services or free burgesses in towns; and *lawful men*, that is, persons not outlawed, aliens, or minors, but entitled to the full privileges of the law of England. By the statute of Westminster 2, passed in the 13th year of Edward I. (1296), it was enacted that no man should be put on juries who had not some freehold of the value of 20s. a year within the county, or 40s. without it; and this qualification was raised to 40s. in counties by the statute 21 Edward I. The object of these statutes was to protect poor persons from being oppressed and injured by being summoned on juries, and also to obviate the evil of the non-attendance of jurors, which frequently occurred from their inability to leave their agricultural or handicraft occupations. The stat. 2 Henry V. however was expressly intended to secure the intelligence and responsibility of jurors by requiring a property qualification. With this view it enacted that no person should be a juror in capital trials, nor in any real actions, or personal actions where the debt or damages declared for amounted to 40 marks, unless he had lands of the yearly value of 40s.; and if he had not this qualification he might be challenged by either party. This continued to be the qualification of common jurors until the passing of the statute 6 George IV., c. 50, which repealed all former statutes upon this subject, and entirely remodelled the law respecting juries. By this statute "every man (with certain specified exceptions) between the ages of twenty-one years and sixty years who has within the county in which he resides 10l. a year in freehold lands or rents, or 20l. a year in leaseholds for unexpired terms of at least twenty-one years, or who, being a householder, is rated to the poor-rate in Middlesex on a value of not less than of 30l., and in any other county of not less than 20l., or who occupies a house containing not less than fifteen windows, is qualified and liable to serve on juries in the superior courts at Westminster and the courts of the counties palatine for the trial of issues to be tried in the county where he resides, and also to serve on grand juries at the sessions of the peace, and on petty juries, for the trial of issues triable at such sessions in the county in which he resides." The exceptions are:—peers, judges of the superior courts, clergymen, Roman Catholic priests, dissenting ministers following no secular employment but that of a schoolmaster, serjeants and barristers at law, and doctors and advocates of the civil law actually practising; attorneys, solicitors, and proctors actually practising; officers of courts actually exercising the duties of their respective offices; coroners, gaolers, and keepers of houses of correction; members and licentiates of the college of physicians actually practising; surgeons, being members of one of the royal colleges of surgeons in London, Edinburgh, or Dublin, and actually practising; apothecaries certificated by the Apothecaries' Company and actually practising; officers in her majesty's navy or army on full pay; pilots licensed by the Trinity House; masters of vessels in the buoy and light service; pilots licensed by the lord-warden of the cinque-ports, or under any act of parliament or charter; household servants of the sovereign; officers of customs and excise; sheriffs' officers, high constables, and parish clerks.

Lists of all persons qualified to be jurors are made out by the churchwardens and overseers of each parish, and fixed on the church door for the first three Sundays in September in each year; these are afterwards allowed at a petty sessions and then delivered to the high constable, who returns them to the next quarter-sessions for the county. The clerk of the peace then arranges the lists in a book, which is called the 'Jurors' Book' for the ensuing year, and afterwards delivers it to the sheriff. From this book the names of the jurors are returned in panels to the different courts.

Special juries are composed of such persons as are described in the 'Jurors' Book' as esquires, and persons of higher degree, or as bankers or merchants; and it is the duty of the sheriff to make a distinct list of such persons, which is called the 'Special Jurors' List.' When a special jury is ordered by any of the courts, which must always be the result of a special application of one of the parties, 48 names are taken by ballot from this list in the manner particularly described in the statute, which are afterwards reduced to 24 by means of each party striking out 12; and the first 12 of these 24 who answer to their names in court are the special jury for the trial of the cause.

The legitimate mode of objecting to a jury by the parties is by challenge, though in modern practice this course is seldom resorted to, having yielded to the more convenient usage of privately suggesting the objection to the officer who calls the jury in court; upon which the name objected to is passed over as a matter of course without discussion. This practice, though a far less troublesome and obnoxious mode of effecting the object of obtaining a jury indifferent between the parties than a formal challenge, is, strictly speaking, irregular, and being considered to take place by consent, and as a matter of favour, cannot be insisted upon as a right. Challenges are of two kinds: challenges to the *array*, and challenges to the *polls*. The challenge to the array is

an objection to the whole panel or list of jurors returned for some partiality or default in the sheriff or the under-sheriff by whom it has been *arrayed*. Challenges to the polls are objections to particular jurors, either on the ground of incompetency (as if they be aliens, or of insufficient qualification within the provisions of the Jury Act, 6 Geo. IV., cap. 50), or of bias or partiality, or of infamy, as having been convicted of some crime which the law deems infamous. Upon these challenges the cause of objection must in each case be expressly shown to the court; but in trials for capital offences the accused is entitled to challenge *peremptorily* (that is, without giving any reason) thirty-five jurors. The king, however, as nominal prosecutor, has no right of peremptory challenge, though he is not compelled to show his cause of challenge until the panel is gone through, and unless a full jury cannot be formed without the person objected to.

The trial by jury, originally introduced into the law of France in criminal cases by the National Assembly, was retained in the French code. An account of the proceeding and of the qualifications and formation of the jury will be found in the 'Code d'Instruction Criminelle,' livre ii., tit. 2, chap. iv. and v. It has often been remarked as a singular fact, that the institution which in England has been highly prized as a security to the subject against the crown, should have been preserved in France by a despotic monarch, in the zenith of his power, and certainly not disposed to enlarge popular authority. The advantage of the trial by jury has been frequently the subject of debate among German and French jurists, and in particular the propriety of its introduction has been discussed in the various commissions issued with a view to reforming the laws of several of the German States.

Anciently in Scotland all offences were tried by juries; at present all prosecutions of a higher nature must proceed by an assize or jury of 15 men, who determine their verdict by a majority of voices. (Erskine's 'Principles of the Law of Scotland,' book iv. tit. 4.) In the course of many attempted improvements of the Court of Session, several efforts have been made to introduce the trial by jury into civil proceedings in Scotland; but great and general opposition has been made to it by the courts and the legal profession in Edinburgh. It cannot be said to have been fairly tried as yet, for no judges have been trained to its use, and no generation has had opportunity to learn how to act as jurymen. Whether the people of Scotland shall ever obtain the advantages of our English trial by jury, it seems difficult to say. Recent legislation on the subject, and recent observations in the House of Lords, have demonstrated that as an instrument in the administration of civil justice, trial by jury is not yet practicable in Scotland.

JUSTICE CLERK OF SCOTLAND, is now the second president of the Court of Justiciary in Scotland, being originally the clerk of court of the chief justice, or Lord Justice General of Scotland.

At the institution of the Court of Session in 1532, the justice clerk was made one of the judges. This will not surprise us when we consider the constitution of that court. It was essentially an ecclesiastical tribunal, and, agreeably to the practice of such, deliberated in secret with shut doors. It was necessary therefore for the security of the crown that some of the crown officers should be continually present. The justice clerk was one of these: he was public prosecutor on behalf of the crown. The king's treasurer was another; and accordingly both these were lords of session.

A further rise of official dignity took place: for it having become usual to appoint certain lords of session as assessors or assistant judges to the lord justice-general, the justice clerk began in the early part of the 17th century to be appointed to that duty; and about the middle of the same century he had acquired the style of "lord justice clerk." In ten years afterwards the privy council declared the justice clerk a constituent part of the justice court; and in 1672, he was made president of the Court of Justiciary, to preside in absence of the justice-general. His rise in the Court of Session followed; for in 1766, when Miller, afterwards Sir Thomas Miller of Glenlee, took his seat on the bench, it was, by desire of the court, on the right of the lord president; to which latter office he himself afterwards rose, being the first justice clerk so promoted. And in 1811, when the Court of Session, was, by 48 Geo. III., c. 151, divided into two chambers, the lord justice clerk was made *ex officio* president of the second division.

With respect to the *justice clerk depute*, that officer was long so termed; but when the justice clerk acquired the style of lord, and became a constituent part of the Court of Justiciary, his *depute* came to be termed "the principal clerk of justiciary," and this becoming a sinecure, he got himself a "depute" about the middle of last century, and the second depute in due course an "assistant;" all of whom, except the first sinecure office, the holder of which was a few years ago bought off by government, continue to this day, and are in the gift of the lord justice clerk.

Besides these there are three other justice clerk deputies, and his appointees. They are commonly called the "circuit clerks," being his deputies to the three circuits of the Court of Justiciary. They had their origin in the act 1587, c. 82, which directed such circuits to be made, in place of the former practice of the justiciar passing through the realm from shire to shire successively.

JUSTICE, LORDS, OF APPEAL IN CHANCERY. These judges, who are two in number, were created by the statute 14 & 15 Vict. c. 83, to assist the Lord Chancellor in the determination of appeals from

the Master of the Rolls and Vice-Chancellors. They possess besides an original jurisdiction, so that when all the appeals are disposed of, they may hear causes in the first instance. The Lord Chancellor may sit with them, or separately, as a Court of Appeal. In Bankruptcy the Lords Justices constitute the Court of Appeal; in matters of lunacy they have, under the sign manual, the same authority as the Lord Chancellor.

JUSTICES, LORDS. Our kings have been, ever since the Conquest, in the habit of appointing, as occasion required, one or more persons to act for a time as their substitutes in the supreme government either of the whole kingdom or of a part of it. When William I. returned to Normandy, the year after the Conquest, he left his half-brother Odo, Bishop of Bayeux, and William Fitzherbert, to be *Custodes Regni*, or guardians of the realm, during his absence; and similar appointments were very frequent under the early Norman and Plantagenet kings. Down to the present time, indeed, similar officers have been appointed under various names, and with more or less extensive powers according to circumstances. Protector, lieutenant, or locum tenens, and regent, have been among the other names by which they have been known. Regents and councils of regency, during the nonage of the king or queen, have been sometimes named by the preceding possessor of the crown; but in modern times such arrangements have been usually made by statute. Coke remarks (4 'Inst.' 58) that the methods of appointing a guardian or regent have been so various, that "the surest way is to have him made by authority of the great council in parliament."

The most familiar case of the appointment by the crown of a representative to exercise the supreme executive power, not in a colony or dependency, is that of the appointment of the lord-lieutenant of Ireland, or of a council of government composed of lords justices.

The governor-general of Ireland under the crown has been styled at different times *custos* (keeper or guardian), *justiciary*, *warden*, *procurator*, *seneschal*, *constable*, *justice*, *deputy*, and *lieutenant*. Viceroy is a name of modern introduction. Formerly, upon the avoidance of the office by death or otherwise, the privy council there was authorised to elect a successor, with the restriction that he should be an Englishman and no spiritual person, who held office till the king appointed another. The ancient powers of this officer were almost regal; he performed every act of government without any previous communication with England; and when he left the country he even appointed his own deputy. From the Revolution, however, till the reign of George III., the lord-lieutenant resided very little in Ireland; in several instances the person appointed to the office never went over; in other cases he went over once in two years to hold the session of parliament; and the government was very often left in the hands of lords justices, without a lord-lieutenant at all. In modern times the appointment of lords justices for Ireland has only taken place on the occasional absences of the lord-lieutenant; and the lords justices have usually been the lord primate, the lord chancellor, and the commander of the forces.

In England lords justices and regents have been repeatedly appointed since the Revolution, on occasion of the king going abroad; and the appointment has usually, if not always, been made by letters patent, in the same manner as the lords-lieutenant or lords justices of Ireland have always been appointed. In some cases, however, the aid of parliament has been called in for certain purposes. When King William went over to Ireland, in 1689, he of his own authority appointed the administration of the government to be in the hands of the queen during his absence out of the kingdom, by declaration at the council-table; and at the same time an act was passed, 1 and 2 W. & M., s. 2, in the preamble of which his majesty's pleasure was recited, and it was enacted, that whensoever his majesty should be absent, it should be lawful for the queen to administer the regal power and government. This act was considered to be necessary, in consequence of the peculiar circumstances in which the queen was placed by the Act of Settlement, which had declared that the entire, perfect, and full exercise of the regal power and government should be only in and executed by his majesty in the names of both their majesties during their joint lives. It was at the same time provided, "That as often as his majesty shall return into this kingdom of England, the sole administration of the regal power and government thereof shall be in his majesty only, as if this act had never been made." After the queen's death lords justices were repeatedly appointed by the king.

One of the provisions of the statute of 12 & 13 W. III. (passed in 1700) for settling the succession in the House of Hanover, was, "That no person who shall hereafter come to the possession of this crown shall go out of the dominions of England, Scotland, or Ireland, without consent of parliament." This clause, however, was repealed in 1716, by 1 George I., stat. 2, c. 51. The repealing act was passed to gratify the king, whose "impatience to visit his German dominions," says Coxe in his 'Life of Walpole,' i. 77, "now became so great as totally to overcome every restraint of prudence and suggestion of propriety, and imperiously to demand indulgence." "The ministry," continues the historian, "were considerably embarrassed on this occasion, and drew up a strong remonstrance representing the inconvenience which would result from the projected journey. The remonstrance, however, not only failed of success, but so far exasperated the king, that he declared he would not endure a longer confinement in this kingdom."

It was thought more respectful to his majesty to obtain a repeal of the restraining clause at once, than to ask parliament merely for the leave of absence; and the bill passed through all its stages in both Houses without a dissenting voice, the Tories being favourably disposed to the principle, and the Whigs averse or frightened to offend the king. His majesty, who was at variance with his eldest son, now interposed another difficulty, refusing to intrust the government during his absence to the prince, without joining other persons with him in the commission, and also limiting his authority by the most rigorous restrictions. Upon this point, however, he yielded at last to the representations of the ministers, who concluded a long exposition of reasons against his leaving the kingdom at all at that crisis by stating that, "upon a careful perusal of the precedents, finding no instance of persons being joined in commission with the Prince of Wales" in the appointment of a regency, "and few, if any, restrictions upon such commissions," they were of opinion that the constant tenor of ancient practice could not conveniently be receded from. (Coxe, ii. 51-54.) Upon this the king submitted to give the prince the sole direction of affairs; "yet," says Coxe, quoting from the work called 'The Political State of Great Britain,' "he appointed him *Guardian of the Realm and Lieutenant*, an office unknown in England since it was enjoyed by Edward the Black Prince." In point of fact the title given to the prince in the original Latin commission was *Custos Regni nostri et Locum tenens*, which were the same words that had been commonly used in all such commissions down to the reign of Henry VIII., with this difference only, that one of the two titles (more frequently *Custos Regni*) was alone employed. The earliest use of the term *regent* appears to have been in the commission from Henry VIII. to Queen Katherine Parr, when he went over to Boulogne in 1544, in which she is styled *Rectrix et Gubernatrix Regni nostri*. Queen Mary, the wife of William III., whose case is the next that occurs, seems, as already stated, to have had no commission; and, being queen regnant in her own right, she was not even popularly styled regent.

When George I. went abroad, in May, 1719, he intrusted the government during his absence not to a regent, or any single person, but to thirteen lords justices, composed of the Archbishop of Canterbury and the principal officers of state. The commission begins by reciting that his majesty had "determined, for divers weighty reasons, speedily to go in person beyond the seas." The persons commissioned are appointed to be "our guardians and justices (*Justiciarii* must be the Latin term) of our said kingdom of Great Britain, and our lieutenants in the same, during our absence out of our said kingdom, or till further signification of our pleasure;" and they were authorised, four being made a quorum, "to execute the office and place of guardians, &c., and to order, do, and perform all and every act and acts of government and administration of government, and all other matters and things whatsoever, which, by virtue or reason of the aforesaid office or place, have been usual, or may be lawfully ordered, done, or performed." Power is afterwards specially given to keep the peace, to cause the laws and customs of the kingdom to be observed by all, to punish criminals, to hold the parliament then existing, to summon and hold other parliaments, to summon and hold the Privy Council; with the advice of the Privy Council, to issue proclamations, "and to do and perform all other things which have been usually done, or may be done, by us, by or with the advice of the same;" to appoint ambassadors, to make and conclude treaties; to confer, grant, and present to all benefices, to issue commands under the privy seal for and concerning the collection, levying, and disposal of the revenue; to command the army; to execute martial law in time of war, if that should happen; to command and employ the naval forces of the kingdom; to appoint to and discharge from all offices at the disposal of the crown; to grant pardons for high treason and all other crimes and offences; and finally, to do all these things in Ireland as well as in Great Britain.

The enumeration of the powers granted by this commission is probably the most authentic compendium that has been published of the functions of government ordinarily exercised by the crown. It does not, however, profess to be an enumeration of all the powers resident in the crown; and it may be observed, that besides, perhaps, some appertaining to the office of supreme head of the church, the power of creating peers and conferring honour is not made over to the lords justices. That is a power which, we believe, never has been delegated, or attempted to be delegated, if we except only the case of the patent granted by Charles I., in 1644, to Lord Herbert (better known as the Earl of Glamorgan), which, after the Restoration, he was compelled to resign by the interference of the House of Lords.

The Lords Justices are further required, in the execution of their powers, punctually to observe his majesty's pleasure, as it might be from time to time expressed in instructions signed by the royal hand; and the commission was accompanied by a set of instructions, twenty-one in number, the most important things directed in which are, that no livings or benefices in the gift of the crown which may become vacant shall be disposed of without his majesty's directions; that no orders or directions concerning the disposition of money shall be given before his majesty's pleasure shall have been signified thereupon; and that there must be no exercise of the power dissolving the parliament, or calling a new one, without special signification of the royal pleasure. The same restriction is put upon the exercise of the power of pardoning, and some of the other powers. In case however they should hold

it necessary or expedient for the public service, the Lords Justices are authorised to fill offices immediately, and also to reprieve criminals; and they are permitted to continue the existing parliament by short prorogations, until they should be otherwise directed under the royal sign manual, and to summon the privy council to meet as often as they shall see occasion.

The government was in the same manner intrusted by George I. to lords justices when he again went abroad in 1720, 1723, 1725, 1727.

Queen Caroline, wife of George II., was so long as she lived always intrusted with the administration of the government when that sovereign went abroad. The 2 Geo. II. chap. 27, was passed in 1729, "To enable her majesty to be regent of this kingdom, during his majesty's absence, without taking the oaths;" on the 15th of May thereafter, according to Salmon's 'Chronological Historian,' a commission passed the great seal constituting her guardian and lieutenant of the kingdom during the king's absence; and the same authority states her to have been appointed guardian in 1732, and regent on the two other occasions. A patent, with the like powers as that issued to the Prince of Wales in 1716, passed in 1732, appointing Queen Caroline guardian and lieutenant of the kingdom in the king's absence. Most probably all the four appointments were made in the same manner and in the same terms. After the death of Queen Caroline, the government was always left during the reign of George II. in the hands of lords justices when the king went abroad; the commissions and the accompanying instructions being on all occasions nearly the same with those issued in 1719.

George III. during his long reign never left England. When George IV. went to Hanover, in September, 1821, nineteen guardians and lords justices were appointed, the Duke of York being the first. "One good effect arose from their appointment, that the lords justices during his (the king's) absence signed an immense number of military commissions and other documents, which had been accumulating since his accession to the throne." ('Morning Chronicle,' Aug. 11, 1845.) The writer of the newspaper article here quoted contends that "the royal authority of an English monarch cannot be personally exercised in a foreign country." "We take it," he adds, "to be quite clear, that a patent sealed with the great seal in a foreign country would be void. To guard against any such irregularity, the law requires that the patent shall state the place where it is signed and sealed as *apud Westmonasterium*."

Nevertheless, no provision such as had been customary on such occasions has been made for the exercise of the royal authority when her present majesty has temporarily left the kingdom. On one occasion the subject was (for what object does not appear) brought forward in the House of Lords by Lord Campbell, who, after stating at some length the course which he maintained had been uniformly taken down to the year 1843, asked if it was the intention that lords justices should be now appointed? The lord chancellor replied that the government had no such intention. "On the occasion of her majesty visiting the King of the French," his lordship is reported to have said, "the then law officers of the crown, the present lord chief baron and the late Sir William Follett, had been consulted. . . . And after mature deliberation, these learned persons gave it as their decided opinion that it was not at all necessary in point of law that such an appointment should take place. . . . In the present instance, also, the law officers of the crown had been consulted as to whether it was necessary in point of law for her majesty to appoint a regency during her absence, and their reply was that it was in no degree necessary; an opinion in which he entirely concurred."

It ought to be mentioned that the seven persons appointed in 1705 by the 4 & 5 Anne, c. 8, and again in 1707, by the 6 Anne, c. 7, to administer the government along with other persons whom the new king or queen should have named, in case of his or her absence at the time from the kingdom, are styled lords justices in the act, although called regents by Burnet, and in the common accounts. These lords justices (twenty-six in all) who actually came into office on the death of Queen Anne, 1st August, 1714, and continued till the arrival of the king on the 18th of September, enjoyed more extensive powers than any others that have been appointed, at least in modern times. They were authorised to execute all powers of government, in as full and ample manner as the next successor could use or execute the same if she or he were present in person within this kingdom of Great Britain, until such successor should arrive, or otherwise determine their authority. The only restrictions laid upon them were, that they were not, without direction from the "queen or king," to dissolve parliament; and that they would subject themselves to the pains of high treason if they gave the royal assent to any bill or bills for repealing or altering the Act of Uniformity, or the Act for the Establishment and Maintenance of the Presbyterian Church Government in Scotland.

The most important of the facts we have stated have been derived from the report of the committee appointed by the House of Commons in 1788, "to examine and report precedents of such proceedings as may have been had in the case of the personal exercise of the royal authority being prevented or interrupted by infancy, sickness, infirmity, or otherwise," which is printed in the Journals of the House, vol. xlv., pp. 11-42. And some particulars may be gleaned from the accounts of the proceedings in the two Houses of Parliament on occasion of the king's illness in 1788, as reported in the 'Parliamentary History,

vol. xxvii., pp. 653-1297; and from the discussions on the Regency Bill from the beginning of November, 1810, to the middle of February, 1811, which nearly fill the 18th volume of the 'Parliamentary Debates.' One of the speeches which attracted most attention on the latter occasion for its argument and research (that delivered by John Leach, Esq., afterwards vice-chancellor) was published in an authentic form, and may on this subject be usefully consulted.

JUSTICES OF THE PEACE are persons appointed to keep the peace within certain prescribed limits, with authority to act judicially in criminal causes, and in some of a civil nature arising within those limits, and also to do certain other things in which they act not judicially but ministerially, that is, as servants of the crown performing official acts in respect of which they are entrusted with no judicial discretion. The authority of justices of the peace is derived from the king's prerogative of making courts for the administration of the law, or created by different statutes; their duties are expressed in the royal commission appointing them to the office, or are prescribed by those statutes.

Before the reign of Edward III. there were in every county conservators of the peace, whose duty it was to afford protection against illegal force and violence. These conservators were chosen by the freeholders assembled in the county court under the king's writ.

The lord chancellor, the judges of the king's bench, and every sheriff and coroner, were conservators, and are now justices of the peace, by virtue of their office; and some lands are holden under the service annexed to the tenure of such lands of being conservators of the peace, or of providing fit persons to perform the duties of that office. High and petty constables are also by virtue of their offices conservators of the peace. The authority of conservators of the peace at the common law was the same as that now exercised by constables within their respective townships; and their duty consisted in acting themselves, and commanding the assistance of others, in arresting and quieting those who in their presence and within the limits of their jurisdiction went about to break the peace.

The following account is generally given of the origin of the present justices of the peace. Upon the compulsory resignation of Edward II., Edward III., or rather his mother Isabella, in his name, sent writs to the different sheriffs, stating that his accession had taken place with his father's assent, and commanding that the peace should be kept on pain of disinheritorship and loss of life and limb. Within a few weeks from this time it was ordained, by 1 Edward III., stat. 2, c. 16, that for the better keeping and maintaining of the peace in every county, good and lawful men who were not maintainers of barrettry (malveiz barrets) should be assigned to keep the peace. The mode in which these new keepers of the peace were to be assigned was construed to be by the king's commission; and this ordinance had the double effect of transferring the appointment from the people to the crown, and of laying a foundation for the gradual accession of those powers which are now exercised by justices of the peace.

By 12 Richard II., c. 10, the wages of justices of the peace were fixed at four shillings per day of sessions, and two shillings for their clerks, payable out of the fines and amerciaments at such sessions; but these wages, like those of members of parliament, have long ceased to be received, and the provisions respecting them were repealed by the stat. 18 & 19 Vict. c. 126.

Justices of the peace are appointed either by act of parliament, by royal charter (in the case of justices in boroughs not within the Municipal Corporation Act the charter usually appointing certain municipal officers to be justices, and prescribing the manner in which vacancies in the offices are to be filled up), or by a commission from the crown under the statute of 1 Edward III. The form of the commission of the peace has from time to time been altered, and the authority of the justices enlarged. As now framed it consists of two distinct parts, and contains two separate assignments or grants of authority. Of these the former gives to any one or more justices not only all the power relating to the maintenance of the peace which was possessed by the conservators at common law, but also all the additional authority mentioned in the statutes. The latter assignment defines the power of justices when the whole body, or such of them as choose to attend, act together in general sessions. [SESSIONS.]

By 5 Geo. II., c. 18, no attorney, solicitor, or proctor shall be a justice of the peace for any county whilst he continues in practice, and a similar provision is contained in the 6 & 7 Vict., c. 73, s. 33. By 18 Geo. II., c. 20, no person shall be capable of acting as a justice of the peace for any county, riding, or division, within England or Wales, who shall not have, in law or equity, to and for his own use and benefit, in possession a freehold, copyhold, or customary estate for life, or for some greater estate, or an estate for some long term of years determinable upon life or lives, or for a certain term originally created for twenty-one years or more, in lands, tenements, or hereditaments in England or Wales, of the clear yearly value of 100*l.* over and above all incumbrances affecting, and all rents and charges payable out of or in respect of the same, or who shall not be seised of or entitled to, in law or equity, to and for his own use and benefit, the immediate reversion or remainder of and in lands, tenements, and hereditaments, leased for one, two, or three lives, or for any term of years determinable on lives upon reserved rents, and which are of the yearly value of 300*l.*, and who shall not have taken and subscribed an oath stating the nature of

the qualifying estate. The third section of this statute imposes a penalty of 100*l.* upon those who act without having taken and subscribed the oath, and for acting without being qualified. The statute, however, excepts from these provisions certain official persons, &c., and other exceptions have been since introduced. Thus the judges of the County Court may sit without the qualification (9 & 10 Vict., c. 95, s. 21.) A justice of the peace cannot legally act after he has ceased to be qualified; but it is not necessary that he should continue to retain the same qualification, nor will the absence of a qualification render his acts absolutely void.

Justices appointed by Act of Parliament or by the king's charter are not removable except for misconduct, but the authority of a justice appointed by the king's commission may be determined at the pleasure of the crown, either directly by writ under the great seal, or impliedly, by making out a new commission, from which his name is omitted. But until notice of the revocation of the authority, or publication of a new commission, the acts of the ex-justice are valid in law, and the warrant of a justice remains in force until it be executed, although he die before its execution. The commission is also determined by the death of the king by whom it was issued; but by 6 Anne, c. 7, s. 8, all offices, civil and military, are to continue for six months after the demise of the crown, unless sooner determined.

The 9 Geo. IV., c. 17, repeals the statutes which imposed the taking the sacrament of the Lord's Supper as a qualification for office, and requires the following declaration:—"I, A B, do solemnly and sincerely, in the presence of God, profess, testify, and declare, on the true faith of a Christian, that I will never exercise any power, authority, or influence which I may possess by virtue of the office of justice of the peace, to injure or weaken the Protestant church as it is by law established in England, or to disturb the said church, or the bishops and clergy of the said church, in the possession of any rights or privileges to which such church or the said bishops or clergy are or may be entitled." The omission to subscribe this declaration does not subject a person acting as a justice of the peace to any penalty; the statute (s. 5) merely renders the appointment void; and whilst the justice continues in the exercise of his office his acts are not either void or voidable so as to affect the rights of those who are not privy to such omission.

The judicial authority of a justice out of sessions is both civil and criminal: civil, where he is authorised by statute to adjudicate between master and servant, or to enforce the payment of rates, tithes, &c.; criminal, where he requires surety of the peace or a recognisance for the peace or for good behaviour, or where he acts in the suppression of riots, or where he acts with summary power to decide upon the guilt or innocence of the party accused, according to the view which he may take of the evidence, and to punish the offender. But all proceedings before justices, whether civil or criminal, if removed into the Queen's Bench, are there treated as belonging to the crown side of the court.

By two Acts of Parliament (11 & 12 Vict. cc. 42 & 43), commonly called 'Jervis's Acts,' repealing various earlier statutes, the duties of justices of the peace out of sessions (that is, when not assembled in quarter or general sessions for the county) in England and Wales are facilitated and defined. The one statute (c. 42) relates to the duties of justices out of sessions with respect to persons charged with indictable offences, and the other (c. 43) to summary convictions and orders.

Under the former statute, where a charge or complaint is made before a justice, that any person has committed, or is suspected to have committed, any treason, felony, or indictable misdemeanor, or other indictable offence whatsoever within the limits of the jurisdiction of the justice, or that any person guilty, or suspected to be guilty, of having committed any such crime or offence elsewhere, is residing within such jurisdiction, the justice may issue a warrant under seal directed to peace officers for his apprehension, founded on information on oath (or a summons not founded on oath in the first instance, followed by a warrant if disobeyed). Upon the accused person being brought before the justices, they must, before committing him to prison for trial or admitting him to bail, in his presence (but in open court or privately, at their discretion), take the statement on oath of the witnesses (to compel the attendance of whom justices have power to issue summonses and warrants), and reduce the evidence into written depositions, to be signed by the witnesses. These depositions are read over to the accused, and his own statement (if any) taken in a prescribed form, so as to exclude any threat or inducement. Ample powers are given to the justices to remand, dismiss, commit for trial, or hold the accused to bail, and to bind over prosecutors and witnesses by recognisance.

By more recent statutes, instead of committing for trial, justices may summarily convict (unless the accused prefers to be tried by a jury) in trifling cases of larceny, or where the offenders are under sixteen. (See 10 & 11 Vict. c. 82; 18 & 19 Vict. c. 126; 19 & 20 Vict. c. 118; and Blackstone's 'Commentaries,' by Kerr, vol. iv., p. 333.) Justices may also issue warrants to apprehend parties against whom indictments have been already found, and without further inquiry commit them for trial or admit them to bail, or, if already in prison, may order their detention.

The 11 & 12 Vict. c. 43, relating to summary convictions, empowers the justices to issue a summons; or, for any offence punishable on conviction, they may issue a warrant (founded on an information on

oath) in the first instance. If a summons be issued in the first instance (and this is the general mode of proceeding), and it is not obeyed, the justices may either issue a warrant or proceed *ex parte*. When, however, the application for any order of justices is by law to be made *ex parte*, there is no necessity for issuing any summons. In cases of complaints upon which the justices may make an order for payment of money or otherwise, it is not necessary that the complaint should be in writing. There is similar power to compel the attendance of witnesses, as in cases of indictable offences. Every complaint and information is heard and determined by one or more justices (unless any particular Act requires more than one) in open court, and both parties may appear by counsel or attorney. General forms of convictions and orders are given, to prevent the numerous technical objections to which they were previously often open. The convictions or orders may be enforced by distress, or imprisonment in default (see also 21 & 22 Vict. c. 73, s. 5), or, in the first instance, according to the nature and circumstances of the case and the special provisions relating to it. The justices have also general powers to award costs, which are also recoverable by distress and imprisonment in default.

In matters relating to the revenue, or to the poor, and to certain other things, the special provisions of the statutes on those subjects are to be followed by the justices.

In cases of summary convictions and orders, parties dissatisfied with the decision of justices in point of law may require them to state a case for the opinion of any one of the three superior courts of common law (20 & 21 Vict. c. 43); and this power is very extensively acted upon.

Power has been expressly given to justices to direct the prosecution for perjury of witnesses before them. (14 & 15 Vict. c. 100, s. 19.)

Justices of the peace have in general no authority over matters arising out of the county or place for which they are appointed, and therefore their warrants can in general only be executed by apprehending the offender within the jurisdiction of the justice, except in case of "fresh pursuit," at any place within seven miles of the border. But when the person is not found, or has escaped, any justice of the county where he is supposed to be, may give effect to the original warrant by an indorsement authorising its execution within his own jurisdiction. This, which is termed "backing the warrant," is done upon proof of the handwriting of the justice who issued it; and the person, when apprehended, is then taken before the justice who issued the warrant, unless the prosecutor or any of the witnesses may be in the county where the apprehension takes place, in which case the examinations may proceed there. This power to back warrants is not confined to the case of counties, but English warrants may be backed in Ireland, Scotland, or the Isle of Man and Channel Islands (see 14 & 15 Vict. c. 55, s. 18), and *vice versa*.

In the case of indictable offences committed on the high seas or abroad, warrants may be issued by justices of the county or place where the offender may be.

So, although justices of the peace when they are out of the county, &c., for which they are appointed have in general no coercive power, yet where a justice is also a justice for an adjoining county he may act for and deal with offenders in one county while in the other. So, also, a justice for a county may act in any city, town, or precinct within or adjoining to it; and there are similar provisions with respect to detached parts of counties. The powers of metropolitan police magistrates and of stipendiary magistrates are regulated by special statutes and provisions.

Justices ought not to exercise their functions in cases in which they are themselves the persons injured. They should cause the offenders to be taken before other justices, or, if present, should desire their aid.

When justices refuse to hear a complaint over which they have jurisdiction, or to perform any other duty which the law imposes on them, the party aggrieved by such refusal may apply to the court of Queen's Bench for a rule (founded upon an affidavit of the facts) calling upon the justice and the parties interested to show cause why the act required (11 & 12 Vict. c. 44, s. 5) should not be done. This is a more expeditious and cheaper mode of proceeding than the former mode by mandamus; and, moreover, the order of the court to do any act, protects the justice, which a mandamus did not. [MANDAMUS.]

Justices of the peace are strongly protected by the law in the execution of their office. Opprobrious words which would not subject the speaker to any proceeding, civil or criminal, if uttered under other circumstances, yet if spoken of a justice whilst actually engaged in his official duties may be made the subject of an action or of an indictment, or if spoken in the presence of the justice may be punished by commitment to prison as for a contempt of court.

Where a justice of the peace acting in or out of sessions acts judicially in a matter over which he has jurisdiction, and does not exceed his jurisdiction, he is not liable to an action however erroneous his decision may be; nor will even express malice or corruption entitle a party aggrieved by such decision to any remedy by action: the delinquent magistrate is answerable only to the crown as for an offence committed against the public. Where the justice has no jurisdiction or exceeds his jurisdiction, or having jurisdiction deviates from the prescribed legal form to an extent which renders the proceedings void, or where a conviction under which the justice has granted a warrant is set aside by a superior court, an action will lie against the justice to

recover damages in respect of any distress, imprisonment, or other injury which may have resulted from his acts, though done without malice or other improper motive. But even in these cases, if the justice has acted *bona fide* in his magisterial capacity, if he has intended to act within his jurisdiction, though by mistake he may have exceeded it and not acted within the strict line of his duty, and also in cases where a justice has acted or intended to act in the execution of his ministerial duties, he is entitled to the protection of several important statutory regulations, though where there is no colour whatever for a belief or supposition on the part of the justice that he is acting within his jurisdiction, where the act is wholly alien to the magisterial functions and done *diverso intuitu*, these regulations do not apply.

By the 11 & 12 Vict. c. 44 (another of 'Jervis's Acts'), reciting that it is expedient to protect justices of the peace in the execution of their duty, and repealing various previous provisions from the reign of James I., having the same object, no action brought against a justice of the peace for any act done by him in the execution of his duty with respect to any matter within his jurisdiction, can be maintained unless it be proved that the act was done maliciously, and without reasonable and probable cause: and with respect to acts done by a justice in a matter of which by law he has not jurisdiction, or in which he has exceeded his jurisdiction, if done under a warrant or colour, no action can be maintained until the conviction or order has been quashed; and no action can be brought after a conviction or order confirmed on appeal. If it be proved that the plaintiff was actually guilty of the offence, he cannot recover more than twopence damages without costs. Every action against a justice must be commenced within six months, and one month's notice of action must be given. Wherever a discretionary power is given to a justice, no action is maintainable by reason of the manner in which that discretion has been exercised.

When a justice acts with partial, corrupt, or malicious motives he is guilty of a misdemeanor, for which he may be indicted, and in a clear case of misconduct the Court of Queen's Bench, which exercises a general superintendence over the conduct of those to whom the administration of the criminal law of the country is entrusted, will, if the application be made without delay, give leave to file a criminal information. But the court will consider, not whether the act complained of be strictly right or not, but whether it proceeded from unjust, oppressive, or corrupt motives, among which motives fear and favour are both included. If the affidavits filed in support of the application disclose nothing which may not be attributable to mere error or mistake, the court will not even call upon the justice to show cause why a criminal information should not be filed. The court will not entertain a motion for a criminal information against a justice of the peace, unless notice of the intended application have been given in sufficient time to enable him, if he thinks proper, to meet the charge in the first instance by opposing the granting of the rule to show cause.

The proceedings after an information has been filed or an indictment found against justices of the peace for criminal misconduct are the same as in other cases of misdemeanor. If the defendant suffer judgment by default, or is found guilty by the verdict of a jury, the punishment is by fine or imprisonment or both; after which an application may be made to the lord chancellor to exclude him from the commission; and when affidavits are filed in the Queen's Bench impeaching the conduct of justices of the peace, such affidavits are sometimes directed by the court to be laid before the chancellor, to enable him to judge whether such persons ought to remain in the commission.

The institution of justices of the peace has been adopted in most of the British colonies, and has with some modifications been retained in the United States of America.

JUSTICIAR OF SCOTLAND. The earliest individual in this high office which extant records name seems to be Geoffrey de Maleville, of Maleville, in the county of Edinburgh, *temp.* Malcolm IV.

The term "Scotland" was then less extensive in its application than at present; it designated, properly speaking, not the whole territory of the realm, but that part only which lay north of the Forth, or *Scots sea*, as it was called; and accordingly, contemporary with Maleville there was another justiciar, David Olifard, justiciar of Lothian, that is to say, the territory south of the Forth, excepting the district of Galloway, which had long its own peculiar laws and customs. About the middle of the 13th century, however, Galloway too had its justiciar, so at this time there were *three* justiciars in the realm of Scotland—a justiciar of Galloway, a justiciar of Lothian, and a justiciar of Scotland strictly so called. They were all probably of co-ordinate authority: each, next to the sovereign, supreme in his district; but the district of the last was the most extensive, and, containing within it the metropolis of the kingdom, it was also no doubt the most important and the most coveted. The justiciars of Scotland were accordingly the most conspicuous men of the time:—the Comyns, earls of Buchan; the MacDuffs, earls of Fife; Melville; and Sir Alan Durward. This last had an eye to the crown itself, for having married the illegitimate daughter of King Alexander II., he gained over the chancellor to move in council her legitimation, and that, on failure of issue of the king's body, she and her heirs might inherit her father's throne. But the king conceived so great a displeasure at this, that he immediately turned the chancellor out of office, and soon afterwards the justiciar also. The proud

Durward removed to England, joined King Henry III. in France, and served in his army, till in a few years he was, by the influence of the English king, restored to his office of justiciar, whence he was displaced only by the more powerful Comyn. The incident in Durward's life to which we have just alluded, was not singular: the justiciar was *caput legis et militie*, at the head both of the law and also of the military force of the kingdom, and repeated instances occur in early times of their military prowess as well as judicial firmness.

The death of King Alexander III. left the crown open to a competition which allowed Edward I. of England to invade the kingdom. In 1292 the English Court of King's Bench sat for some time in Roxburgh; and in 1296, Sir William Ormesby, a justice of the Common Pleas and justice in eyre in England, was constituted, by Edward, lord justiciar of Scotland. This appointment was of short duration; but in 1305, Edward, having again put down the Scots, distributed the kingdom into four districts, and constituted for each district two justices (an Englishman and a Scotchman), in the nature of the English justices of assize—with a view to put the whole island under one and the same judicial system. Edward's early death, however, rendered the scheme abortive; and Galloway had soon its own laws, and Lothian and Scotland their justiciars as before, with this difference, that the metropolis of the kingdom was now shifting southwards to Edinburgh, and the term Scotland, in its strict acceptation, had given place to the appellation "north of the Forth." Sir Hugh de Eglinton, justiciar of Lothian in the middle of the 14th century, and distinguished for his poetical genius, was now therefore "Hugh of the Awl Ryal," or of the royal palace; and towards the end of the next century Andrew, Lord Gray, was advanced from the situation of Justiciar North of Forth to that of Justiciar South of Forth. He continued in this place with approbation for eleven years, and died but a few months before the calamitous affair of Flodden.

On this event, which happened in the beginning of the 16th century, the office of lord justiciar, or, as he was now styled, justice-general (in contradistinction to the special justiciars, now frequently appointed as well for particular trials as for particular places and districts), came into the noble family of Argyle, where it was hereditary for a century, and comprehended at once the entire kingdom. The High Court of Justiciary then also began to be settled at Edinburgh, and the regular series of its records, or books of adjournment, to commence. It was at this time also that the Court of Session was erected by ecclesiastical influence. Various attempts had been made by the clergy in former reigns to establish such a court. In 1425 the first "Court of the Session" was instituted under the influence of Wardlaw, bishop of St. Andrew's, and founder of the university there; but immediately on his death, which happened soon after, it drooped and expired. In 1458 Bishop Shoreswood, the king's secretary, tried to revive it; and about thirty years after, Elphinstone, Bishop of Aberdeen, did so likewise. In 1494, however, the latter founded, or rather re-founded, the university of Aberdeen, and had interest enough to get an act passed in parliament to enforce in all the courts of the kingdom the study and practice of the Roman laws; and in 1503 the "Court of Daily Council" was established. This court had a more extensive jurisdiction than the former; it was universal, being instituted to decide all manner of summonses in civil matters, complaints, and causes daily as they happened to occur; and it was calculated to be permanent. But the present was not an opportunity to be lost; and accordingly, in the minority of King James V. and while the nation was weakened and distracted by the loss at Flodden, the Court of Session was established under the lord chancellor, and with a majority of ecclesiastics both on its bench and at its bar. The consequence was, that from that day forward the Court of Justiciary declined; its civil jurisdiction ceased, being engrossed by the Court of Session; and the latter became in its place the supreme court of the kingdom. The Reformation effected a change in the composition of the Court of Session, but not much in its position or powers; and in 1672 an act was passed in parliament constituting a certain number of the judges, or lords of session, judges of justiciary under the justice-general and justice-clerk, who was now made vice-president of the Court of Justiciary.

Nothing else of consequence touching the constitution of the court occurred till, by 1 Will. IV., c. 69, s. 18, the office of lord-justice-general, which had become in a manner a perfect sinecure, was appointed to devolve on and remain with the office of lord-president of the Court of Session, who should perform the duties thereof as presiding judge in the Court of Justiciary. The effect of this enactment was to place the lord-justice-general again at the head of the administration of the law; and thus, by a singular revolution, restore him, after the lapse of 300 years, to his former situation of lord-chief-justice of Scotland.

JUSTICIARY, CHIEF, of England (*Capitalis Justitarius Angliæ*). None either of the English lawyers or legal antiquaries who have handled this subject have given at all a satisfactory explanation of it. In order to comprehend the functions of the great officer, it is necessary first to understand those of "The Grand Seneschall, or Dapifer—Seneschallus, or Dapifer Angliæ: in modern phraseology, the lord high steward—comes palatii, major domus regie, or maire du palais. The word *seneschall*, about the etymology of which opinions vary somewhat, meant originally a sort of steward in the household of the Frank kings. After their conquest of Gaul, it came to signify a high political

dignity. Dapifer means the same thing, being the Latin synonyme for it. This officer was the highest in the state after the king, executing all the chief offices of the kingdom as the king's representative. He was not only at the head of the king's palace, but of all the departments of the state, civil and military, chief administrator of justice, and leader of the armies in war. This is proved not only to have been the case in France, by Ducange and other high authorities, as well as by the public records of that kingdom, but to have been so also in England, by a document published by Madox, from the black and red books of the Exchequer, the celebrated 'Dialogus de Scaccario,' written in the time of Henry II.; and likewise by certain MSS., preserved in Sir Robert Cotton's collection in the British Museum, particularly an old MS. entitled 'Quis sit Seneschallus Angliæ, et quid ejus officium.' ("Pict. Hist. Eng." i. 567.)

By the nature of the feudal system everything had a tendency to be given in fief. Among other things, the office of seneschal was given in fief too, and became hereditary among the Franks, Normans, and at the conquest of England, among the Anglo-Normans. In France, under the Merovingian dynasty, the office was in the family of Charles Martel, from whom sprung the Carolingian dynasty; afterwards the Plantagenet counts of Anjou were hereditary seneschals of France; and in England this high office was granted by William the Conqueror to the Grantmesnils, and thence came by marriage to the earls of Leicester. After the attainder of the family of Montfort, earl of Leicester, the office was given to Edmund, the second son of king Henry III., and it then remained in the royal family till its abolition—Thomas Plantagenet, second son of king Henry IV., being the last permanent high steward, the office being conferred afterwards only *pro unica vice*.

In France, when the office became hereditary in the counts of Anjou, it soon became necessary, for various reasons, to have another seneschal, or dapifer, besides the hereditary one; and this officer, whether he be considered as the representative or deputy of the hereditary seneschal, still took precedence, as appears from the charters of the French kings, of all the other great officers of state. In England also something of the same kind took place, but with this difference—that the various functions of the original grand seneschal, or *seneschallus Angliæ*, were divided into two parts, and committed to two distinct officers as his representatives: the judicial functions being committed to an officer styled the High, or rather Chief Justiciary; the administrative and those relating to the affairs of the king's palace or household, to an officer styled, not the *Seneschallus Angliæ*, but the *Seneschallus, or Dapifer Regis*. This explanation will be found to completely remove the confusion that has so long prevailed among the English historians, antiquaries, and lawyers on this subject. And this view of the subject, if it needed it, would be corroborated by the high privileges of the officer created in later times, to preside in the House of Lords at state trials, which officer, be it observed, is not "high justiciary," but "lord high steward," that is "*Seneschallus Angliæ*." This explanation also removes the difficulty of accounting for the extraordinary powers of the lord high steward's court, which some English lawyers have attempted to get over by saying that the lord high steward succeeded to some of the powers of the high justiciary, whereas he merely exercises powers which he had delegated to the high justiciary.

The chief justiciary was usually, even in those times, when, from the circumstance of the king and the great officers of his household acting as judges, we may conclude that a special education was not considered absolutely necessary to fit a man for the judicial office, a person who had given particular attention to the study of jurisprudence. As the representative of the judicial portion of the grand-seneschal's power, his authority extended over every court in the kingdom. For as to what Blackstone says of the court of the marshalsea, that is, the court of the lord steward of the king's household, having never been subject to the jurisdiction of the chief justiciary and no writ of error lying from it to the king's bench, it merely amounts to this, that the court of the lord steward was in fact originally the court of the lord high steward, and in that court either of his representatives, the chief justiciary or the lord steward, might preside.

The chief justiciary not only presided in the king's court and in the exchequer, but he was originally (or rather when the lord high steward fell into abeyance, partly from dread of his power and partly from the impossibility of securing an hereditary succession of the qualities necessary to fulfil his great and numerous duties), by virtue of his office, regent of the kingdom during the king's absence; and at those times writs ran in his name, and were tested by him. And in this light the chief justiciary is regarded as having been the greatest subject in England. One of the most distinguished men who held this high office was Ranulph de Glanville, who is usually regarded as the author of the 'Tractatus de Legibus et Consuetudinibus Angliæ,' the oldest book extant on English law.

The last who held the office and bore the title of *Capitalis Justitarius Angliæ* was Philip Basset; and the first who held the office of *Capitalis Justitarius ad placita coram Rege tenenda*, that is, chief justice of the king's bench, was Robert de Bruis, appointed in the fifty-second year of Henry III. Sir Edward Coke was fond of indulging his vanity by bestowing the same title, "Chief Justice of England," upon himself and on the Grand Justiciary, the mighty *Capitalis*

Justitiarius Angliæ; which was noticed by Lord Chancellor Ellesmere in his address to Sir Henry Montague, Coke's successor, upon his being sworn in chief justice, in these words:—"instead of containing himself within the words of the writ to be the chief justice, as the king called him, 'ad placita coram nobis tenenda.'"

JUSTICIARY COURT in Scotland. The High Court of Justiciary is the supreme criminal court in Scotland. It consists of the lord justice general, lord justice clerk, and five other judges of the Court of Session, and sits at Edinburgh, from time to time during the year, according to the extent of business to be transacted. Offences committed in Edinburgh and within the district of the Lothians are tried before this court, and in cases where in other parts of the country waiting for the next Circuit Court would create too much delay, or where there is any other ground of expediency, the trial may proceed before the Central Court. Other trials in the provinces proceed before the circuit courts, which are held in spring and autumn, each by two judges, or as they are termed Lords Commissioners of Justiciary. The southern circuit is held at Jedburgh, Ayr, and Dumfries; the western, at Glasgow, Inverary, and Stirling; and the northern at Perth, Aberdeen, and Inverness. An additional circuit is held at Glasgow in winter. Questions may be *certified* from the circuit courts to the High Court of Justiciary, that is to say, before being decided the matter may be reserved for the consideration of that court. But it is a peculiarity both of the central and circuit courts of Justiciary, that no decision once given can be reconsidered either by the court pronouncing it or a Court of Review. This principle is liable to many objections; and is productive of but one benefit, that no trial is thrown away by the subsequent discovery of flaws in initial procedure. Before the case goes to a jury, a judgment is pronounced "finding the indictment relevant," and virtually declaring the initial procedure regular; that the charge is properly laid, and the offence if proved punishable. Any objections to the regularity of the proceedings must therefore be stated before judgment, which when once pronounced is final. All cases before the Court of Justiciary are tried by a jury of fifteen, a majority returning the verdict where they are not unanimous. It has jurisdiction in all the more serious offences except high treason, which can only be tried under a commission of Oyer and Terminer, in which English judges would now probably be included.

JUSTIFIABLE HOMICIDE. [MURDER.]

JUSTIFICATION is used in theology to signify the acceptance of a sinner by God, and is frequently employed by the sacred writers as equivalent to the forgiveness of sin. Thus, St. Paul says, "Be it known unto you therefore, men and brethren, that through this man is preached unto you the forgiveness of sins, and by him all that believe are justified from all things, from which ye could not be justified by the law of Moses." (Acts, xiii. 38, 39.) The Protestants and Roman Catholics differ respecting the signification that should be attached to the word justification. The former maintain that the

Hebrew word *הַצְדִּיק*, and the Greek words *δικαιοῦν* and *δικαίωσις*, are almost invariably employed in the Bible in a judicial sense; that is, to declare a person righteous notwithstanding the sins he has committed, and to deliver him from the punishment which his sins had deserved. The latter interpret the words in a physical sense; and maintain that to be justified is not to be reckoned righteous by God, but actually to be made righteous by the infusion of a sanctifying principle. The Protestants, on the contrary, believe, that though sanctification is a consequence of justification, yet it is a distinct and separate operation.

The reason or cause of our justification is generally divided by theologians into the originating, the meritorious, and the instrumental, cause, or the *causa efficiens*, the *causa meritoria*, and the *causa apprehendens*.

1. The *Originating cause* is the love of God towards his fallen creatures (Rom. iii. 24; Eph. ii. 8). 2. The *Meritorious cause* is, according to the 11th article of the Church of England, and the opinion of most Protestants, "the merit of our Lord and Saviour Jesus Christ, and not our own works or deservings" (Rom. iii. 25; v. 18; Eph. i. 7; Col. i. 14); but the Roman Catholic church maintains that good works, penances, and the intercession of saints also contribute to our justification. 3. The *Instrumental cause* is faith in the vicarious sacrifice of Christ; since the merit of Christ's sacrifice does not produce our pardon, unless we believe in its efficacy.

The consequences of justification are said to be: 1. Peace with God (Rom. v. 1); 2. Tranquillity of conscience; 3. Adoption of the persons justified into the family of God (Rom. viii. 14-17); 4. Spiritual joy, arising from the belief of our being adopted by God ('Rom.' xiv. 17); 5. The hope of eternal life.

JUSTINIAN'S CODE, or LEGISLATION. Justinian, soon after ascending the throne, gave orders (Feb. A.D. 528) to a commission consisting of Joannes and nine other persons, among whom were Tribonian and Theophilus, to make a general compilation of the best and most useful laws, or "constitutions," which had been promulgated by the emperors his predecessors, beginning from Hadrian's perpetual edict down to his own time. [CONSTITUTIONS, ROMAN.] Partial compilations had been made in the time of Constantine by private individuals, Gregory and Hermogenes, of which only fragments remain, and a more complete one was effected under Theodosius II.

[THEODOSIAN CODE.] All these were now merged in the new code of Justinian. Joannes and his nine associates completed their task in fourteen months, and the new code, having received the imperial sanction, was published in April, A.D. 529. A few years after, Justinian, by the advice of Tribonian, ordered a revision of his code to be made by Tribonian and four others. The commissioners suppressed several laws, as either useless or inconsistent with present usage, and added many constitutions which the emperor had been promulgating in the mean time, as well as fifty decisions on intricate points of jurisprudence. The code thus revised was published in December of the year 534, under the title of 'Codex Justinianus repetitæ prælectionis,' and thenceforth had the force of law.

The Code is divided into twelve books; every book is subdivided into titles, and each title into laws. Book i. treats of the Catholic faith, defines its creed agreeably to the first four general councils, forbidding public disputations on dogmas; it then treats of the rights, privileges, and discipline of bishops and other ecclesiastical persons; next of heretics, Samaritans, Jews, apostates, &c., against whom it contains several penal enactments; after which the book proceeds to speak of the laws, and their different kinds, and lastly of the magistrates. Book ii. treats of the forms to be observed in commencing a suit; then of restitution, compromises, sureties, and lastly of the oath of calumny.* Book iii. treats of judicia and judices, and judicial proceedings generally; of holidays, of the various jurisdictions, of illegal (inofficiosa) testaments and donations, of dowries and inheritances, of the Lex Aquilia, of mixed actions, of actions for crimes committed by slaves, of gaming, of burying-places and funeral expenses. Book iv. begins with the explanation of personal actions which are founded on loan and other causes; of obligations and actions, with their effect in relation to heirs and other persons bound by them; of testimony and written evidence; of things borrowed for use; of contract by pledge, and the personal action thereon; of compensation, interest, deposit, mandate, partnership, buying and selling, permutation, hiring, and emphyteutic contracts. Book v. treats of betrothment, gifts in contemplation of marriage, of marriages, women's portions, and the action that lies for the recovery of the dowry, of gifts between husband and wife, of estates given in dowry, of alimony, of concubines, natural children, and the process of legitimation. It next treats of tutorships (tutela), of the administration by tutors, and of the alienation of minors' estates. Book vi. treats of slaves, and freedmen, and the rights of their patrons; then it explains at large the Prætorian possession called "Bonorum possessio;" after which it expounds the whole matter of testaments, as institutions and substitutions of heirs, preteritions and disinheritions, refusals of inheritance, the opening of wills, codicils, legacies, and fiduciary bequests, and lastly succession to the property of intestates. Book vii. treats of manumissions; afterwards of matters relating to prescription, of judgments (sententiæ) and appeals, of the cession of estate or goods, of the seizure of goods, of the privileges of the exchequer, those of dowries, and the revocation of alienations made to defraud creditors. Book viii. begins with interdicts: it then treats of pledges and pawns, of stipulations, novations, delegations, &c. It treats next of the paternal power, of the emancipation of children and their ingratitude; it then explains what is meant by custom, or unwritten law; it next speaks of gifts (donationes mortis causâ, &c.) and their various kinds; and lastly, of taking away the penalty of celibacy. Book ix. treats of crimes, criminal judgments and punishments. Book x. treats of the rights and prerogative of the exchequer, of vacant goods, of treasurers, taxes levied upon the people, and tolls; of the decuriones and their office, of the freedom of citizens, of domicilia, of public offices and exemption from them, and of the various kinds of public offices and functions appertaining to them. Book xi. treats of the rights common to the city of Rome and municipal towns, the right of having corporate bodies and communities, and the right of having public registers. Book xii. continues the same subject, explaining the right of cities as to having offices civil and military, and also as to having functionaries for the execution of judgments and the orders of magistrates.

In the year following the publication of the first edition of his Code, Justinian undertook a much greater and more important work; to extract the spirit of jurisprudence from the decisions and conjectures, the questions and disputations, of the Roman civilians. In the course of centuries, under the republic and the empire, many thousand volumes had accumulated, filled with the learned lucubrations of the jurisconsults, but which no fortune could purchase, and no capacity could digest. The jurisconsults ever since the time of Augustus had been divided into opposite schools, and thus conflicting opinions were often produced, which only served to puzzle those who had to decide what was law. To put order into this chaos, was the object of Justinian. In December, 530, he commissioned seventeen lawyers, with Tribonian at their head, with full authority to exercise their discretion as to the works of their predecessors, by making a choice of those whom they considered as the best authorities. They chose about forty out of Tribonian's library, most of them jurisconsults who had lived during that period of the empire which has been sometimes called the age of the Antonines, from Hadrian to the

* Many of the terms here used are terms of Roman law, and as such do not admit of translation by equivalent English terms.

death of Alexander Severus. From the works of these writers, said to have amounted to two thousand treatises, the commission appointed by Justinian was to extract and compress all that was suited to form a methodical, complete, and never failing book of reference for the student of law and the magistrate. Justinian gave Tribonian and his associates ten years' time to perform their task; but they completed it in three years. The work was styled 'Digesta,' and also 'Pandectæ' ("embracing all") and was published in December, 533. It was declared by the emperor that it should have the force of law all over the empire, and should supersede all the text books of the old jurists, which in future were to be of no authority.

The following is a list of the Roman jurists from whose works the 'Pandect' or 'Digest' was composed, with their several epochs, so far as they can be ascertained, and the relative proportions which they have contributed to the 'Pandect.' Where (a) is added, the contribution is less than 1. The sum total of all the figures denotes the whole amount, of which the several figures opposite each jurist's name denote the proportion which his part bears to the whole. In addition to the extracts contained in the 'Pandect' from each author, many of them are very often merely cited.

Aburnus (Valens).	
Ælius (Gallus, Marcianus).	
Æmilius (Macer, Papinianus).	
Africanus, lived in Hadrian's time and was a disciple of	
Salvius Julianus	24
Alfenus, a native of Cremona, and a pupil of Servius Sulpicius,	
who died B.C. 43.	9
Anthianus, time unknown	(a)
Anthus (Anthianus).	
Antistius (Labeo).	
Aquila, supposed by some to have lived under Sept. Severus	(a)
Arcadius, under Constantine the Great	2½
Arrius (Menander).	
Aurelius (Arcadius).	
Cæcilius (Africanus).	
Caius (Gaius).	
Callistratus, under Caracalla	17½
Celsus, lived under Trajan and Hadrian	23
Ceridius (Scævola).	
Charisius (Arcadius).	
Claudius (Hermogenianus, Saturninus, Tryphoninus).	
Clemens (Terentius).	
Domitius (Ulpianus).	
Florens (Tertullianus).	
Florentinus, time uncertain, supposed to have lived under	
Alex. Severus	4
Furius (Anthianus).	
Gaius, lived under Antoninus and Aurelius	72
Gallus, Aquilius, a friend of Cicero, with whom he was prætor,	
B.C. 66	(a)
Herennius (Modestinus).	
Hermogenianus, under Constantine	9½
Javolenus, lived under Trajan	23½
Julianus, lived under Hadrian, was a pupil of Javolenus, and	
author of the perpetual edict	90
Julius (Aquila, Paulus).	
Junius (Marcianus).	
Justus (Papirius).	
Juventius (Celsus).	
Labeo, lived under Augustus, was the head of the school	
called Proculians from his disciple Proculus	12
Licinius (Rufinus).	
Lucius (Mæcianus, Papinianus).	
Macer, under Alexander Severus	10
Mæcianus, lived under Antoninus Pius	8
Marcellus, under Antoninus and Aurelius	32½
Marcianus, probably under Caracalla	38
Marcus (Labeo).	
Massurius (Sabinus).	
Mauricianus, lived under Antoninus	1½
Maximus, time unknown	(a)
Menander, under Severus and Caracalla	3
Modestinus, flourished under Alex. Severus and the Maximini	41½
Mucius, Quintus, son of P. Mucius Scævola, consul in the year	
659 of Rome, or B.C. 95	1
Neratius, lived under Trajan	10
Papinianus, under Sept. Severus, whose friend he was; was	
put to death by Caracalla	104
Papirius, under Marcus Aurelius	2½
Paternus (Tarruntenus).	
Paulus, flourished under Alexander Severus	297
Pomponius, lived under Antoninus Pius; another Pomponius	
is said to have lived under Alex. Severus	80
Priscus (Javolenus, Neratius).	
Proculus, lived under Nero and Vespasian	6
Publius (Alfenus, Anthianus, Juventius).	
Quintus (Mucius, Tertullianus, Venuleius).	
Rufinus, about the time of Alex. Severus	1½

Rutilius (Maximus).	
Sabinus, Massurius, flourished under Tiberius, was the head	
of the Sabinian school	1½
Salvius (Julianus).	
Saturninus, supposed by some to be the same as Venuleius	1
Saturninus Quintus (Venuleius).	
Scævola, Cervidius, under Antoninus and Aurelius	78½
Scævola, Mucius (Mucius).	
Sæmpronius (Proculus).	
Septimius (Tertullianus).	
Sextus (Pomponius).	
Tarruntenus, under Marcus and Commodus.	(a)
Terentius, lived under Hadrian and Antoninus	3½
Tertullianus, time uncertain, by some supposed to be the same	
as the father of the church	1½
Titus (Gaius).	
Tryphoninus, under Severus and Caracalla	22
Valens, lived under Hadrian and Antoninus Pius	3
Varus (Alfenus).	
Venuleius, under Antoninus and Aurelius	10
Ulpianus, flourished under Alex. Severus, whose counsellor	
he was	610
Ulpian (Marcellus).	
Volusius (Mæcianus).	

If the whole 'Digest' is divided into three equal parts, the contributions of Ulpian are somewhat more than one-third.

The 'Digesta' is divided into 50 books, each book being also divided into titles, and subdivided into laws and paragraphs. The following are some of the principal heads. Book i. lays down the general principles and the different kinds of law; it then establishes the division of persons and of things; then speaks of senators, and of magistrates and their delegates and assessors: ii. treats of the jurisdiction of magistrates; of the manner of bringing actions, of compromises after an action is commenced: iii. explains what kind of persons are allowed to sue in law, and it defines who are styled infamous, and as such not permitted to sue; it then treats of advocates, proctors, syndics, and other counsellors: iv. treats of restitution, compromises, and arbitrations, after which it speaks of innkeepers and others in whose custody we leave anything: v. treats of trials; and complaints against inofficious (inofficiosa) testaments: vi. treats of real actions and their various kinds to recover one's property: vii. treats of personal services (servitutes, as usus fructus): viii. speaks of real services both in town and country: ix. treats of personal actions which are in imitation of real actions, as actions for a fault or crime committed by a slave, the action of the lex Aquilia, and the action against those who throw any thing into the highway by which any one is wounded or injured: x. treats of mixed actions, the action of partition of an inheritance, &c.: xi. speaks of interrogatories, and of such matters as are to be heard before the same judge (judex). It also treats of run-away slaves, of dice-playing, bribery, corruption, and false reports; and lastly, of burials and funeral expenses: xii. explains the action for a loan, conditions, &c.: xiii. continues the subject of the preceding, and treats of the action of pawning: xiv. and xv. treat of actions arising from contracts made by other persons and yet binding upon us; of the Senatus Consultum Macedonianum; and of the peculium: xvi. treats of the Senatus Consultum Velleianum, and of compensation, and the action of deposits: xvii. treats of the mandate, and of partnership (societas): xviii. explains the meaning and forms of the contract of sale, the annulling of this kind of contract; and treats of gain or loss upon the thing sold: xix. treats of bargains, of actions of hiring, of the action called æstimatoria, of permutation, of the action called præscriptis verbis, &c.: xx. treats of pledges and hypothecæ, of the preference of creditors, of the distraction or sale of things engaged or pawned: xxi. contains an explanation of the Ædile's edict concerning the sale of slaves and beasts, and also treats of evictions, warranties, &c.: xxii. treats of interest (usura), fruits, accessions to things, and of proofs and presumptions, and of ignorance of law and fact: xxiii. is upon betrothment (sponsalia), marriage, dowry, and agreements upon this subject, and lands given in dowry: xxiv. treats of gifts between husband and wife, divorces, and recovery of the marriage portion: xxv. treats of expenses laid out upon the dowry, of actions for the recovery of things carried away by the wife or other persons against whom there is no action for theft, of the obligation to acknowledge children and provide for them, on the Rescript De Inspiciendo Ventre, and lastly of concubines: xxvi. and xxvii. treat of tutorship and curatorship, and the actions resulting from them: xxviii. treats of testaments, of the institution and disinheriting of children, of the institution of an heir, of substitutions, &c.: xxix. treats of military testaments, of the opening of wills, and of codicils: xxx., xxxi., xxxii. treat of legacies and fiduciary bequests in general: xxxiii. and xxxiv. treat of particular legacies, of the ademption of legacies, and of the Regula Catoniana: xxxv. treats of legacies on condition, and of the Lex Falcidia: xxxvi. treats of the Senatus Consultum Trebellianum, and of fiduciary bequests, of the time when they become due, of the security to be given by the heir, &c.: xxxvii. treats of universal succession by bonorum possessio: xxxviii. treats of the services due by freedmen to their patrons, of the succession of freedmen, of the succession of intestates appointed by the prætor, of heredes Sui and Legitimi, and of the Senatus Cou-

sultum Tertullianum and Orphitianum: xxxix. explains the means which the law or the prætor provides for preventing any one from receiving damage where a personal, real, or mixed action will not lie, after which it ends with the explanation of donations generally, and of such as are made in contemplation or view of death (mortis causâ): xl. relates to manumission or freeing of slaves: xli. treats of the various ways by which the property of things is acquired, and of the acquisition and loss of possession, and lastly of lawful causes which authorise possession and lead to usucaption: xlii. treats of definitive and interlocutory sentences, of confessions in judgment, of the cession of goods, of the causes of seizure and their effects, of the privileges of creditors: of curators appointed for the administration of goods, and of the revocation of acts done to defraud creditors: xliii. treats of interdicts and possessory actions: xliv. speaks of pleas (exceptiones) and defences, and of obligations and actions: xlv. of stipulations, &c.: xlv. of sureties, novations, delegations, payments, discharges, prætorian stipulations, &c.: xlvii. treats of private offences: xlviii. treats of public offences; then follow accusations, inscriptions, prisons; and lastly it treats of torture, punishments, confiscation, relegation, deportation, and of the bodies of malefactors executed: xlix. treats of appeals; and then gives an account of the rights of the exchequer, and of matters relating to captives, military discipline, soldiers and veterans: l. treats of the rights of cities and citizens, of decuriones and their children, of public offices, of immunities, of deputies and ambassadors; of the administration of things belonging to cities, of public works, fairs, &c.; of taxes laid upon the provinces, concluding with the interpretation and signification of legal terms, and with the rules of law.

Of the merits and imperfections of the 'Digest,' Cujas, Hotomannus, Heineccius, Gravina, Schulting, Bynkershoek, and many others have amply spoken. With all its faults it is a noble work, and much superior to the Code in its style, matter, and arrangement; it has, in great measure, embodied the wisdom of the most learned men of the best age of the empire, men who grounded their opinions on the principles of reason and equity, and who for the most part were personally unconcerned and disinterested in the subjects on which they gave their responsa. Tribonian and his colleagues are charged with making many interpolations, with altering many passages in the writings of their predecessors, substituting their own opinions, and passing them off to the world under the name of the ancient jurists. Justinian himself acknowledged that he was obliged to accommodate the old jurisprudence to the altered state of the times, and to "make the laws his own." Another charge, which is, however, unsupported by evidence or probability, is, that Justinian and his civilians purposely destroyed the old text books that had served them for the compilation of the 'Pandects.' Long, however, before Justinian's time, the works of the ancient jurists were partly lost, and the vicissitudes of the ages that followed may easily have obliterated the rest. While the Digest was being compiled, Justinian commissioned Tribonian and two other civilians, Theophilus and Dorotheus, to make an abridgement of the first principles of the law, for the use of young students who should wish to apply themselves to that science. This new work, being completed, was published under the name of 'Institutiones,' about one month before the appearance of the Digest. The Institutions were mainly based on an older work of the same description and title. [GAJUS, in BIOG. DIV.] They are arranged in four books, subdivided into titles. As the law has three objects, persons, things, and actions, the first book treats of persons or status; the second and third, and first five titles of the fourth, treat of things; and the remaining titles of the fourth book treat of actions. [ROMAN LAW.]

Besides these three compilations, the Code, the Institutes, and the Digest, Justinian, after the publication of the second edition of his Code, continued to issue new laws or constitutions chiefly in Greek upon particular occasions, which were collected and published together after his death under the name of *Neapal Δικτάσεις*, or Novæ or Constitutiones Novellæ, or Authenticæ. The Novellæ are divided into nine Collationes and 168 Constitutiones, or, as they are now often called, novels. The Novellæ, together with thirteen Edicts of Justinian, make up the fourth part of his legislation. There are four Latin translations of the Novellæ, two of which were made soon after Justinian's death; the third is by Haloander, printed at Nürnberg in 1531; and the fourth was printed at Basel by Hervagius in 1561. This first translation is that which is printed in the editions of the Corpus Juris opposite to

the Greek text, and is very valuable, notwithstanding it has been stigmatised by some with the name "barbarous:" it is sometimes called Authentica Interpretatio or Vulgata; a recent and valuable edition is that of G. E. Heimbach, 2 vols. 8vo, Lips. 1846-50. The version of Haloander is also printed in some editions of the Corpus Juris. The Novellæ made many changes in the law as established by Justinian's prior compilations, and are an evidence that the emperor was seized with a passion for legislating; a circumstance which enables us to form a more correct judgment of his real merits, and lowers his character as a philosophic jurist.

[Ludewig, *Vita Justiniani Magni atque Theodoræ, nec non Triboniani*, Halle, 1731; Zimmern, *Geschichte des Römischen Privatrechts bis Justinian*, Heidelberg, 1826; Hugo, *Lehrbuch der Geschichte des Römischen Rechts*, Berlin, 1832; *History of the Roman or Civil Law*, by Ferriere, translated by J. Beaver, London, 1724; Hommelii, *Palingenesia*; Brinkmannus, *Institutiones Juris Romani*, Schleswig, 1822; *System des Pandekten-Rechts*, by Thibaut, 7th ed., Jena, 1828; *Das Corpus Juris in's Deutsche übersetzt von einem vereine Rechtsgelehrter und herausgegeben von Otto, Schilling und Sintenis*, Leipzig, 1831; Irving's *Introduction to the Civil Law*; *Les Cinquante Livres du Digeste*, &c., *Traduits en Français par feu M. Henri Hulot*, Paris, 1805; *Pandectes de Justinien mises dans un nouvel ordre, &c.*, par R. J. Pothier, traduites par Bréard Neuville, révisées et corrigées par M. Moreau de Montalin, Avocat, Paris, 1810; Pothier's edition of the *Digest*, reprinted at Paris, in 5 vols. 4to, 1818-20, is a useful edition; there is a very cheap edition of the *Corpus Juris*, published in Germany, by Beck, 3 vols., small fol., Leipzig, 1829; the editions of the *Corpus Juris* and of the *Institutes* are very numerous.] [CORPUS JURIS; GAJUS, in BIOG. DIV.]

JUVENILE OFFENDERS. Numerous statutes have been passed of late years with the view of providing for the effectual reformation of criminal children; but the law is still in a transitional if not experimental state. Criminal Courts are now however enabled to sentence juvenile criminals to confinement in reformatories, which the magistrates of counties and districts are enabled to provide for this purpose, the parents being compellable, if able, to provide for their maintenance and education. The progress of public opinion and of legislation on this subject of deep interest and of national importance will be found traced in a work recently published by Mr. M. D. Hill, the Recorder of Birmingham, which is devoted to an account of the means to be taken for the repression of crime.

JYAR, in Hebrew יָאָר is the eighth month of the Jewish year. It coincides, when earliest, with our April; but when the year is lengthened by the addition of a thirteenth month, it may be as late as our May. In the present year (1860) it begins on the 23rd of April. We usually pronounce the word *Jyar*, but it should be sounded *Ēar*, curiously like the Greek *ἔαρ*, "the spring," with which some etymologists believe the word to be connected. Josephus, in the eighth book of his 'Antiquities,' c. 3, § 3, writes it *Ἰάρ*. In the two manuscripts containing the old calendar of Heliopolis (Balbek) we find it *Iapap* and *Apap*.

The Jewish almanacs mention several fasts in this month, but they do not appear to be all generally observed: one of three days' duration is set down for the commencement of *Jyar*, to be observed as an expiation by any persons who may have committed excesses during the celebration of the Passover in the preceding month; another, on the 10th, is held in memory of the death of Eli, and of the seizure of the Ark by the Philistines (1 Samuel iv. 18); another is kept for the death of Samuel on the 27th. The festivals in this month are only partially celebrated: one, on the 7th, in commemoration of a second consecration of the Temple by the Maccabees; one, on the 23rd, for the capture of Gaza (1 Macc. xiii. 43), or else for the capture of the tower of Jerusalem (ibid. v. 51); and a third is attributed, on insufficient authority, to the 27th, in memory of the expulsion of the Galilæans (?) by the Maccabees, but this would clash with the fast-day above mentioned, instituted to commemorate the death of the prophet Samuel. It appears from the 6th chapter of the 1st book of Kings, v. 1, that the ancient name of this month was *Zif*; it is called there "the second month," that being its place in the calendar before the commencement of the year was transferred from the spring to the autumn, or from Nisan to Tisri. [BUL.] The name occurs again in the 37th verse. *Jyar* has 29 days only.

K

K has the same sound which **C** has before the vowels *a, o, u*. A reference to that consonant will therefore suffice for the power of the letter; its various forms may be seen in ALPHABET. Although this letter is now superfluous, it was not so when the characters of an alphabet were syllabic in power. Thus the letter *k* appears to have denoted at one time the syllable *ka*, while another character represented *ko*, and so on. Hence in the Greek and Hebrew alphabets the former was called *kappa, kaph*: the latter *koppa, koph*. This accounts for the fact, that in Latin the letter *k* was never used except before the vowel *a*, precisely as *q* is found only before *u*, and the Greek *koppa* only before *o*. Even our own alphabet seems to imply such a limit in the use of this consonant, when it gives it the name *ka*, not *ke*; though the latter name would better agree with *be, ce, de, &c.*

KAKODYL. Synonymous with **CACODYL**.

KAKOPLATYL. [**CACOPLATYL**.]

KAEMPFERIDE. A yellow inodorous crystalline substance contained in the root of the *Galanga* (*Kaempferia Galanga*). It fuses below 212° Fahr. and dissolves in 25 parts of ether at 60°. It consists of—

Carbon	65.3
Hydrogen	4.3
Oxygen	30.4
	100.0

KALEIDOPHONE. [**ACOUSTICS**.]

KALEIDOSCOPE, a name compounded of two Greek words (*καλός* and *σκόπος*), and denoting the exhibition of beautiful forms, is the designation of an optical instrument which was invented by Dr. (now Sir David) Brewster, and patented by him in 1817.

About three years before that time Sir David Brewster, being engaged in making experiments on the polarisation of light by reflection, from plates of glass, observed that when two plates were inclined to one another, and the eye of the spectator was nearly in the produced line of the common section of their planes, the farther extremities of the plates were multiplied by successive reflections so as to exhibit the appearance of a circle divided into sectors, also that the several images of a candle near those extremities were circularly disposed about the centre; and these circumstances suggested to him the construction of an instrument of the kind above named.

It may be observed, however, that the multiplication of the image of an object by successive reflections from mirrors inclined to one another had long before been a subject of investigation in treatises on optics; and both Baptista Porta and Kircher had given descriptions of instruments consisting of mirrors united at two of their edges, which, being opened like two leaves of a book, were capable of multiplying the images of objects. Bradley also, about the year 1717, constructed an instrument consisting of two plates of glass inclined to one another, which being placed on a drawing, with the line of section perpendicular to the paper, exhibited to the eye several images of the figures, disposed by successive reflections about a centre. But the optical investigations alluded to are very remotely connected with the properties of the kaleidoscope; and the application of the latter to objects which may be moveable and situated at any distances from the observer, render Brewster's instrument very different from and far superior to the simple contrivances of Porta, Kircher, and Bradley.

The essential parts of the instrument consist of two plane mirrors of glass, having their posterior surfaces blackened in order to prevent any reflection of light from thence; mirrors of polished metal would, however, be preferable: each mirror is from six to ten inches long, and of a trapezoidal form; the larger end about an inch and a-half long, and the shorter end about three-quarters of an inch; and the two are placed in contact with one another at a long end of each, so as to form a dihedral angle, the like ends being placed together: the object to be viewed is disposed contiguously to the larger ends, and the eye should be near the opposite extremity, but a little above the line of contact. The effects produced by the reflections of the light may be understood from the following considerations:—

Let *A C, B C*, in the first of the figures, be the two extremities of the mirrors on the side farthest from the eye of the observer, which is supposed to be near the opposite extremity of the line of section passing through *c* perpendicularly to the plane of the paper. These lines *A C, B C*, and the sectoral space between them (which in the figure is one-eighth part of a circle), will be visible by rays coming directly to the eye; and, at the same time, rays from the line *A C* falling on the mirror *B C* at a certain angle of incidence will, on being reflected from thence to the eye, give rise to the image *c a* of that line; in like manner rays from the line *B C* falling on the mirror *A C* at an equal

angle of incidence will, after reflection, give rise to the image *c b* of the line. These, with the intermediate rays, produce the first reflected sectors *B C a* and *A C b*. Other rays from the sector *A C b* at the surface

of the mirror *A C* will fall on the mirror *B C*; and, while a portion of them arrive at such angles of incidence as to be reflected to the eye and produce the perception of the sector *a c b'*, another portion of them will be reflected back to the mirror *A C* at such angles of incidence as to be re-reflected to the eye and cause the perception of the sector *a' c b''*. In a similar manner the rays first reflected from *B C a* will, by subsequent reflections, give rise to the perceptions of the sectors *b c a'*, *b' c a''*.

Thus it is easy to perceive that an object, as *M*, on *A C*, with its immediately reflected image *M'*, will give rise to the appearances of similar figures at *m m'*, *m'' m'''*; and an object, as *N*, on *A B*, with its immediately reflected image *N'*, will give rise to the appearances of similar figures at *n n'*, *n'' n'''*: also an object, as *P*, between *A C* and *B C*, will appear by reflection similarly situated in all the other sectors.

If the angle *A C B* be $\frac{1}{m}$ th of four right angles, in which *m* is any term in the series of even numbers 4, 6, 8, 10, &c., the number of sectors will be *m*, and each of them will be equal to *A C B*, while *c Y*, the appearance of the line in which the mirrors meet each other, will, as in the figure, bisect the angle which is opposite to *A C B*; also if *m* be any term in the series of odd numbers 5, 7, 9, &c., the number of sectors will be *m*, and each of them will be equal to *A C B*, while *c Y* will coincide with the line in which the two lowest sectors join one another. It may hence be easily understood that if a flat object placed in the sector *A C B*, with its plane perpendicular to the mirrors, have its bounding-lines similarly situated with respect to *A C* and *B C*, the reflected images will be similar and equal to the original object; and the whole will constitute one symmetrical pattern, whether the value of *m* be odd or even: but if the bounding-lines are not similarly situated with respect to *A C* and *B C*, the reflected images will not, in the two lowest sectors, unite so as to correspond to the images in the other sectors, unless *m* be an even number. The second figure represents a pattern produced by the objects represented in the sector corresponding to *A C B* in the first figure.

In order that the whole pattern in the field of view might possess perfect symmetry about the centre *c*, it would be necessary that the eye should be exactly in the direction of the line in which the glass plates meet one another; but in such a situation the reflected images would not be visible: if the eye were far above the line of meeting, the visible field of view would be sensibly elliptical, and the brightness of the field would be diminished; it follows, therefore, that the eye should be near the smaller ends of the mirrors, and very little above the line of their junction. Again, it may be readily understood that, in order to permit the reflected images of objects to be symmetrically disposed about the centre of the field of view, the object should be exactly in a plane contiguous to the mirrors at the extremities which are farthest from the eye; for the line in which the planes of glass meet each other appearing to pass through the common centre of the visible sectors, if the object were placed on that line of junction, and either between the eye and those extremities or beyond the latter, it is evident, the eye being above the line of meeting, that the apparent or projected place of the object would not coincide with that common centre, but in the former case would appear below, and in the latter above, that centre. The length of the mirrors should be such that the object in the sector *A C B* may be distinctly visible; the eye may, however, if necessary, be assisted by a concave or a convex lens.

The first kaleidoscopes constructed by Sir David Brewster consisted simply of the two mirrors, which were fixed in a cylindrical tube; the objects were pieces of variously coloured glass attached to the farther ends of the mirrors and projecting on the sectoral space *A C B* between

them; or the objects were placed between two plates of very thin glass, and held by the hand or fixed in a cell at the end of the tube. In some cases these plates were moved across the field of view, and in others they were made to turn round upon the axis of the tube. The pieces of coloured glass or other objects which were situated in the sector *ACB* were, by the different reflections, made to appear in all the other sectors; and thus the field of view presented the appearance of an entire object or pattern, all the parts of which were disposed with the most perfect symmetry. By moving the glass plates between which the objects were contained, the pattern was made to vary in form; and pleasing variations in the tints were produced by moving the instrument so that the light of the sky or of a lamp might fall on the objects in different directions. When the objects in the sector *ACB* are confined near its upper part, the images evidently form an annular pattern; and, on placing the two mirrors parallel to one another, the successive reflections of the objects produce one which is rectilinear.

Sir David Brewster subsequently found means to obtain multiplied images of such objects as flowers, trees, and even persons or things in motion. For this purpose he caused the two mirrors to be fixed in a tube as before, but this tube was contained in another from which, like the eye-tube of a telescope, it could be drawn at pleasure towards the eye: at the opposite end of the exterior tube was fixed a glass lens of convenient focal length, by which there were formed images of distant objects at the place of the sector *ACB*. These images thus became objects which being multiplied by successive reflections from the mirrors, produced in the field of view symmetrical patterns of great beauty.

Some kaleidoscopes have been executed in such a manner that the two mirrors may be placed at any required angle with one another, by which means the images in the visible field of view may be varied at pleasure. The instrument is capable also of being constructed so that the multiplied image may be projected on a screen, and thus made visible at one time to many spectators. In order to obtain this end, the rays of light from a powerful lamp are, by means of a lens, made to fall upon the object in *ACB* at the farther extremities of the two mirrors; and at the eye-end of the instrument is placed a lens of such focal length that the rays in each of the emergent pencils may converge at the screen: there will thus be formed on the latter a magnified image of the whole pattern. The tube containing the glass plates is frequently mounted on a stand having a ball-and-socket joint, on which it may be turned in any convenient direction; and the instrument being thus supported, the figures in its field may be easily sketched by a skilful artist, who by means of such an apparatus may be assisted in designing beautiful patterns.

Sir David Brewster's account of his invention is contained in his 'Treatise on the Kaleidoscope,' Edinburgh, 1819, of which a new edition has just been published (1860). Dr. Roget has shown ('Annals of Philosophy,' vol. xi.) that the properties of the instrument may be greatly extended by employing, not only two, but three, and even four plane mirrors, united together at their edges so as to form a hollow prism, or a frustum of a pyramid, the reflecting surfaces being towards the interior. Of these, which are called *Polycentral* kaleidoscopes, the instruments constructed with three plane mirrors appear to produce the most pleasing effects; the mirrors may be disposed so that a section perpendicular to the axis shall be an equilateral triangle, a right-angled isosceles triangle, or a right-angled triangle having its two acute angles equal to 30° and 60° . The first disposition of the mirrors affords regular combinations of images in three different directions which cross each other at angles of 60° and 120° ; and to instruments of this kind Dr. Roget gave the name of *Triascope*. With the second disposition the field is divided into square compartments having the hypotenuse of the triangle for their sides: this is called a *Tetrascope*. The third disposition exhibits a field of view divided into hexagonal compartments; and hence the instrument is designated a *Hexascope*.

KALENDÆ. [KALENDAR.]

KALENDAR, a register or distribution of the year, accommodated to the uses of life, containing the order of days, weeks, months, festivals, &c., as they occur in the course of the year. It is so called from the *Kalendæ*, or *Kalends*, which among the Romans denoted the first day of every month. The kalendar, being of civil institution, varies according to the different distributions of time in different countries. Those which we shall take more particular notice of are, the Roman, the Julian, the Gregorian, and the Reformed kalendar: a slight mention of the others will be sufficient.

Romulus, according to tradition, formed what is deemed the original Roman kalendar, by which the year was divided into ten months only, consisting of an unequal number of days, and began with March. The total number of days was 304. It was however soon discovered that the civil year, as thus constituted, was much shorter than the solar year. Romulus therefore added two intercalary months to every year; but these months were not inserted in the kalendar, nor were any names assigned to them until the following reign. Some Roman antiquarians maintained that the old kalendar continued in use till the time of Tarquinius Priscus.

Numa, in imitation of the Greeks, divided the year into twelve months, according to the course of the moon, consisting in all of 354

days: according to Pliny ('Hist. Nat.,' xxxiv. 7), he afterwards added one day more to make the number odd, which was thought a more fortunate number. But as 10 days, 5 hours, 49 minutes (or rather 48 minutes 58 seconds) were wanting to make the lunar year correspond to the course of the sun, he intercalated every other year an extraordinary month, called *Mensis intercalaris*, or *Mercedonicus*, between the 23rd and 24th of February. This month appears to have consisted alternately of 22 and 23 days during periods of 22 years, the last biennium in the 22 years being entirely passed over. The intercalation of this month was left to the discretion of the pontifices, who, by inserting more or fewer days, used to make the current year longer or shorter, as was most convenient for themselves or their friends; for instance, that a magistrate might sooner or later resign his office, or contractors for the revenue have longer or shorter time to collect the taxes. In consequence of this licence the months were transposed from their proper seasons; the winter months carried back into autumn, and the autumnal into summer. Some critics are of opinion that there is a reference to this confusion in one of Cicero's letters to his friend Atticus (x. 17).

Julius Cæsar, when he had made himself master of the state, resolved to put an end to this disorder, by abolishing the use of the intercalations; and for that purpose (B.C. 47) adjusted the year according to the course of the sun, and assigned to the months the number of days which they still contain. He also added an intercalary day to February every four years. [BISSEXTILE.] To make everything proceed regularly, from the 1st of the ensuing January, he inserted in the current year, besides the intercalary month of 23 days, which fell into it, two extraordinary months between November and December, the one of 33, the other of 34 days; so that this year, which was called the last year of confusion, consisted of 15 months, or 445 days. (Sueton., Vit. J. Cæs., c. 40.) These 67 days were inserted in order to set the year right, which was 67 days in advance of the true time.

All this was effected by the care and skill of Sosigenes, an astronomer of Alexandria, whom Cæsar had brought to Rome for that purpose; and a new kalendar was formed from his arrangement by Flavius, digested according to the order of the Roman festivals, and the old manner of computing the days by kalends, nones, and ides, which was published and authorised by the dictator's edict.

This is the *Julian* or *Solar* year, which continues in use to this day in all Christian countries, without any other variation than that of the *old* and *new style*, which was occasioned by a regulation of Pope Gregory XIII., A.D. 1582, who, observing that the vernal equinox, which at the time of the council of Nice, A.D. 325, had been on the 21st of March, then happened on the 10th, by the advice of astronomers caused ten days to be thrown out of the current year, between the 4th and 15th of October; and to make the civil year for the future to agree with the real one, or with the annual revolution of the earth round the sun, or, as it was then expressed, with the annual motion of the sun in the ecliptic, which is completed in 365 days, 5 hours, 49 minutes, he ordained that every 100th year should not be leap-year, excepting the 400th; so that the difference will hardly amount to a day in 7000 years, or, according to a more accurate computation of the length of the year, to a day in 5200 years.

This alteration of the style was immediately adopted in all Catholic countries; but not in Great Britain till the year 1752, when eleven days were dropped between the 2nd and 14th of September, so that this month contained only nineteen days; and thenceforth the new or reformed style was adopted, as it had been before in most other countries of Europe. The same year also another alteration was made in England, by which the legal year, which before had begun on the 25th of March, began upon the first of January; this alteration first took place on the 1st of January, 1752: see the Statute 24 Geo. II., ch. 23. By this statute it was also enacted that the several years of our Lord 1800, 1900, 2100, 2200, 2300, or any hundredth year of our Lord which shall happen in time to come, except only every fourth hundredth year of our Lord, whereof the year 2000 shall be the first, shall not be deemed bissextile or leap-years, but shall be considered as common years, consisting of 365 days only; and that the years of our Lord 2000, 2400, 2800, and every other fourth hundredth year of our Lord from the year 2000 inclusive, and also all other years of our Lord which, by the present computation, are considered bissextile or leap-years, shall, for the future be esteemed bissextile or leap-years, consisting of 366 days: and that whereas according to the rule then in use for calculating Easter-day, that feast was fixed to the first Sunday after the first full moon next after the 21st of March; and if the full moon happens on a Sunday, then Easter-day is the Sunday after; which rule had been adopted by the general council of Nice; but that as the method of computing the full moons then used in the church of England, and according to which the table to find Easter prefixed to the book of Common Prayer is found, had become erroneous, it was enacted that the said method should be discontinued, and that from and after the 2nd of September, 1752, Easter-day and the other moveable and other feasts were henceforward to be reckoned according to the kalendar tables and rules annexed to the Act, and attached to the books of Common Prayer. This was, in fact, an enactment of the Gregorian alteration, though no allusion to the source of the alteration is made. [EASTER, METHOD OF FINDING.]

It is not generally known that an effort was made to reform the

kalendar in England as early as the reign of Queen Elizabeth. On the 16th of March, 27 Eliz., A.D. 1584-5, a bill was read the first time in the House of Lords, entitled "An Act giving Her Majesty authority to alter and new make a Kalendar according to the Kalendar used in other Countries." It was read a second time on the eighteenth of that month, after which no notice occurs of the proposed measure.

The formation of the *Hebrew* kalendar is fixed by some to the same year as the council of Nice, A.D. 325: others have placed it in the year 360: and others as late as A.D. 500. Lindo however assures us that the Mishna compiled according to the Jewish account in the year A.D. 141, proves that the kalendar as used by the Jews in its present form, with the intercalary month, was generally known and followed at that time.

For further information upon the Jewish kalendar the reader may consult Dr. Adam Clarke's 'Commentary upon the Bible,' and Lindo's 'Jewish Calendar.'

Two Kalendars are in use in the East: the Arabian, which is common to all the Mohammedan countries; and the Persian, the use of which is peculiar to that country. This last is founded on the Persian era called 'Yezdegird.'

Of the three parts into which the Romans divided their month, the *kalendæ*, or *kalends*, have been already explained. They were so called (*à calando vel vocando*), from the pontifex calling out to the people that it was new moon. The fifth day of the month was called *Nonæ*, the nones, and the 13th *Idus*, the ides, from the verb *iduarè*, to divide; because the ides nearly divided the month. The nones, from *nonus*, the ninth, were so called because, counting inclusively, they were nine days from the ides. In March, May, July, and October, the nones fell on the 7th and the ides on the 15th of the month. The mode of fixing any particular day was by saying that it was so many days before the kalends, nones, or ides, next immediately following. Thus the 28th of April was the 4th day before the kalends of March; the 4th of March was the 4th day before the nones of March; and the 9th of March was the 7th day before the ides of March.

The Attic year consisted of twelve lunar months of 30 and 29 days alternately: an intercalary month of 29 or 30 days was inserted every two years, but as this was $7\frac{1}{2}$ days too much, the intercalary month was sometimes omitted. The full Attic month consisted of 30 days, and was divided into three decades.

On the subject of the Greek Kalendar the reader may consult Ideler, 'Handbuch der Mathematischen und Technischen Chronologie.'

(Adams's *Roman Antiquities*; Niebuhr, *On the Secular Cycle, Hist. of Rome*; Brady's *Clavis Calendaria*; Sir Harris Nicolas's *Chronology of History*; Hutton's *Philosophical and Mathematical Dictionary*, v. *Calendar*; Lindo's *Jewish Calendar*, 8vo. Lond. 1838.)

The last we shall mention is the *French Revolutionary Kalendar*. In September, 1793, the French nation resolved that the republic should form a new era, and that a kalendar should be adopted on what were termed philosophical principles. The Convention therefore decreed, on the 24th of November, 1793, that the common era should be abolished in all civil affairs: that the new French era should commence from the foundation of the republic, namely, on the 22nd of September, 1792, on the day of the true autumnal equinox, when the sun entered Libra at 9^h 18^m 30^s in the morning, according to the meridian of Paris; that each year should begin at the midnight of the day on which the true autumnal equinox falls; and that the first year of the French republic had begun on the midnight of the 22nd of September, and terminated on the midnight between the 21st and 22nd of September, 1793. To produce a correspondence between the seasons and the civil year, it was decreed, that the fourth year of the republic should be the first sextile, or leap-year; that a sixth complementary day should be added to it, and that it should terminate the first Franciade; that the sextile or leap-year, which they called an olympic year, should take place every four years, and should mark the close of each Franciade; that the first, second, and third centurial years, namely, 100, 200, and 300 of the republic, should be common, and that the fourth centurial year, namely, 400, should be sextile; and that this should be the case every fourth century until the 40th, which should terminate with a common year. The year was divided into twelve months of thirty days each, with five additional days at the end, which were celebrated as festivals, and which obtained the absurd name of "Sansculottides." Instead of the months being divided into weeks, they consisted of three parts, called Decades, of ten days each. It is however to be observed that the French republicans rarely adopted the decades in dating their letters, or in conversation, but used the number of the day of each month of their kalendar.

The republican kalendar was first used on the 26th of November, 1793, and was discontinued on the 31st of December, 1805, when the Gregorian was resumed.

On examination we find that many works give an account of this kalendar which is more or less incorrect. The decrees of the National Convention, which fixed the new mode of reckoning, were both vague and insufficient, so that it is no wonder that many detailed accounts neither agree with each other nor with the truth. To learn what the truth was, we have recourse to a French work, in its sixth edition: 'Concordance des Calendriers Républicain et Grégorien,' par L. Rondonneau, Paris (6ième édition), 1812, 8vo. This work puts every day of every year, from An II. to An XXII. both inclusive, opposite to its

ARTS AND SCI. DIV. VOL. V.

day of the Gregorian kalendar; it also gives the decrees of the National Convention. The account we have already given is stated in the common way: we leave it for the reader to compare with the more accurate version.

By these decrees it appears that the year is to begin at the midnight of Paris Observatory which precedes the true autumnal equinox. It is to consist of 365 days, with 12 months of 30 days each (the 30 days being 3 decades of 10 days each), and 5 complementary days, which were tastefully called *sansculottides* (a name afterwards repealed). A sixth complementary day was to be added, not according to any rule, but *selon que la position de l'équinoxe le comporte*; and although it was stated that it would be *ordinairement nécessaire* to add this 366th day once in four years, yet it is not even stated in what particular coming years the necessity would arise. The first decree, dated October 5, 1793 (the new month not having been introduced), declares the year then current to be the second year of the French republic, and enacts that An I. began with September 22, 1792, and An II. with September 22, 1793. The second decree, fixing the months, is dated the 4th of Frimaire, An II. (November 24th, 1793). The Gregorian reckoning was restored from and after January 1, 1806, by an imperial ordonnance, dated 22 Fructidor, An XIII. (September 9, 1805).

It is to actual usage, then, that we must appeal to know what the decrees do not prescribe—namely, the position of the leap-years. For though every period of four years was a *Franciad*, and the last year of the Franciad was called *Sextile* (having six complementary days), yet, in fact, An IV., An VIII., &c., are not leap-years. The following list, actually made from the work above mentioned, must be used as a correction of the usual accounts. For various matters connected with the public debt, &c., it was necessary to construct the table up to An XXII.

		Sept.			Sept.
An I.	begins	22, 1792	An XII.	begins	24, 1803
II.	"	22, 1793	XIII.	"	23, 1804
Sext. III.	"	22, 1794	XIV.	"	23, 1805
IV.	"	23, 1795	Sext. XV.	"	23, 1806

Sext. XI.	"	23, 1802	XXII.	"	23, 1813

When the Gregorian year is not leap-year the beginnings of the months are as follows, according as the republican year begins on September 22, 23, or 34:—

1	Vendémiaire	is	Sept.	22, 23, 24
1	Brumaire	is	Oct.	22, 23, 24
1	Frimaire	is	Nov.	21, 22, 23
1	Nivose	is	Dec.	21, 22, 23
1	Pluviose	is	Jan.	20, 21, 22
1	Ventose	is	Feb.	19, 20, 21
1	Germinal	is	March	21, 22, 23
1	Floréal	is	April	20, 21, 22
1	Prairial	is	May	20, 21, 22
1	Messidor	is	June	19, 20, 21
1	Thermidor	is	July	19, 20, 21
1	Fructidor	is	Aug.	18, 19, 20

1	Jan.	is	Niv.	12, 11, 10
1	Feb.	is	Pluv.	13, 12, 11
1	March	is	Vent.	11, 10, 9
1	April	is	Germ.	12, 11, 10
1	May	is	Flor.	12, 11, 10
1	June	is	Prair.	13, 12, 11
1	July	is	Messid.	13, 12, 11
1	Aug.	is	Thermid.	14, 13, 12
1	Sept.	is	Fructid.	15, 14, 13
1	Oct.	is	Vendém.	10, 9, 8
1	Nov.	is	Brum.	11, 10, 9
1	Dec.	is	Frim.	11, 10, 9

But when the Gregorian year is leap-year the beginnings of the months are as follows, according as the republican year begins on September 22, 23, or 24:—

1	Vendém.	is	Sept.	22, 23, 24
1	Brum.	is	Oct.	22, 23, 24
1	Frim.	is	Nov.	21, 22, 23
1	Niv.	is	Dec.	21, 22, 23
1	Pluv.	is	Jan.	20, 21, 22
1	Vent.	is	Feb.	19, 20, 21
1	Germ.	is	March	20, 21, 22
1	Flor.	is	April	19, 20, 21
1	Prair.	is	May	19, 20, 21
1	Messid.	is	June	18, 19, 20
1	Thermid.	is	July	18, 19, 20
1	Fructid.	is	Aug.	17, 18, 19

1	Jan.	is	Niv.	12, 11, 10
1	Feb.	is	Pluv.	13, 12, 11
1	March	is	Vent.	12, 11, 10
1	April	is	Germ.	13, 12, 11

1	May	is	Flor.	13, 12, 11
1	June	is	Prair.	14, 13, 12
1	July	is	Messid.	14, 13, 12
1	Aug.	is	Thermid.	15, 14, 13
1	Sept.	is	Fructid.	16, 15, 14
1	Oct.	is	Vendém.	11, 10, 9
1	Nov.	is	Brum.	12, 11, 10
1	Dec.	is	Frim.	12, 11, 10

For instance, what is 14 Floréal, An XII.? The republican year begins Sept. 24, 1803, so Floréal falls in 1804, which is Gregorian leap-year. Look at the third table, and when the year begins Sept. 24, the 1st of Floréal is April 21; consequently the 14th is May 4, 1804. Again, what is June 17, 1800, in the French calendar? The year is not Gregorian leap-year; and An VIII. contains it, which begins Sept. 23. Look in the second table, and in such a year it appears that June 1 is the 12th of Prairial; therefore June 17 is Prairial 28.

KALENDS. [KALENDAR.]

KALIF. [CALIPH.]

KALISACCHARIC ACID. Synonymous with GLUCIC ACID.

KAPNOMOR. [CAPNOMOR.]

KEEPER, LORD. [LORD KEEPER.]

KELP. [IODINE.]

KERMES MINERAL. [ANTIMONY.]

KERSEY, KERSEYMERE. [WOOLLEN MANUFACTURES.]

KETONES. This name is applied in organic chemistry to a class of bodies obtained by submitting certain salts of the fatty acids, such as acetic acid, to dry distillation. Acetone is one of the best known ketones, and the mode of its formation will represent that of the rest of these bodies. It is best produced by distilling acetate of lime, when the following reaction occurs:

Various views of the constitution of the ketones have been entertained by chemists, but the one now almost universally held regards them as compounds of a negative with a positive organic radical. Thus according to this view, acetone is written as methide of ethyl:

In all the ketones hitherto known, the positive radical always contains two equivalents of carbon less than the negative, but it is not improbable that ketones may be formed in which this relation between the radicals will not obtain.

The ketones may thus be regarded as aldehydes, in which the single equivalent of hydrogen is replaced by a compound positive radical; thus—

The following are the principal ketones at present known:—

Acetone		$\text{C}_6\text{H}_6\text{O}_2$
Propione		$\text{C}_{10}\text{H}_{10}\text{O}_2$
Butyrone		$\text{C}_{14}\text{H}_{14}\text{O}_2$
Valerone		$\text{C}_{18}\text{H}_{18}\text{O}_2$

The ketones, as a class, have hitherto been very incompletely studied.

KEY, in music, is the particular diatonic scale, whether major or minor, in which a composition begins and ends, and which more or less prevails in a given piece of music.

The diatonic scale may commence on any note, and that chosen—called the *Key-Note*—governs the progression of the other notes. [SCALE; DIATONIC.] If a composition begins and ends in a scale in which neither sharps nor flats are used, it is in the key of C, the distinctive term *natural* being understood. When three flats are placed at the clef, and the last and lowest note in the piece is E♭, the key is E♭. If in such case the last and lowest note is C, the key is C minor, &c.

As any note in the diatonic and chromatic scales may be taken as a key-note, it follows that there are twelve keys in the major mode, and twelve in the minor; for each scale may have either a major or a minor 3rd. [MAJOR; MINOR.] Hence arise twenty-four keys. But as three major and consequently three minor keys are binominous, there are in name thirty different keys, and as many signatures are in actual use [SIGNATURE]; though, in fact, there is only the before-mentioned number of keys differing in reality.

TABLE OF MAJOR KEYS.

F# (same as G♭). C# (same as D♭).

F. B♭. E♭. A♭.

D♭ (same as C#). G♭ (same as F#). C♭ (same as B).

TABLE OF MINOR KEYS.

A minor. E minor. B minor.

F# minor. C# minor. G# min. (same as A♭ min.)

D# min. (same as E♭ min.) A# min. (same as B♭ min.)

D minor. G minor. C minor. F minor.

B♭ min. (same as A# min.) E♭ min. (same as D# min.) A♭ min. (same as G# min.)

By admitting double sharps and flats, the number of keys may be much farther, but not usefully, extended.

KHAN, a word of Mongol or Turkish extraction, said to mean "great and powerful lord," was employed by the nations of Central Asia to express the full extent of royal power. This title was assumed by Gengis when he became supreme ruler of the Mongols and Tartars, and was adopted by all his successors. The earlier monarchs of the Ottoman empire were also distinguished by this title. The word is used in Persia in a much more restricted sense, and is applied to the governors of provinces, and to all officers of a certain rank.

The original form of this word was *Khaghan*; Gengis Khan is always called *Jinggis Khaghan* in the Mongol language.

KIDNAPPING is defined to be the stealing or conveying away of a man, woman, or child, and is an offence at common law, punishable by fine and imprisonment, and, formerly, by pillory. The highest form of this offence, the forcibly sending a man from his own country into some other, or to parts beyond the seas, though at common law only punishable as above mentioned, is an offence, as has been remarked, of such primary magnitude that it might well have been substituted upon the roll of capital crimes, in the place of many others, which until recently were there to be found (1 East's Pleas of the Crown, c. ix., s. iv.).

The Jewish law declared that "he that stealeth a man, and selleth him, or if he be found in his hand, he shall surely be put to death" (Exod. xxi., 16). And by the civil law, the offence of spiriting away and stealing men and children, was punished with death. Magna Charta, the petition of right, and the habeas corpus acts are pointed to the security from expatriation, as are also the numerous legislative provisions and treaties for the suppression of the slave trade.

The forcible impressment of seamen for the royal navy is an odious exception to the right of the subject, in this country, to his personal liberty, when not charged with any crime, and is limited by various statutes, and the wrongful carrying off and leaving behind seamen, for private purposes, is punishable by imprisonment (see 17 & 18 Vict., c. 104).

The general remedy for the unlawful detention of persons is by application to the courts of law for a writ of habeas corpus. The rights of parents and guardians and others to the custody of children, alleged to have been wrongfully taken away or detained for the purposes of education or otherwise are in this way frequently discussed and decided.

The 9 Geo. IV., c. 21, which is directed against child-stealing, enacts that if any person shall maliciously, by force or fraud, lead, or take away, or decoy or entice away, or detain, a child under the age of ten years, with intent to deprive its parents, or any other person having the lawful care of such child, of the possession of it, or with intent to steal any article upon or about the person of such child, to whomsoever such article may belong, or shall receive and harbour with any such intent as aforesaid any such child, knowing that it has been by force or fraud led, taken, decoyed, enticed away, or detained, every such offender, and their counsellors, procurers, aiders, and abettors, shall be guilty of felony, and shall be liable to be transported for seven years, or to be imprisoned, with or without hard labour, in the common gaol or house of correction, for any time not

exceeding two years; and if a male, to be once, twice, or thrice publicly or privately whipped (if the court shall so think fit) in addition to such imprisonment.

The act does not extend to a person who shall have claimed to be the father of an illegitimate child, or to have any right to the possession of such a child, on account of his getting possession of such child, or taking it out of the possession of the child's mother, or other person who has the lawful charge of it. The Irish act (10 Geo. IV., c. 34) is in precisely similar terms. (Kerr's Blackstone and Russell on Crimes by Greaves.)

As to the conveying away of heiresses and young women, see ABDUCTION.

KIDNEYS, DISEASES OF. The principal disease to which the kidneys are liable is that which gives rise to the formation of calculi. [CALCULUS.] Sometimes the stone is retained in the pelvis of the kidney, where, by continued depositions, it may increase till it completely fills the pelvis and calyces; but more frequently it passes through the ureters into the bladder, producing in its passage violent spasmodic pain in the loins, sickness and nausea, hæmorrhage, &c. This affection is the most common cause of inflammation of the kidneys (nephritis), from which abscess and other morbid alterations may result.

An affection of the kidneys, having very definite symptoms, and exhibiting uniformity of structural change, was first pointed out by Dr. Bright of Guy's Hospital, and is generally called after him. This disease is also called *Albuminuria* and *granular disease of the kidney*; the first on account of its diagnostic symptom, albumen in the urine, the second on account of the morbid condition presented by the kidney. This formidable disease presents several stages or varieties, and some discussion has taken place as to whether the symptom of albumen in the urine may not occur in several distinct morbid conditions of the kidney. There is no doubt that albumen may be found in the urine in even functional derangements of the kidney; but the term Bright's Disease is very conveniently applied to all those forms of structural change in the kidney which are accompanied with albuminous urine.

The great symptoms accompanying this disease vary according to the intensity of the disease and the condition of the patient. One of the first symptoms to which the physician's attention is usually drawn, is the presence of dropsy. This may occur in the skin or in any of the cavities of the body. It is frequently noticed in the face; and in all varieties of this disease an effusion of fluid is observed underneath the conjunctiva, producing the appearance of a watery eye. In addition to dropsical effusions, inflammatory affections of the mucous and serous membranes are very common accompaniments of Bright's Disease. The heart also is frequently affected, and pericarditis and endocarditis are observed. Affections of the brain are also not unfrequently present, especially in the more severe cases arising from the poisoned condition of the blood.

In all cases of this disease, the urine contains albumen. This is easily detected either by coagulating the albumen by heat or nitric acid. The specific gravity of the urine is also decreased, being sometimes as low as 1.010, whilst healthy urine has a specific gravity of 1.020. It contains less urea than healthy urine. Under the microscope it also presents appearances indicative of the nature of the disease. These appearances consist of casts of the minute tubes of the kidneys, formed by substances produced in various stages of the disease. They are thus classified by Dr. Bennett:—

1. *Exudative casts*, consisting of the coagulated exudation or fibrin which is poured into the tube during the inflammatory stage.
2. *Desquamative casts*, consisting of masses of the epithelium lining the tubes, and occurring in all stages of the disease.
3. *Fatty casts*, consisting of patches of epithelium as in the last, but which have undergone a fatty transformation by the accumulation of a greater or less number of fatty granules in its cells.
4. *Waxy casts*, presenting an exceedingly diaphanous and structureless substance. They are frequently associated with the two last.

Dr. Bright originally described three stages of this disease, but later observers have recognised six.

1. The catarrhal form, in which the kidneys are enlarged, and contain an increased quantity of blood. In this stage only a small quantity of urine is passed, containing the exudative and desquamative casts.
2. In this stage the kidney is enlarged to nearly double its size and is white and granular in its appearance. The tubes of the kidney are obliterated by the inflammatory deposit. The urine is very albuminous, and of light specific gravity.
3. The kidney presents a mottled appearance. It is probably a transition from the first to the second stage.
4. In this stage the kidney is large, dense, and white. The tissues of the kidney have become charged. The urine is scanty, of low specific gravity, and defective in urea and other excretory matters.
5. In this stage the kidney is hard, granular, and contracted. The kidney is smaller than in health, the surface is uneven and puckered, the tunic adherent. There is no deposit in the tubes, but fibrous matter has been deposited in the tissues of the kidney, and the tubes are strangulated. The urine may not contain albumen. Its specific gravity is sometimes as low as 1.005.
6. This stage has been called the 'coarse kidney.' The organ is

large and dark. The specific gravity of the urine is high, and it is loaded with urates.

The presence of fatty matter in the casts of the kidneys may occur in any of these stages, and does not appear to exist as a separate form of the disease.

The cause of this disease is anything which will unduly excite the action of the kidney. Thus it comes on as the result of spirit drinking, which powerfully excites the action of the kidneys. Exposure to cold and diminution of the action of the skin will also produce it. It comes on frequently after scarlatina, when the skin is highly susceptible of any diminution of temperature.

The treatment must be active in the early stages. Purgatives may be given and blood abstracted locally, and the febrile symptoms treated accordingly. Mercury is not found beneficial. When chronic, diaphoretics and diuretics are both admissible. Amongst the former, Dover's powder and warm baths, and the latter, bitartrate of potash and digitalis. The patient should be protected from cold; a warm climate is serviceable; and a nutritious but not stimulating diet, with fresh air and exercise, are desirable.

The name of Dr. Addison, physician to Guy's Hospital, has been connected with a diseased condition of the system, which is made apparent by a discoloration of the skin. Hence this disease is also called 'Bronzed Skin.' The existence of this discoloured skin has long been known as a symptom of certain cachectic states of the system; but Dr. Addison was the first to point out that this state of the skin generally existed in connection with a diseased condition of the supra-renal capsules. These bodies belong to the class of ductless glands, and till the time of Dr. Addison's researches upon bronzed skin appeared, little was known of their uses and functions in the human body. The following conclusions with regard to these bodies have been arrived at by Dr. Harley as the result of his experiments:—

1. The supra-renal capsules are not solely foetal organs.
2. They are not absolutely essential to life.
3. The removal of the right is generally more fatal than the left.
4. That convulsions do not necessarily follow their removal.
5. The absence of their function is attended neither by great emaciation nor debility.
6. If death follows an experiment, it occurs as the result of injuring neighbouring parts.
7. Absence of the supra-renal bodies is not proved to have any special effect in arresting the transformation of hæmatin, or in increasing the formation of blood crystals.
8. The suppression of the supra-renal capsular function is not attended by an increased deposit of pigment in the skin or its appendages.
9. The problem of the connection of the bronzed skin and supra-renal capsular disease is more likely to be solved in the dead-house than in the physiological laboratory.

These conclusions were chiefly arrived at by experiments on rats, but they would seem to indicate that the connection between the bronzed skin and supra-renal capsules is not clearly made out.

The distinguishing features of the disease to which the name bronzed skin has been given, are general languor and debility, great feebleness of the heart's action, irritability of the stomach, a peculiar change of colour of the skin, and these symptoms usually occurring in connection with a diseased condition of the supra-renal capsules. The general symptoms are in fact those of anæmia, or cases in which the blood is imperfectly developed. Dr. Addison says of this discoloration of the skin, that it usually increases with the advance of the disease. "The anæmia, languor, failure of appetite, and feebleness of the heart become aggravated; a darkish streak usually appears upon the commissure of the lips; the body wastes, but without the extreme emaciation and dry harsh condition of the surface so commonly observed in ordinary malignant diseases; the pulse becomes smaller and weaker, and without any special complaint of pain or uneasiness, the patient at length gradually sinks and expires. In one case, which may be said to have been acute in its development as well as rapid in its course, and in which both capsules were found universally diseased after death, the mottled or checkered discoloration was very manifest, the anæmic condition strongly marked, and the sickness and vomiting urgent; but the pulse, instead of being small and feeble as usual, was large, soft, extremely compressible, and jerking on the slightest exertion or emotion, and the patient speedily died." (Addison.)

Although the connection between the state of the skin and the disease of the capsules was exhibited in all Dr. Addison's original cases, many exceptions have been recorded. Cases have occurred in which extensive disease of the supra-renal capsules has occurred without any bronzed skin, and cases of bronzed skin have been seen where no disease of the supra-renal capsules could be detected after death.

Dr. Harley, in the paper before referred to, concludes:—

1. That bronzed skin may exist without the supra-renal capsules being diseased.
2. That complete degeneration or total absence of the supra-renal capsules may occur without any bronzing of the skin.
3. That bronzed skin may be associated with a variety of differently marked conditions of the system, among which a prominent one is disease of the supra-renal capsules.
4. That bronzed skin may be present without any derangement of

the other functions of the body being observed. ('British and Foreign Medico-Chirurgical Review,' No. 42, 1848.)

Dr. Harley is of opinion that the general symptoms of this disease are produced by a "diseased state of the solar plexus *per se*, or by irritation of the ganglionic system of nerves, caused by the close proximity and intimate connection of diseased supra-renal capsules."

The blood has been examined by the microscope in some of these cases, and found to present an increased quantity of the white blood cells, as observed in the disease known as Leucocythemia. [BLOOD, DISEASES OF.]

The microscopic character of the skin has been carefully examined in this disease, and it has been found to present the same appearance as observed in the skin of the black man. The pigmentary matter of the skin was found to be increased, and existed in larger quantities in the under than in the upper layers of the epidermis.

The treatment of this disease is not affected by our knowledge of its supposed cause. The remedies which would be applicable to bloodless and depressed conditions of the system, should be used here. Tonics, nutritious diet, fresh air, and the means resorted to for restoring health in anæmia and leucocythemia may be had recourse to here.

The prognosis in this disease is unfavourable, although cases are reported in which recovery has taken place.

Suppression of urine may be the ultimate result of obstruction from calculi in the ureters, or it may occur as an idiopathic disease. It is a condition of great danger, for low delirium and a comatose sleepy state very often supervene on it, and soon terminate fatally. Long and often repeated attacks of retention of urine from obstruction produce dilatation of the ureters and pelvis, which sometimes acquire an enormous size. There may result from the same cause a gradual absorption of the substance of the kidney, till in an advanced stage there is found nothing but a thin sac containing urine in a single cavity, or in a number of separate pouches. The kidneys are also subject, in common with other organs, to the deposition of various morbid substances, as cancer, fungus, hæmatodes, melanosis, tubercle, &c. But the diagnosis of all the chronic affections of this organ is extremely obscure, the principal indications of each being the same, viz., the dull heavy pain in the loins, dropsy, and sometimes hæmaturia.

KIN. [DESCENT; INTESTACY.]

KING. The primary use of this word is to denote a person in whom is vested the higher executive functions in an independent state, together with a share, more or less limited, of the sovereign power. The state may consist of a vast assemblage of persons, like the French or the Spanish nation, or the British people, in which several nations are included; or it may be small, like the Danes, or like one of the states while in England there were seven states independent of each other; yet if the chief executive functions are vested in some one person who has also a share in the sovereign power, the idea represented by the word *king* seems to be complete. It is even used for those chiefs of savage tribes who are a *state* only in a certain loose and colloquial sense of the term.

It signifies nothing whether the power of such a person be limited only by his own conscience and will, or whether his power be limited by certain immemorial usages and written laws, or in any other way; still such a person is a king.

Nor does it signify whether he succeed to the *throne*, the seat on which he sits when in the exercise of his royal authority, by descent and inheritance on the death of his predecessor, just as the eldest son of a peer succeeds to his father's rank and title on the death of the parent, or is elected to fill the office by some council or body of persons selected out of the nation he is to govern, or by the suffrages of the whole nation. Thus there was a king of Poland who was an elected king; a king of England who succeeded by hereditary right.

Still, in countries where the kingly office is hereditary, some form has always been gone through on the accession of a new king, in which there was a recognition on the part of the people of his right, a claim from them that he should pledge himself to the performance of certain duties, and generally a religious ceremony performed, in which anointing him with oil and placing a crown upon his head were conspicuous acts. By this last act is symbolised his supremacy; and by the anointing a certain sacredness is thrown around his person. These kinds of ceremonies, we believe, are found in all countries in which the sovereign, or the person sharing in the sovereign power, is known as king; and these ceremonies seem to make a distinction between the succession of an hereditary king to his throne and the succession of an hereditary peer to his rank.

The distinction between a king and an emperor is not very clearly defined. *Emperor* comes from *imperator*, a title used by the sovereigns of the Roman empire. When that empire became divided, each sovereign, that of the West and that of the East, called himself an emperor. These emperors claimed a kind of supremacy over other sovereigns. The emperor of Germany was regarded as a kind of successor to the emperors of the West, and the emperor of Russia (who was and is often called the Czar), is, with less pretension to the honour, sometimes spoken of as successor to the emperor of the East. But we speak of the emperor of China, where emperor is clearly nothing more than king, and we use emperor rather than king only out of regard to the vast extent of his dominions. Napoleon I. called himself an emperor,

a title revived by his nephew Napoleon III.; and we sometimes speak of the British empire. [EMPEROR.]

The word *king* is of pure Teutonic origin, and is found slightly varied in its literal elements in most of the languages which are sprung from the Teutonic. The French, the Italian, the Spanish, and the Portuguese, on the other hand, have chosen to continue the use of the Latin word *rex*, only slightly varying the orthography according to the analogies of each particular language. *King*, traced to its origin, seems to denote one to whom superior knowledge has given superior power, allied, as it seems to be, to *know*, *con*, *can*; but on the etymology, or what is the same thing, the remote origin of the word, different opinions have been held, and the question may still be considered undetermined.

There are two or three other words employed to designate the sovereigns of particular states, in using which we adopt the word which the people of those states use, instead of the word *king*. Thus there is the *Shah* of Persia, the *Elector* of Hesse-Cassel, the *Czar* (now more commonly styled Emperor) of Russia, and the grand *Sultan*. In the United States of America very limited powers are given to one person, who is elected to enjoy them for a short period with the title of *President*. A *Regent* is a temporary king.

A personage in whom such extraordinary powers have been vested must of necessity have had very much to do with the progress and welfare of particular nations, and with the progress of human society at large. When held by a person of a tyrannical turn of mind, these powers might be made use of to repress all that was great and generous in the masses who were governed, and to introduce among them all the evils and miseries of slavery. Possessed by a person of an ambitious spirit, they might introduce unnecessary quarrelling among nations to open the way for conquest, so that whole nations might suffer for the gratification of the personal ambition of one. The lover of peace and truth, and human improvement and security, may have found in the possession of kingly power the means of benefiting a people to an extent that might satisfy the most benevolent heart. But it must now by the long experience of mankind have become sufficiently apparent that for the king himself and for his people it is best that there should be strong checks in the frame of society on the mere personal and private disposition of kings, in the forms of courts of justice, councils, parliaments, and other bodies or single persons whose concurrence must be obtained before anything is undertaken in which the interests of the community are extensively involved. In most countries, as in England, there are controlling powers such as these, and even in countries in which the executive and legislative power are nominally in some one person absolutely, the acts of that person are virtually controlled, if by nothing else, by the opinion of the people, a power constantly increasing as the facilities of communication and the knowledge of a people advance.

Nothing can be more various than the constitutional checks in different states on the kingly power, or, as it is more usually called in England, the royal *prerogative*. Such a subject must be passed over in an article of confined limits such as this must be, else in speaking of the kingly dignity it might have been proper to exhibit how diversely power is distributed in different states, each having at its head a king. But the subject must not be dismissed without a few observations on the kingly office (now by hereditary descent discharged by a queen) [QUEEN], as it exists among ourselves.

The dawn of the English kingly power is to be perceived in the establishment of Egbert, at the close of the 8th century, as king of the English. His family is illustrated by the talents and virtues of Alfred, and the peacefulness and piety of Edward. On his death there ensued a struggle for the succession between the representative of the Danish kings, who for awhile had usurped upon the posterity of Egbert, and William then duke of Normandy. It ended with the success of William.

This is generally regarded as a kind of new beginning of the race of English kings, for William was but remotely allied to any of the Saxon kings. In his descendants the kingly office has ever since continued; but though the English throne is hereditary, it is not hereditary in a sense perfectly absolute, nor does it seem to have been ever so considered. For when Henry I. was dead, leaving only a daughter, named Maud, she did not succeed to the throne; and when Stephen died, his son did not succeed, but the crown passed to the son of Maud. Again, on the death of Richard I. a younger brother succeeded, to the exclusion of the son and daughter of an elder brother deceased. Then ensued a long series of regular and undisputed successions; but when Richard II. was deposed, the crown passed to his cousin Henry of Lancaster, son of John of Gaunt, son of Edward III., though there were descendants living of Lionel, duke of Clarence, who was older than John among the children of Edward III. When the rule of Henry VI. became weak, the issue of Lionel advanced their claim. The struggle was long and bloody. It ended in a kind of compromise, the chief of the Lancastrian party taking to wife the heiress of the Yorkists. From that marriage have sprung all the later sovereigns, and the principle of hereditary succession remained undisturbed till the reign of King William III., who was called to the throne on the abdication of James II., when an act was passed excluding the male issue of James, the issue of his sister the duchess of Orleans, and the issue of his aunt the queen of Bohemia, with the

exception of her youngest daughter the princess Sophia and her issue, who were Protestants. On the death of Queen Anne this law of the succession took effect in favour of King George I., son of the Princess Sophia.

Now the heir succeeds to the throne immediately on the decease of his predecessor, so that the king, as the phrase is, never dies. But it is supposed that anciently there was a short intermission, and that the whole of the royal power was not possessed till there had been some kind of recognition on the part of the people.

At the coronation of the king he makes oath to three things:—that he will govern according to law; that he will cause justice to be administered; and that he will maintain the Protestant church.

His person is sacred. He cannot by any process of law be called to account for any of his acts. His concurrence is necessary to every legislative enactment. He sends embassies, makes treaties, and even enters into wars without any previous consultation with parliament. He nominates the judges and the other high officers of state, the officers of the army and navy, the governors of colonies and dependencies, the bishops, deans, and some other dignitaries of the church. He calls parliament together, and can at his pleasure prorogue or dissolve it. He is the fountain of honour: all hereditary titles are derived from his grant. He can also grant privileges of an inferior kind, such as rights of exclusive trading, and of markets and fairs.

This is but a very slight sketch of the power inherent in the kings of England; but the exercise of any or all of these powers is limited by two circumstances: first, the king cannot act politically without an agent, and this agent is not protected by that irresponsibility which belongs to the king himself, but may be brought to account for his acts if he transgress the law; and, secondly, the constant necessity which arises of applying to parliament for supplies of money gives to that body virtually such a control over the exercise of the royal prerogative, as amounts to a necessity of obtaining its concurrence in any public measure of importance. [PARLIAMENT.]

KING'S BLUE. [COLOURING MATTERS.]

KING'S EVIL. [SCROFULA.]

KING'S YELLOW. [COLOURING MATTERS.]

KINGS, THE BOOKS OF, the name of two books of the Old Testament. They originally formed only one book in the Hebrew

text, and are entitled מלכים, that is, 'kings.' In the Septuagint they are divided into two books, and are entitled 'the third and fourth books of reigns' or kingdoms (βασιλειῶν τρίτη καὶ τετάρτη); since the first and second books of Samuel are called in this translation the first and second books of Kings.

These books contain an account of Jewish history from the death of David to that of Solomon (1 Kings, i.-xi.); an account of the division of the kingdom under his successor Rehoboam, and the history of the two kingdoms of Israel and Judah, to the conquest of the former by the Assyrians under Shalmaneser (1 Kings, xii.—2 Kings, xvii.); and the separate history of the tribes of Judah and Benjamin, till they were carried away captive to Babylon by Nebuchadnezzar in the reign of Jehoiachin. (2 Kings, xviii.-xxv.) The period covered by the two books is 455 years.

These books, in common with the books of Chronicles and many others of the Old Testament, are generally ascribed to Ezra, though the Jews give the authorship to Jeremiah or Isaiah, but neither the author nor the time in which they were written can be determined with any degree of certainty; and Biblical scholars are much divided in opinion on the subject. It is evident from many passages, and especially from the last chapter of these books, that a portion of them must have been written in the time of the Babylonian captivity; but there are also other passages which must have been written before the destruction of the kingdom of Israel, and while the temple at Jerusalem was still standing. (1 Kings, viii. 8; ix. 13, 21; x. 12; xii. 19; 2 Kings, viii. 22; x. 27; xiv. 7; xvii. 23, 34, 41.) It is therefore probable that these books are only a collection of different documents written by persons present at the events narrated, and that the compiler only wrote such portions as were necessary to connect the different documents, and to form one continuous narrative.

But though there may be uncertainty as to the writer, there is none as to the truth of the matters they record, of which the internal evidence is sufficient proof, independent of which other parts of the sacred writings bear testimony to their integrity, as Matt. xii. 42; Romans, xi. 4, &c., and our Lord, in Luke iv. 26, quotes the example of Elijah and Elisha that prophets have no honour in their own country. The Jews have uniformly accepted these writings as divinely inspired, and Christians as uniformly placed them among the canonical books.

KINIC or QUINIC ACID ($C_{25}H_{20}O_{20} \cdot 2HO$) is obtained from cinchona bark, in the manufacture of sulphate of quinine. It occurs in the bark united with the quinine, and when lime is added to a solution of bark, a kinate of lime is formed. The kinic acid is procured from this compound by the action of oxalic acid. It forms salts with the metals, highly interesting to the chemist.

Kinic acid has a very sour, but when pure not a bitter taste; it reddens litmus paper strongly; is unalterable in the air, dissolves in $2\frac{1}{2}$ times its weight of water at 48° , and is also soluble in alcohol. When heated in a retort it readily fuses, boils up, decomposes, blackens,

and yields an empyreumatic oil, with pungent vapours of *pyrokinic acid*, one portion of which condenses into a liquid, and another crystallises. Sulphuric acid renders kinic acid first green, and then carbonises it; by the addition of a small portion of nitric acid it is converted into an acid resembling the pyrokinic acid, which may be sublimed; but a large quantity of nitric acid changes it into oxalic acid.

The natural kinates, except that of lime already mentioned, are only obtained by complicated processes from the bark; but by artificial means they are readily procured, either by saturating the acid with the bases, or by the double decomposition of kinate of baryta and the sulphates of such bases as form soluble sulphates. We shall describe only a few kinates, and chiefly those which exist in the cinchona, and first we shall notice the most important of them, the

Kinate of Quinine.—The natural salt crystallises with difficulty, on account of the admixture of yellow colouring and other matters, and these have prevented the determination of its crystalline form. This salt is very bitter, readily soluble in water, and but slightly so in alcohol of sp. gr. 0.837. It is decomposable by heat, without residue. By evaporation the solution is reduced to a viscid paste, which, when moistened and exposed to the air, exhibits rudiments of crystallisation. It is, like other salts of quinine, decomposed by the alkalies ammonia, potash, and soda, which precipitate the quinine. Kinate of quinine may be formed artificially by dissolving quinine recently precipitated from the sulphate in a solution of kinic acid, with a gentle heat. By exposure to the air the liquid becomes a mammellated mass, containing small brilliant rhombic crystals of kinate of quinine.

Kinate of Cinchonine.—The natural compound very much resembles that of quinine; the artificial salt yields crystals by exposure to the air, which are like, but are more distinct than, those of the kinate of quinine obtained in the same way. This salt is bitter, very soluble in water, and slightly so in alcohol of sp. gr. 0.837.

Kinate of Lime ($C_{25}H_{20}CaO_{22} + 20 \text{ aq.}$)—This salt crystallises in rhomboids and hexagonal plates; it has but little taste; it is soluble in six times its weight of water at 60° , and much more so in boiling water. It is insoluble in alcohol. It is decomposed by oxalic acid and sulphuric acid, and also by the alkaline carbonates. According to Berzelius, a small quantity of kinate of lime may be obtained from the alburnum of the fir-tree.

The properties of the artificial kinates are thus, with slight alterations, given by Berzelius. *Kinate of potash*, bitter and deliquescent. *Kinate of soda* crystallises in hexahedral prisms; it appears to contain no water of crystallisation, and does not alter by exposure to the air. *Kinate of ammonia*, deliquescent. By evaporation a portion of its acid is set free. *Kinate of baryta* crystallises in dodecahedrons with triangular faces; becomes opaque by exposure to the air; is very soluble in water, but slightly so in alcohol of 0.830. *Kinate of magnesia*, very soluble, and forms crystalline excrescences similar to cauliflowers. *Kinate of manganese* crystallises in rose-coloured lamellar crystals. *Kinate of zinc* crystallises in laminae, or in cauliflower-like aggregations. *Kinate of nickel*, a green gummy mass, very soluble in water. *Perkinate of iron*, a reddish-yellow gummy mass, soluble in water. *Kinate of lead* crystallises in slender needles, which do not alter by exposure to the air, and are soluble in alcohol. *Subkinate of lead*, a white powder insoluble in water. *Kinate of copper* crystallises in green needles, or rhombic laminae; the surface becomes white by exposure to the air. *Perkinate of mercury*, a colourless salt which does not crystallise. *Kinate of silver* forms mammellated crystals, which readily blacken in the light.

When kinic acid or kinate of lime is distilled with sulphuric acid and peroxide of manganese, a new compound called *kinone*, or *kinöl*, is obtained. It occurs in crystals of a fine golden-yellow colour, which are soluble in water, having a pungent smell when in the state of vapour. When kinone is acted on by reducing agents, it takes up 2 and 4 equivalents of hydrogen, forming *green* and *white hydrokinone*. The first forms green crystals of exceeding beauty; the latter are white. Wöhler has obtained several compounds of kinone, of which the following tabular statement gives the names as far as they are yet known:—

Kinone	$C_{12}H_4O_4$
Green hydrokinone	$C_{12}H_8O_4, C_{12}H_6O_4$
White hydrokinone	$C_{12}H_8O_4$
Chlorohydrokinone	$C_{12}H_5ClO_4$
Chlorokinone	$C_{12}H_3ClO_4$
Kinonic acid	$C_{12}H_4O_8$
Trichlorokinone	$C_{12}HCl_3O_4$
Perechlorokinone, or chloranil	$C_{12}Cl_4O_4$

KINO, an astringent substance, the concrete juice of one or more plants. Most skilful pharmacologists are agreed in referring the East India kino, called also Amboyna kino, to the *Pterocarpus marsupium* (Roxb. 'Coromand. Plants,' ii., t. 116; 'Fl. Indica,' iii., p. 234), of which *Pterocarpus bilobus* is perhaps a mere variety, though a smaller tree. The first is a native of the Circar Mountains, and forests of the Malabar coast. No kino is imported at the present day from Africa, though the juice of *Pterocarpus crenaceus* is collected by the Senegambians for their own use in medicine and the arts. It is quite a misnomer to term the inspissated juice of the *Nauclea* (*Uncaria*) *gambier*, or *gambear*, African kino, as this shrub grows in the Indian Archipelago.

In Australia a sort of kino is procured from the *Eucalyptus resinifera* (White), which finds its way to the East Indies, where it is used as a cotton-dye, as indeed the other kinds are also, giving to cotton the yellowish-brown colour known as nankeen; the colour varies with the different sorts of kino used.

In the West Indies the juice of the *Coccoloba uvifera* is called American kino, or American extract of rhatany, or false rhatany extract. These different extracts differ in their chemical habitudes with re-agents, but they all agree in possessing a strong astringent power. Kino most commonly occurs in grains of a shining aspect and rich ruby-red colour; they are easily reduced to powder. It is nearly entirely soluble in water and in alcohol. Vauquelin analysed that sort which is termed African, and found it to consist of 75 per cent. of tannin, 24 of red mucilage, and 1 of woody fibre. [TANNIC ACID.]

Some of the kino of commerce is no doubt produced by *Butea frondosa*, which is common as a tree or shrub in every part of India. On comparing together specimens of the astringent gum of this plant, contained in Dr. Royle's collection, with some brought from North-western India by Mr. Beckett, and both these with some sent from Bombay as the kino of the *Butea frondosa*, they were all three found to be identically the same kind of gum; but Mr. Beckett's, from being the freshest specimen, was the most highly coloured. These were all moreover found to correspond, especially the specimens from Bombay, with some astringent gum found by Mr. Pereira in one of the old druggists' shops of London, under the name of *Gummi rubrum astringens*, which was the name by which kino was known. It was introduced into practice by Dr. Fothergill as *Gummi astringens Gambiense*. It is remarkable that the Sanskrit name of *Butea frondosa* is *kinsuka*. From its gum being labelled by a druggist as *Gummi rubrum astringens*, it is evident it must have been among the earliest substitutes for the African kind, of which so little has ever been imported into this country. Analysed by Mr. E. Solly, jun., the *Butea* kino was found to contain between 60 and 70 per cent. of tannin with gum. It is curious that Dr. Roxburgh remarks of the gum of the *Butea frondosa*, that it is so like that of his *Pterocarpus marsupium* that one description might suffice for both, with respect as well in appearance as to the action of chemical re-agents.

KINONE. [KINIC ACID.]

KINONIC ACID. [KINIC ACID.]

KINONIC GROUP (*Quinonic Group*), one of the groups of organic bodies belonging to the Benzoic series of Gerhard's system of classification. Several of the bodies belonging to this group are produced by the metamorphosis of phenylic alcohol, and of salicylic, and indigotic compounds. They are however usually prepared from the kinic acid contained in cinchona bark. The following are the principal bodies belonging to this group:—

Kinic acid	$C_{28}H_{22}O_{22}$
Kinone	$C_{12}H_4O_4$
Hydrokinone	$C_{12}H_6O_4$
Kinonic acid	$C_{12}H_4O_8$
Kinonamide	$C_{12}H_6N_2O_4$
Kinonamic acid	$C_{12}H_5NO_6$

KINOTANNIC ACID. [TANNIC ACIDS.]

KINOVATIC ACID ($C_{38}H_{30}O_{10}$) *Kinovic Acid*. A peculiar acid found in cinchona bark, and also produced by the action of acids and alkalis upon cinchonic acid. [CINCHONIC ACID.]

KINOVIC ACID. [KINOVATIC ACID.]

KIRK SESSIONS. [SESSIONS, KIRK.]

KIRSCHWASSER. A kind of spirit prepared in the Vorarlberg from cherries.

KITCHEN-GARDEN. Every one knows what is generally understood by this name, a kitchen-garden forming a sort of inseparable adjunct to every country-house, to the mansion of the rich as well as to the humble cottage. In laying out the grounds of a country residence provision should be made for the site of the kitchen-garden. Though it should not obtrude on the ornamental ground immediately adjoining the house, the design of the whole should be so formed as to leave the kitchen-garden in the most favourable situation with regard to aspect, soil, and water. The aspect should be open to the south, but sheltered on other sides, more especially from northerly and easterly winds, by rising ground or lofty trees at some distance. The surface should be nearly level, or in some cases, according to the pervious nature of the subsoil, it may be quite so; but, generally speaking, a gentle slope from north to south is best. The soil should consist of a rich loam, neither too light nor so adhesive as to be liable to bind strongly in dry weather. The depth of soil ought not to be less than two feet, and more is absolutely necessary for some kinds of vegetables. If the subsoil be very impervious it should be sub-trenched; and in doing this the undisturbed bottom of the whole area should form a regularly inclined plane towards a proper drain; or if more convenient the bottom may form several planes so inclined as to allow the water a descent to a drain running through the lowest points. In the formation of gardens this is frequently not sufficiently attended to; while care is taken that the surface of the soil should be fair to the eye, a comparatively unimportant circumstance. If the bottom be made as

above directed, the most important and difficult part of the groundwork is accomplished.

Water is very frequently obtained by means of pumps placed in convenient situations throughout the garden; but this is not the best mode of supply, nor should it be resorted to except where there is no alternative. Much injury is done to vegetation by watering with cold spring water, or indeed with any water that is much colder than the soil and atmosphere in which the plants are placed. Plants, when not watered at all in dry weather, if they are only kept alive, succeed better when rain does come than others that are watered, or rather chilled with water at a comparatively low temperature. The injurious effects of chilling plants by the application of very cold water is often visible in plants of the cabbage kind. After being transplanted from the seed-beds a quantity of cold water is immediately poured round their roots, the surrounding dry soils absorb a great portion of this supply, the remainder is soon exhaled by evaporation, and the process is again repeated. Sudden extremes of heat and cold, moisture and dryness, derange the functions of the spongioles and roots; obstructions supervene, and occasion an accumulation of matter in the thicker parts of the root, which is the principal cause of what is called *clubbing*, or the formation of protuberances in cabbage-roots, a disease which proves a check to their future development by incapacitating their roots for a due transmission of nourishment. Water for the kitchen-garden should therefore be derived from ponds or large reservoirs fully exposed to the sun, and even these should be supplied by open rather than underground channels; they should also be shallow, for the following reason—the deeper the water the longer will a considerable portion next the bottom retain the temperature of its greatest density, about 40° Fahr. When the general temperature of water is above this the warmest is next the surface; and therefore the flow of water for the garden should be from the surface of the pond or reservoir. This may easily be effected by means of a floating or float-controlled sluice. When a broad sheet of water cannot be obtained for the supply of a garden some advantage will be gained by providing large cisterns in which water raised by pumps may be exposed to the air for some time previous to its being used.

The quantity of ground which a kitchen-garden should contain must be regulated according to the number of individuals which it is required to supply. An acre is calculated to afford a tolerable supply for sixteen individuals, but much depends on the nature of the vegetables required. Potatoes, turnips, peas, and carrots are frequently obtained of better quality and at less expense from a field than from a garden. With respect to potatoes in particular, only early varieties are now generally cultivated in gardens. If the mansion be only fully occupied for a part of the season, the quantity of ground will require to be nearly as much as if the supply were required throughout the year. Thus for example, a considerable breadth may be found necessary for peas in spring, and the same may be occupied with broccoli in autumn; so that the ground which would be sufficient for a few months' demand may be made equally so for the whole season by a proper succession of crops. For similar reasons it will be found that where a steady supply is required, proportionably less ground will be requisite than when the demand alternately exceeds and falls short of the mean.

A moderate establishment will require two acres of kitchen-garden, and a large one five or six; and in either case it may be found necessary to have recourse to field culture for those productions to which that mode of rearing is more especially adapted.

The form of a kitchen-garden should be composed of straight lines. If rectangular, it will prove a saving of labour; for it is practically known that more time is required to trench a piece of ground of a triangular form, than if the same extent were in the shape of a square or parallelogram; and besides, labourers who may not happen to be accustomed to the method of working such figures as have inclined sides are liable to make the surface irregular. A range of forcing-houses is generally placed on the north side; and as the wall on that side is the most valuable for fruit-trees on account of its direct south aspect, it becomes desirable that it should be extended as much as possible on each or both ends of the range. The form of the kitchen-garden is consequently determined to be that of a 'parallelogram with the two long sides running due east and west. The melon-ground, containing also pits for culinary forcing, should form an adjoining compartment well sheltered and excluded from the view on account of the quantities of litter and other fermenting substances which it must necessarily contain.

It is found that grapes ripen better against a very high wall than they do when trained on a low one. The conclusion to be drawn from this fact must be, that a greater accumulation of heat will take place in front of a wall 12 feet high than where the height is less, and consequently the trees, whilst they have space for a greater extension, enjoy an increased degree of warmth. Therefore it will be desirable that the walls of a kitchen-garden should not be less than the height above mentioned, with the exception of the one on the south, which may be only 10 feet, because it will occasion less shade; and if the wall on the opposite or north side be made 14 feet high instead of 12 feet, greater utility and a better effect will result. Once erected, walls are too valuable to be left unoccupied, and a border should accordingly be formed outside, as well as inside, for the reception of fruit-trees to

be trained against them. This requires the enclosure of a slip, containing the wall-border, a walk, and a border between the latter and the outside fence. If this outside or *ring-fence* were formed of materials on which young trees could be trained, so as to fill any accidental vacancy that may occur on the principal walls, great advantages would accrue, for then the walls would always appear filled with trees in a bearing state. Such nursery trees should be carefully moved every second year, so that they may always be in a proper condition for their final destination.

The interior departments of the kitchen-garden are usually bounded by fruit-trees planted within two or three feet of the walks. Not only are bushes, such as gooseberries, currants, and raspberries, used for this purpose, but fruit-trees of various kinds. The latter are trained either as dwarfs by grafting apples on paradise stocks, and pears on quinces, and causing their branches to proceed from near the ground; or as espaliers. The latter were formerly more in use for training fruit-trees in kitchen-gardens than they are at the present time. Some object to their appearance, others to their expense compared with their utility. Their appearance is certainly not unsightly if they are not made too high; and although the old varieties of fruit-trees trained upon this plan were unprofitable, yet many of the new kinds will produce abundantly. They occupy very little space, and their shade, if not made higher than six feet, can be scarcely injurious, especially as it can be made to fall chiefly on the walk.

Very few of the subjects of kitchen-garden cultivation are indigestible; they are chiefly varieties of luxuriant habits, which are artificially maintained and augmented by the art of the cultivator. The principal means employed for rendering the soil of the kitchen-garden subservient to this purpose are,—the application of abundance of manure; trenching, digging, and otherwise stirring the soil; and a due rotation of crops. Manure supplied in abundance will generally produce luxuriance in vegetables, although sometimes a disagreeable rankness is communicated to the flavour. This is in a great measure corrected by trenching, which becomes occasionally highly necessary; and although expensive, it will always repay the cost, if judiciously performed, particularly if the soil be of a consolidating nature. Trenching exposes fresh soil, and gives rest to that which has been partially exhausted on the surface; it renders the soil pervious to water and air, and likewise for the roots of the plants; in wet weather the latter are free from stagnant moisture; and in drought they seldom suffer, because they have been able to penetrate the soil so far as to be beyond the reach of dryness. Moreover, if a thermometer is plunged in well loosened soil, after a few days of hot sun in March, it will be found to indicate a temperature many degrees above that in more compact earth, or where the soil has not been stirred for several years. The advantage of this communication of heat is obvious, especially when it is borne in mind that a number of kitchen-garden plants are natives of countries possessing a warmer soil and climate than those of Britain.

It is always advantageous to attend to a proper rotation of crops, especially where manure is not abundantly applied, nor trenching performed. One kind of plant should not immediately follow another of the same nature, or one closely allied. The selection of the plants or vegetables grown must depend wholly on the tastes and requisitions of the owners, but we may add that many of the commoner vegetables are most profitably raised by field cultivation.

(Lindley, *Theory and Practice of Horticulture*, 1855; Loudon, *Encyclopædia of Gardening*, 1850.)

KLAPROTHIUM. [CADMIUM.]

KNIGHT, KNIGHTHOOD. During the prevalence of the feudal system, when the military strength of the nation was measured by the number and efficiency of the knights whom the sovereign was able to summon to the field, a regular supply of persons qualified to perform in an effectual manner the services annexed to their tenures was a matter in which the public as well as the crown were deeply interested; and the common law adopted that part of the feudal system which enabled the king, by process of distress [DISTRESS], to compel those who held knight's fees [KNIGHT'S FEES] to take upon themselves the order of knighthood, or, in other words, to prove, by their reception into that order, that they had received the training and possessed the arms and accoutrements, and were, as to other requisites, qualified to take the field as knights. The statute, or rather the grant of Edward II., enrolled in parliament, called "*Statutum de Militibus*," appears to have been made, partly as an indulgence upon the commencement of a new reign, and partly for the purpose of removing some doubts which existed as to the persons liable to be called upon to receive knighthood. The king thereby, in the first place, granted a respite until the following Christmas to all those who ought to have become, but were not, knights, and were then distrained *ad arma militaria suscipienda*. Further, it directed that if any complained in Chancery that he was distrained and had not land to the value of 40*l.* in fee, or for term of his life, and was ready to verify that by the country (that is, by the decision of a jury), then some discreet and lawful knights of the county should be written to, in order to make inquiry of the matter; and if they found it to be so, he was to have redress, and the distress was to cease. Again, where a person was impleaded for the whole of his land, or for so much of it that the remainder was not of the value of 40*l.*, and he could verify the fact,

then also the distress was to cease till that plea was determined. Again, where a person was bound in certain debts attermated in the exchequer at a certain sum to be received thereof annually (that is, respited, subject to payment by instalments), and the remainder of his land was not worth 40*l.* per annum, the distress was to cease till the debt was paid. No one was to be distrained *ad arma militaria suscipienda* till the age of twenty-one, or on account of land which he held in manors of the ancient demesne of the crown as a sokeman, inasmuch as those lands were liable to pay a tallage when the king's lands were tallaged. With respect to those who held land in socage of other manors, and who performed no *servitium forinsecum*, or service due upon the tenure, though not expressed in the grant, the rolls of chancery in the times of the king's predecessors were to be searched, and it was to be ordered according to the former custom; the same of clerks in holy orders holding any lay fee, who would, if laymen, have been liable to become knights. No one was to be distrained in respect of property of burgage tenure. Persons under obligations to become knights, who had held their land only a short time, were extremely old, or had an infirmity in their limbs, or had some incurable disease, or the impediment of children, or law-suits, or other necessary excuses, were to appear and make fine before two commissioners named in the act, who were to take discretionary fines from such disabled persons by way of composition. Under this regulation, those who were distrained upon as holding land of the value of 40*l.* per annum either received knighthood or made fine to the king. The alteration in the nominal value of money occasioned by the increased quantity of the precious metals, and still more by successive fraudulent degradations of the standard, gradually widened the circle within which estates were subjected to this burden; and in the 16th and 17th centuries lands which in the reign of Edward II. were not perhaps worth 4*l.* per annum, had risen in nominal value to 40*l.*, and were often held by persons belonging to a totally different class from those who were designated by 1 Edward II., stat. 1, as persons having 40 *libratas terræ*.

That power of compelling those who refused to take upon themselves the order of knighthood, or rather of distraining them till they received knighthood, or compounded with the king by way of fine, which originally was a means of enforcing the performance of a duty to the crown and to the public, by persons holding a certain position and having a certain stake in the country, was perverted into a process for extorting money from those who would have been exempt at common law, which regulated the amount of a knight's fee by the sufficiency of the land to support a knight, and not by its fluctuating nominal value in a debased currency. This oppressive, if not dishonest proceeding, which was occasionally resorted to in the reigns of Edward VI. and Elizabeth, was reduced into a system by the rash advisers of Charles I., and was adopted by that unfortunate prince as one of the modes by which money might be raised without resorting to a parliament for assistance. The undisguised manner in which this ancient prerogative was thus abused, led to its total abolition. By 16 and 17 Car. I., c. 20, it is enacted, that none shall be compelled, by writ or otherwise, to take upon him the order of knighthood, and that all proceedings concerning the same shall be void.

Persons have been required to take upon themselves the order of knighthood as a qualification for the performance of honourable services at coronations, in respect of the lands which they held by grand serjeanty.

Knighthood in England is now conferred by the king (or queen when the throne is filled by a female) by simple verbal declaration attended with a slight form, without any patent or other written instrument. Sometimes, but rarely, knighthood is conferred on persons who do not come into the presence of royalty. This is occasionally done to governors of colonies, and other persons in prominent stations abroad. The lord-lieutenant of Ireland has a delegated authority of conferring this honour, which is very sparingly exercised.

Knighthood gives to the party precedence over esquires and other untitled gentlemen. "Sir" is prefixed to the baptismal name of knights and baronets, and their wives have the legal designation of "Dame" which is ordinarily converted into "Lady." Knighthood is, however, not hereditary, but merely personal.

A rank correspondent to our rank of knighthood has been found in all Christian countries. Some regard it as a kind of continuation of the equestrian order among the Romans. But it is safer to regard it as originating in Christian times; and the 11th and 12th centuries have been named as the period to which the order of knighthood as now existing may be traced. In such an inquiry there are two difficulties: first, to state with sufficient precision what is the thing to be proved; and, secondly, to obtain evidence of the commencement of an institution which probably grew, almost insensibly, out of a state of society common to the whole of civilised Europe.

It was a military institution, but there appears to have been something of a religious character belonging to it, and the order of knight hood, like the orders of the clergy, could be conferred only by persons who were themselves members of the order.

In early times some knights undertook the protection of pilgrims; others were vowed to the defence or recovery of the Holy Sepulchre. Some, knights-errant, roved about "seeking adventures,"—a phrase no confined to books of romance, of which there are many on this subject but found in serious and authentic documents.

But besides those who are simply knights, there are knights who are members of particular orders or classes.

These orders are found in most of the kingdoms of modern Europe, and have had generally for their founder a sovereign prince. Such are the order of the Golden Fleece, instituted by Philip, duke of Burgundy; the order of the Holy Ghost, instituted by Henry the Third of France; the order of St. Michael, instituted by Louis the Eleventh of France. Of the foreign orders, which are very numerous, the most recent account will be found in a work entitled 'A Concise Account of the Several Orders of Knighthood, and other marks of honourable distinction,' by Nicholas Carlisle, 8vo, 1839. Foreign orders cannot be worn by British subjects without the special consent of the sovereign. Each of these orders has its peculiar badge, ribbons, and other decorations of the person. The British orders are the Garter and the Bath, (which are treated of under the heads of GARTER, KNIGHTS OF THE, and BATH, KNIGHTS OF THE), the Thistle, and St. Patrick.

The order of the Thistle was instituted in 1540, by James V. of Scotland; but it fell into decay, till in the reign of Queen Anne, 1703, it was revived. The number of knights was limited to thirteen, but in 1827 the number was increased to sixteen, all of whom are nobility of Scotland.

The order of St. Patrick was instituted in 1783. The knights were fifteen, increased in 1833 to twenty-two, who are peers of Ireland.

There are also knights of the Guelphic order, and knights of the Ionian order of Saint Michael and Saint George. Carlisle mentions an African order of the Palm and Alligator, instituted by the kings of Soudan.

KNIGHT OF THE SHIRE is the designation given to the representatives in parliament of English counties, as distinguished from such cities and towns as are counties of themselves (which are seldom, if ever, called shires), and the representatives of which, as well as the members for other cities and towns, are denominated citizens or burgesses. Though the knights of the shire always sat with the citizens and burgesses as jointly representing the third estate of the realm, as well during the time that the three estates, viz. the spirituality, the lords temporal, and the commons, sat together, as since, we find that grants were occasionally made by the knights to be levied on the counties, whilst separate grants were made by the citizens and burgesses to be levied upon the cities and boroughs. ('Rot. Parl.') The wages payable to knights of the shire for their attendance in parliament, including a reasonable time for their going up and coming down, were four shillings a day, being double what was received by citizens and burgesses. At the close of every session the king, in dismissing them to their homes, informed them that they might sue out writs for their wages, upon which each knight separately obtained a writ out of Chancery directed to the sheriff mentioning the number of days and the sum to be paid, and commanding the sheriff to levy the amount. Upon this the sheriff, in a public county court, divided the burden amongst the different hundreds and townships, and issued process to levy the amount, which, to the extent of the money levied, he paid over to the knight. The lands of the clergy, as well regular as secular, were exempted from contributing towards these expenses, because the clergy formed a distinct estate, and were represented in parliament by their prelates and the procuratores cleri, although the latter were, as Lord Coke expresses it, voiceless assistants only. All lay fees within the county were liable to contribute, except lands belonging to the lords and their men. The lords insisted that this exemption extended to every freeholder who held land within their baronies, seigniories, or manors, alleging that they served in parliament at their own expense for themselves and their tenants. And such was undoubtedly the practice; as by the Parliament Roll it appears that the commons frequently petitioned that the exemption should be confined to such lands as the lords kept in their own hands and occupied by their farmers or by their bond-tenants, or villeins. These requests however were met either by a simple refusal or by a statement by the king that he did not mean to lessen the liberties of the lords. If however a lord purchased land which had previously been contributory to the knight's wages, the liability continued. Freehold lands, held either by knight's service or in common socage, were liable to this burden, but customary tenures in ancient demesne and tenures in burgage were exempt. In the county of Kent no socage land was contributable, the whole burden being thrown upon those who held knight's fees, an anomaly against which the commons preferred many ineffectual petitions. Knights of the shire, and also their choosers, were formerly required to be persons either resident or having a household in the county. This regulation, though confirmed by several statutes, had fallen into neglect long before it was formally abrogated in both its branches by 14 George III., c. 58. ('Rot. Parl.')

As to the qualifications of electors, and the disqualifications from sitting as knights of the shire, see PARLIAMENT.

KNIGHT'S FEE was land of sufficient extent and value to support the dignity of a knight, granted by the king, or some inferior lord, upon the condition that the grantee and his heirs should either perform the service of a knight to the grantor and his heirs, or find some other person to do such service. The quantity of land capable of supporting a knight naturally varied according to its quality and situation; and even the amount of income sufficient to meet the charges of a knight would fluctuate according to time and place. It is not therefore surprising that we find a knight's fee sometimes described as consisting

of 800 acres, sometimes of 680; sometimes estimated at 15*l.* sometimes at 20*l.*, and in later times at 40*l.* per annum. If the owner of a knight's fee deprived himself of the possession of part of his land by subinfeudation he remained liable to the feudal burden attached to the tenure of the whole.

KNIGHT'S SERVICE, TENURE BY, otherwise called tenure in chivalry, or per service de chivaler, per servitium militare, was, from the times immediately succeeding the Norman Conquest in the 11th century to the period of the civil war in the 17th, considered the first and the most important, as it was also the most general, mode of holding land in England. The land thus held was said to consist of so many knight's fees, feoda militis, that is, so many portions of land capable of supporting the dignity of a knight. [KNIGHT'S FEE.] He who held an entire knight's fee was bound by his tenure, when called upon so to do, to follow his lord to the wars (under certain restrictions as to the place at which the service was to be performed), and to remain with him forty days in every year, or to send some other knight duly qualified to perform the services. From the owner of half a knight's fee twenty days' attendance only could be required; and the obligation attaching to the quarter of a knight's fee was satisfied by the performance of ten days' service. On the other hand, a person holding several knight's fees, whether forming one or several estates, was bound to furnish a knight in respect of each.

Besides this permanent liability to military service, the tenant was subject to other occasional burdens. The principal of these are the following incidental services:—First, *Aids*, or payments which the vassal holding by knight's service was bound to make for ransoming his lord's person if taken prisoner; for making the lord's eldest son a knight; and for marrying, that is, providing a marriage portion for the lord's eldest daughter. Secondly, *Reliefs*, being a payment made by the heir in the nature of a composition for leave to enter upon land descending to him after he had attained his full age. Thirdly, *Primer Seisin*, or the right of the crown, where the lands were held of the king, to a year's profit of land descending to an heir who was of full age at the time of the death of his ancestor. Fourthly, *Wardship*, or the right to the custody of the body and lands of an heir to whom the land had descended during his minority, the king or other lord in such case taking the profits of the land during the minority to his own use, or selling the wardship to a stranger if he thought proper. Fifthly, *Marriage*, or a right in the lord, where the land descended to an heir within age, to tender to him or her a wife or a husband; and if the heir refused a match without disparagement, that is, without disparity of rank, crime, or bodily infirmity, the lord became entitled to hold the land as a security for payment by the heir of the amount for which the lord had sold or which he might have obtained for the marriage. Sixthly, *Fines upon Alienation*. To these Blackstone adds a seventh, *Escheat*, or the returning of the land to the lord upon the felony or forfeiture of the tenant, or his dying without heirs. [ESCHEAT.] But escheat is not peculiar to tenure by knight's service.

This system, which Blackstone justly characterises as a complicated and extensive slavery, fell to the ground during the existence of the Commonwealth; and the abolition of this species of tenure was confirmed upon the Restoration, as it would have been absurd and dangerous to attempt a renewal of such oppressive burdens. Accordingly, the 12th Car. II., c. 24, takes away tenure by knight's service, whether the lands are held of the crown or of a subject, together with all its oppressive fruits and peculiar consequences, and converts every such tenure into free and common socage. [SOCAGE.] Nothing can be more comprehensive than the terms of this act; besides generally abolishing tenure by knight's service, and its consequences, it descends into particulars, with a redundancy of words, which appear to indicate an extreme anxiety to extirpate completely all the evils which the legislature had under contemplation. The statute, after taking away the court of wards and liveries, enumerates wardships, liveries, primer seisins or ousterlemains, values and forfeitures of marriages, and fines, seisures, and pardons for alienation, and sweeps away the whole. But rents certain, heriots [HERIOT], suit of court and other services incident to common socage, and fealty [DISTRESS], and also fines for alienation due by the customs of particular manors, are preserved. Reliefs for lands, of which the tenure is converted into common socage, are saved in cases where a quit-rent is also payable.

KOENLITE. A fossil hydrocarbon resembling paraffin.

KORAN. [MOHAMMED, in BIOG. DIV.]

KOUMISS. *Kumiss*. A kind of spirit distilled by the Arabs from mare's milk which has undergone fermentation in leathern bags. The alcohol it contains is derived from sugar of milk.

KOUSSO, or COSSO. Under these names are comprehended the flowers and flower-stalks of a tree, native of Abyssinia, long celebrated among the natives for its anthelmintic properties. The earliest notice of it among European writers was by Leutholf, in 1681 ('Hist. Æthiopica,' lib. I., c. ix, sect. 31); but the first representation of it occurs in Bruce's 'Travels' (vol. v., p. 73, of London edition, 1790). By him it was proposed to call the tree *Banksia Abyssinica*, a generic name untenable as having been previously appropriated to a New Holland genus. *Hagenia*, applied to it by Lamarck, is for the same reason untenable. The universally admitted name is *Brayera anthelmintica*, Kunth (D. C. 'Prod.' ii., p. 588), [NAT. HIST. DIV.]; also, Richard,

'Tentamen Floræ Abyssinicae,' pl. 48. Dr. Beke says that the tree in the Amharic language is called *kosso*, and in that of Tigre *hhäbbe*; and these same names are respectively applied to the tape-worm, against which this drug is esteemed a remedy. It flourishes best on the table-land in the north-eastern part of Abyssinia, at the height of six or seven thousand feet above the level of the sea. It is a rosaceous plant, though by Theodor d'Abbadie ascribed to the *Malvaceæ*. The flowers and flower-stalks are collected before the seeds are quite ripe, whilst still a number of florets remain unchanged. They are suspended in the sun to dry, and if not required for immediate use, are deposited in a jar. The dried portions are sent first to Egypt, thence to Constantinople, and Europe; perhaps some come to Aden.

The chemical analysis yields a fatty oil, wax, bitter acrid resin, tasteless resin, two kinds of tannin, ashes, gum-sugar (Wittstein). Martin gives also a crystalline substance termed *kwoseine*; there is also a little volatile oil. Owing to the high price adulteration is much practised, chiefly with pomegranate bark. To avoid this the *kouso* should be purchased in the entire, not powdered, state. About half an ounce is the dose for an adult. This is to be infused in half a pint of tepid water for a quarter of an hour, a little lemon-juice may be added, and about a third swallowed; then after an hour another third, finally the remainder, with lemon-juice. This seems to check the disposition to vomiting caused by the nauseous taste and odour. At the end of four hours, a dose of castor-oil or infusion of senna may be given. By the action of this last tape-worms, either entire or in part, mostly dead, are brought away. The chief recommendation of *kouso* over other anthelmintics seems to be that under its influence the head as well as the joints of the parasite are brought away. Without this be effected any amendment can only be temporary. The fullest account of *kouso*, in English, is by Dr. Pereira, in 'Journal of Pharm. Society,' vol. x. p. 15, now incorporated in Pereira's 'Mat. Med.' [ANTHELMINTICS.]

KRAMERIA TRIANDRA, or **RHATANY**, is a small low-lying undershrub, growing on the dry projecting parts of the mountains of Peru, near Huanaco, &c. The native name is *Rhatanha*. The root, which is the officinal part, is from four to eight inches long, and from the size of a writing quill to two inches thick, with knotty but not strong ramifications, and is very variable in shape. The bark is thin, uneven, and easily separates from the woody part. The bark bears a larger proportion to the woody part in the young than in the old ramifications, and contains more astringent matter. The young ones are to be preferred. The root is heavy, and devoid of odour; but the taste, especially of the bark, is strongly astringent and bitter, yet not disagreeable. Iodine turns it black. According to the analysis of Gmelin, it contains much tannin, with saccharine and mucilaginous matter, woody fibre, and salts. According to Peschier, it contains *krameria* acid. This root, from which, in Peru, an extract is formed, is a mild, easily assimilated, astringent medicine, possessed of great power in passive bloody or mucous discharges; and also in weakness of the digestive organs, muscular debility, and even in intermittent and putrid fevers. The powder forms, along with charcoal, an excellent tooth-powder; and an infusion is used as a gargle and wash. The chief use of the extract imported from South America, is said to be the adulteration of port wine.

KRAMERIC ACID. A peculiar acid of unknown composition, said to exist in the extract of *Rhatany* (*Krameria triandria*). It is a non-volatile, difficultly crystallisable solid.

KREASOTE. [CREOSOTE.]

KREATINE. Synonymous with creatine. [CREATINE.]

KREATININE. [CREATININE.]

KRESYLIC ACID. Synonymous with *hydrate of cresyl*. [CRESYL.]

KRISHNA. [VISHNU.]

KRONOS, one of the most ancient of the Greek gods, the youngest of the Titans, and father of Zeus. Kronos was the son of Uranus and Gæa. Uranus, who was ruler of the world, out of fear or hatred of his children, especially of the Cyclopes, cast them into Tartarus and kept them imprisoned there. In revenge Gæa incited the Titans to rebel against their father, and gave to Kronos a sickle (*ἄρρη*) of adamant, with which he deprived his father of virility. Uranus being deposed, Kronos was raised to his throne, and the Cyclopes liberated; but they were again cast by Kronos into Tartarus. Kronos now married his sister Rhea, and had by her Hestia, Demeter, Hera, Hades, Poseidon, and Zeus; but it having been foretold him by Uranus that he should be deposed by one of his children, he swallowed all of them but Zeus as soon as they were born. On the birth of Zeus, Rhea gave Kronos a stone wrapped in a cloth, which he swallowed, believing it to be his newly born child. Rhea concealed her son in a cave in Crete, where he passed the first years of his life. When Zeus grew up, Kronos, in order to secure his throne, called the Titans to his aid; but Zeus, by the counsel of Thetis, administered a potion to Kronos, which caused him to bring up the children he had swallowed. Zeus, with his brothers and sisters, now attacked the Titans, who, after a contest which lasted

ten years, and which was known to the Greeks as the Titanomachia, were eventually conquered, and Kronos was dethroned.

In Greek art Kronos is often represented with a veil covering the back of his head; and almost always with the harpe, or sickle, in his hand. Sometimes he is figured enthroned, with Rhea offering him the stone; sometimes he is naked, at others wrapped in voluminous drapery.

Greek and Roman writers regarded the Greek Kronos and the Roman Saturnus as the same deity. By recent writers their identity has been doubted. Their identity has been maintained with strong arguments by Buttmann, 'Mythologus,' ii. 28, &c.; but as strenuously opposed by Hartung, 'Die Relig. der Röm.' ii. 123, &c., who considers the two divinities as quite distinct, and Saturnus as an ancient national divinity of the Italians. Certain it is that there are few if any points of resemblance between their attributes: the chief coincidence is that each was regarded as the most ancient deity of his country. Both the deities are figured in ancient works of art with a sickle in their hand; but the sickle of Kronos had reference to the harpe given him by his mother Gæa, while that of Saturnus was typical of his protection of husbandry.

Saturnus was one of the principal divinities of the ancient Italians. He was considered to be the protector of agriculture, and of all civilisation arising from it. His name probably contains the same element as the verb *sero* (*sa*), whence he was considered as the protecting divinity of all that was sown and planted, and as the giver of plenty. The Italian legends represented him as having come from abroad to the shores of Italy, in the reign of Janus, by whom he was hospitably received. Notwithstanding this, Saturnus was always considered as the first king of the Aborigines, probably because agriculture and civilisation in Italy dated from his reign. (Virg., 'Aen.,' viii. 319; Aurel. Vict., 'De Orig. Gent. Rom.,' c. 1, &c.) He was said to have established a settlement on the Capitoline Hill, which from this circumstance was called the Saturnian Hill, and the settlement itself Saturnia. He now began to teach the Italians the art of cultivating the fields, and led them from their savage state to the peaceful occupations of civilised life, so that the whole land of Italy was called, after him, Saturnia, or the land of fruit. In agriculture he is said to have taught his subjects the use of manure (*stercus*), from which he derived the surnames of *Stercutus*, *Stercilinus*, and *Stercenius*. (Macrobius, 'Sat.,' i. 7.) His rule was so just and mild, that the age in which he reigned was afterwards described as the golden age of Italy. His wife, called Ops, was in aftertimes worshipped as the goddess of plenty. After the death of Saturnus, or rather after his disappearance from the world, he was raised to the rank of a god, an altar was erected to him on the spot which was afterwards called the Forum, and a temple near the foot of the Capitoline. Concerning his worship at Rome, see SATURNALIA.

KUMISS. [KOUMISS.]

KUTEERA, or **KATI'RA**, a kind of gum, considered in India by the native practitioners of medicine to be a good substitute for Tragacanth. Indeed, they consider it to be the true Tragacanth, which is described by Avicenna under the name *kuseera* in the original Arabic, while the plant which yields it is named *Ketad*, and its gum *Dragacanthum*. The Kuteera gum a good deal resembles Tragacanth in appearance, but does not in other respects correspond with that gum, according to the experiments which have been made on it in Europe. It has been described by Martius under the name *Kuteera* ('Pharmakognosie,' p. 338), which Guibourt says is the same as his *Gomme de Bassora*; it is intermediate between tragacanth and bassorin—when pure, it is almost entirely bassorin. Like the latter, it swells very much in water, and has a faint vinegar-like odour. Dr. Roxburgh states that *Sterculia urens* "yields a gum not unlike Tragacanth, and has been sent to London as such; but the artists, who use that gum, did not find it answer." He however mentions that the water in which he kept the green branches for examination became thick, like a clear glutinous jelly, while the bark was exceedingly astringent. ('Fl. Ind.,' p. 111.) Dr. Royle, on the contrary, states that the gum called *Kuteera*, and used as a substitute for Tragacanth in north-western India, is yielded by *Cochlospermum Gossypium*, and he possesses some of the same kind of gum collected by Mr. Malcolmson in Central India, accompanied with specimens of the tree which yielded it. This is identically the above-named species, which is so highly ornamental on the lower mountains of India, with its large and rich-coloured yellow flowers. Martius considers that it may be the produce of *Acacia leucophloea*, Willd. or of a *Simaruba*, the latter conjecture a very improbable source. This gum is used in dyeing. Mr. Simmonds says that Kuteera and Kutira are two distinct gums; the former from *Sterculia urens*, the latter from *Cochlospermum Gossypium*. (Simmonds' 'Dictionary of Trade Products.')

KYANOL. [ANILINE.]

KYNURENIC ACID. [CYNURENIC ACID. Improperly inserted as CYANURENIC ACID.]

L

L is a liquid formed at that part of the palate which is near the teeth.

It is therefore allied at once to the adjoining liquids *r* and *n*, and to the palato-dental consonants. The various forms which the letter has assumed may be seen in ALPHABET. The interchanges to which it is liable are as follows:—

1. *L* is interchangeable with *r*. Hence from the Greek or rather Latin *apostolo*, *epistola*, the French have derived *apostre*, *apôtre*; *epistre*, *éptre*. Again, in Latin, while from *rivo*, a stream, *rivali*, living near the same stream, and from *aevo*, age, *aequali*, of the same age, are derived; yet *populo* and *familia* lead to the adjectives *populari*, *familiari*, belonging to the same people, or the same family. These last words it will be observed already possessed an *l*. In the same way the well-known town on the African coast has been called at different times *Algiers* and *Argel*. The Spanish *coronel* corresponds to our *colonel*. Caralis, in Sardinia, is now Cagliari. Salamanca was called in ancient times Salmantica and Hermandica.

2. *L* with *n*, as *Barcino* (onis), *Barcelona*; *Ruscino*, *Roussillon*; *Bonia*, *Bologna* or *Boulogne*, *Nebrissa*, *Lebrissa*; *πνευμων* from *πνεω* or *πλευμων*, Lat. *pulmo*; *benus* and *bellus* in Latin, *βεντιστος* and *βελτιστος* in Greek: *λιτρον*, *nitrum*; *anima* in Lat., Ital. *alma*.

3. *L* with *d*, as *St. Aegidius*, *St. Giles*; *gridiron*, meaning *grill-iron*; and the English title *admiral* is derived from the Spanish *almirante*. But see D, No. 4. *L* is also interchangeable with *t*. (See T.)

4. *Ll* in the middle of words with *li*. Examples of this are abundant in the French pronunciation of the *l mouillé*. Hence from the French *billards* is derived without much alteration of sound the English *billiards*. It is somewhat strange that the English name *Villiers* and the French *Villars*, which are no doubt of the same origin, should be pronounced so perversely that the first writes an *i* and omits to sound it, and the second gives an *i* to the ear and none to the sight. This change prevails between the Greek and Latin languages, as *φυλλο* and *folio*, a leaf; *αλλο* and *alio*, other; *αλλ* and *sali*, leap. Even in the Greek itself *μαλλον* must be a corruption, as analogy would require *μαλα*, *μαλιον*, *μαλιστα*. It is probable indeed that the Greeks gave to the double *l* in this word the same sound as the French now do. On any other principle it would be impossible to defend the circumflex accent, which is only placed on syllables terminating in a vowel. It would perhaps not be wrong to write *σκυλλο* rather than *σκυλο*, corresponding to the Latin *spolio*, a skin or covering. With these forms may be compared *Mallorca*, pronounced *Mayorca*, the Spanish name for *Majorca*. Lastly, the Portuguese write *lh* with the same sound.

5. *L* disappearing. Not very dissimilar is the Italian interchange of *pl*, *cl*, *fl*, with *pi*, *chi*, *fi*; as from *pleno*, full, *pieno*; *piano*, flat or low, *piano*; *Placentia*, *Piacenza*; *clavi*, a key, *chiave*; *claro*, bright, *chiaro*; *clamare*, to call, *chiamare*; and *flor*, a flower, *fiore*; *fluctu*, a wave, *fio*; *Florentia*, once *Fiorenza*, now *Firenze*, the existing name of Florence.

This loss of an *l* after a consonant appears in other languages. The German *fliegen*, to fly, has for its chief element *flug*, corresponding to the Latin *fug*. In the same language *flispern* and *fispern* both mean to whisper; *fittich* and *fittich* both mean a wing; *blinzen* corresponds to the English words *blink* and *wink*. The word *dreifach*, threefold, is derived from *drei* and *flach*. Again the Greek *υπνο* and the Latin *somno*, *sopor*, have *sop* for the radical syllable. In the Gothic *in-sueppan*, the same root has the form *suep*, but in the German *schlaf*, and in English *sleep*. Lastly, the Latin *claud*, shut, and *clavi*, key (words of the same origin, as is proved by the various forms of *suavi*, sweet), appear in German in the form *schluss*, and in English as *shut* and *key*.

6. *L* with *u*, particularly after an *a*. *Alfidena*, a town, or *Aufidena*; *ελεημοσυνη*, pity (used by ecclesiastical writers to signify charitable gifts), Ital. *limosina*, Fr. *aumône*, Eng. *alms*; Lat. *altari*, an altar, Fr. *autel*; Lat. *aliqui-uno*, Ital. *alcuno*, Fr. *aucun*; Lat. *ulna*, Fr. *aune*. The French also contract the pronoun and article *à le*, *à les*, to *au* and *aux*.

7. Many words beginning with an *l* once had other consonants before the *l*, as in Latin, *loco*, a place, *liti*, a suit, *lato*, broad, were once preceded by *st*—thus, *stloco*, *stliti*, *stlato*. This explains how *lato* in Latin is the participle of *toll*. It must once have been *tlato*, corresponding to the Greek forms of the same root, namely, *τλη-τος*, *τλη-μων*, as well as *τολ-μη*. Again the English *liquorice* is a corruption from the word *glyco-rhiza*, sweet-root. To this head perhaps belongs the Welsh sound of words beginning with *ll*, as for example all the places beginning with *Llan*, which is pronounced by some as *thlan*, by others as *flan*. Perhaps *lana* and *flannel* are kindred words.

8. *L* is very apt to appear in a root, sometimes before a vowel, sometimes after one, as in the Greek words *καλε* or *κλη*, *βαλ* or *βλη*, &c. Where this slipping occurs after a sound like *k*, the *l* is apt to be converted into an *r*. Thus the Greek *σκαλεν*, poke, is in Latin *scrutari* (compare the phrase *scrutari ignem*, to poke the fire). So *καλυπτω* and

κρυπτω are of the same origin; *σκελος* and the Latin *crus*, *σκολοψ* and *crux*; *celeber* and *creber*.

LA, in music, the name given in England, Italy, and France, to the sixth of the syllables used in solmisation [SOLMISATION], and by the two latter countries to the note called *A* by the Germans and English.

LABORATORY, the room in which chemical operations are performed. The requisites for the proper arrangement of, and the necessary instruments for, a laboratory may be seen at length in Professor Faraday's 'Chemical Manipulation,' or in Williams's 'Handbook of Chemical Manipulation.'

LABOUR. [WAGES.]

LAC, a resinous substance, which in the East Indies flows from certain trees in the state of a milky fluid, on account of the puncture made by a small insect, the *Coccus ficus*, in their branches, in order to deposit its ova. The trees are principally the *Ficus Indica*, *Ficus religiosa*, and *Rhamnus jujuba*.

There are three kinds of lac known in commerce, and they are distinguished by the names of *stick-lac*, *seed-lac*, and *shell-lac*. *Stick-lac* is the substance in its natural state; it is of a reddish colour, and encrusts small twigs; when broken off and boiled in water, it loses its red colour, and is then termed *seed-lac*; and when melted and reduced to the state of thin plates, it is called *shell-lac*, which has a yellowish-brown colour. Mr. Hatchett appears to have been the first chemist who minutely examined these substances, but Dr. John, who has more recently examined *stick-lac*, gives as its composition—

Resin, insoluble in ether	66.66
Laccin	16.66
Colouring matter	3.75
Extractive	2.50
Cochineal coloured coverings of insects	2.08
Waxy tallow	1.66
Laccic acid	0.62
Yellow extract	0.41
Salts of potash, lime, iron, and earthy matter	1.66
Loss	4.

100.

Notwithstanding the seeming accuracy of the details of the above-mentioned analysis, it would appear that further experiments are still required to determine the nature of lac; for Unverdorben has, since this analysis was published, stated the results of his examination; 1st, laccin; 2nd, red colouring matter; 3rd, resin soluble in alcohol, but not in ether; 4th, resinous looking matter, slightly soluble in cold alcohol; 5th, crystallisable resin; 6th, uncrystallisable resin, soluble in alcohol and ether, but not in naphtha; 7th, wax; 8th, fat of coccus, not saponifiable, and some oleic and margaric acids.

Shell-lac is largely employed in the manufacture of sealing-wax; it answers this purpose better than any other resinous matter, because it melts without charring, and consequently without giving much smoke, and also because it is hard and less brittle than other resins. Shell-lac is also used in varnishes; and is so good an insulator of electricity that a needle made of it is said to remain some days excited.

Laccin.—The properties of the substance to which this name has been given, and which remained after the lac had been repeatedly digested in alcohol and water, are, that it is hard and brittle, of a yellow colour, and slightly transparent. It is insoluble in water, but softens in it when hot; and it also swells and softens, but without dissolving, in alcohol either cold or hot; nor do ether or oils take it up. It is dissolved by concentrated sulphuric acid. Concentrated nitric acid, when heated, dissolves it slowly. Solution of potash dissolves it readily.

Laccic acid separates from solution in water, by spontaneous evaporation, in crystalline grains. It attracts moisture from the air, does not precipitate either the salts of lime or baryta, but throws down those of mercury and lead; the persalts of iron are precipitated white by it. With the alkalis and with lime it forms salts which are soluble in alcohol and in water, and are deliquescent.

The colouring matter of *stick-lac* is said to be similar to that of cochineal. It is used for the same purposes, and yields a scarlet but little inferior to it.

Lac Dye and **Lac Lake**, two preparations of lac which are manufactured in the East Indies, and used to a very considerable extent in scarlet dyeing: they appear to be prepared by dissolving *stick-lac* in an alkali, as potash or soda, and then adding a solution of alum; by this there is precipitated a mixture of the alumina of the alum and the resinous and colouring matter of the *stick-lac*. The lac dye is much the more valuable of the two.

The principal uses to which lac in its various forms is applied are for the making of sealing-wax, for varnishes, for japanning, and for

scarlet dyeing. The trade in lac has of late years become of some importance.

LACE MANUFACTURE. All the varieties of lace are easily grouped into two classes, according as they are made by hand or by machine.

Hand or Pillow Lace. This fabric differs essentially in form and appearance from the products of an ordinary loom. Until about three centuries ago, lace was made by the needle on a piece of fine woven material, the threads of which were drawn aside to form holes or meshes, held in position by a few stitches. In 1561 Barbara Uttmann, of Annaberg, devised a mode of twisting threads round pins, so as to form a knotted or netted fabric; this was the real origin of pillow lace, the making of which gradually extended to various European countries.

The implements used by hand-lace-makers are few in number, and inartificial in character. They consist of a pillow or cushion, a series of bobbins or small cylindrical pieces of wood round which the thread or silk employed is wound, and pins which are stuck into the cushion and around which the threads are twisted. The pattern of the lace is determined by the disposition of the pins; and this is regulated by holes pierced in a piece of parchment which is laid upon the cushion. It is not possible to give in writing an intelligible description of the processes of lace-making by means of these implements; but it will be understood that the effect is produced by the twisting together of the threads upon the bobbins, and their being woven among and around the pins. The pattern depends partly upon the order of arrangement preserved in these twistings and weavings, and partly upon the introduction of a thicker thread, called *gimp*, which is used for the formation of figures, flowers, and other ornaments.

The finest pillow-lace is made on the continent. It is known in most cases by the names of the towns in which the fabrication is chiefly carried on. The most valuable is *Brussels*, of which there are two kinds, *Brussels-ground* and *Wire-ground*. *Brussels-ground* has a hexagon mesh, formed by plaiting and twisting four threads of flax to a perpendicular thread; whereas *Wire-ground* consists of silk, the meshes partly straight and partly arched, and the pattern, worked separately, being set on by a needle. *Mechlin lace* has a hexagon mesh formed of three flax threads twisted and plaited to a perpendicular thread; the pattern being worked in the net. *Valenciennes lace* has an irregular hexagon mesh, formed of two threads partly twisted and plaited at the top of the mesh; the pattern is worked on the net. *Lisle lace* has a diamond-shaped mesh, formed of two threads plaited to a perpendicular. *Alençon blond* has a hexagon mesh of two threads; it is one of the poorest of pillow-laces. *Alençon point* has two threads twisted round a perpendicular, with octagon and square meshes alternately.

The best Brussels lace excels all others in delicate fineness, and in elegance and variety of design. It is made of flax grown near Hal and at Rebecque; and the spinning is performed in darkened rooms, with a beam of light admitted only upon the work through a small aperture. The best specimens are produced by the firms of Tardent-Poilet, and Ducpetiaux, of Brussels. In former days, when Mechlin and Brussels lace often descended as heir-looms from mothers to daughters, the manufacture was confined to lace from the finest thread that could be prepared from flax; and neither time nor expense was spared in that preparation. There is now, however, a great deal of cotton worked up in the Belgian lace of medium and inferior quality. In 1856-7-8, Belgium exported nearly as much cotton lace as flax and silk lace, about a value of 100,000*l.* of each, chiefly to France. This cotton-lace, however, is mostly of the character of machine-made bobbin-net; for real pillow-lace is seldom made of other materials than flax or silk.

Besides the description above given, of the different numbers of threads and forms of mesh, the kinds of foreign lace present other diversities, which are being influenced a good deal at the present day by the machine-made net of Nottingham. Formerly the ground for Brussels lace was made in strips from one to three inches wide, which were afterwards joined with such admirable ingenuity as to render the line of junction imperceptible. But the slowness of the process rendered the product very costly; trimming-lace of four inches in width often brought ten guineas a yard, and veils were from twenty to a hundred guineas each. Now, however, the beautiful net made by machine at Nottingham is more and more used as a ground in Belgium; the flowers or designs being made on the pillow, and afterwards attached to the ground by the needle. This *appliqué* lace is now largely made, and is gradually superseding the real Brussels point—inasmuch that the old specimens are acquiring the antiquarian value which connoisseurs attach to old pictures and old china, depending quite as much on the rarity as on the excellence. Mechlin lace is all made in one piece, without joining; and its peculiarity consists in a plait-thread surrounding the flowers, so as to give the appearance of embroidery. Valenciennes lace, since about 1835, has been more largely made at Ypres than at the town whose name it bears; the dealers now purchase the handiwork of at least 20,000 persons in and around Ypres. In France it is supposed that 200,000 females are employed in pillow-lace making, earning on an average about a penny an hour. Not only flax and silk, but cotton, wool, and gold and silver thread, are often worked up by them into lace; cotton is increasing in use, relatively to flax. Caen and Bayeux excel in silk-lace piece goods, such as veils, scarfs, berthes,

mantles, robes, and shawls; Chantilly in the more elaborate and costly kinds of silk-lace; Mirecourt in the elegance of designs for very light and open lace in flax-thread; Alençon in the costly fineness of the flax-thread used for making the Alençon point; and Puy in the cheapness of the lace made by 40,000 or 50,000 workers scattered in the neighbouring departments.

In England, pillow-lace making is supposed to have been introduced by some refugees from Flanders, about 1626, in or near Buckinghamshire; and for a long time that county maintained a fair rivalry with France and Flanders. In the counties of Buckingham and Bedford the cottagers are largely employed in this branch of industry. In 1800 the number so employed was estimated at 130,000; but the Nottingham machine-lace has since proved a formidable competitor. The kind called *Honiton-lace* is made by placing a perforated pattern upon a pillow, and working the thread round pins in the same way as other pillow-lace; but the difference is this, that Honiton-lace only consists of flowers and devices, which are afterwards sewn on to net made either by hand or by machine. Seven or eight thousand women and girls are employed in the south-eastern part of Devonshire making Honiton-lace; and as much as two hundred guineas has been given for a dress of this material. In the Midland counties the pillow-lace makers have had an increased demand for black-lace, thereby in part compensating them for the loss occasioned in other ways. *British point*, made near London, is an imitation of Brussels and Honiton-lace. *Limerick-lace* is somewhat similar in character. This branch of industry was founded in 1829, by Mr. Charles Walker, who settled at Limerick, leased a large building, took over with him several lace-workers from England, and taught the art to Irish peasant girls; the pupils were quick in learning and clever in manipulation, and a manufacture has been established, which has greatly benefited the town and neighbourhood. There are now many firms engaged in the trade, one of which employs 500 or 600 hands; the earnings vary from 3*s.* to 8*s.* per week. *Tambour-lace*, made at Coggeshall and other places, is a sort of medium between lace and embroidery.

Machine-lace or Net.—The production of light cross-woven goods, previous to the extraordinary development of the bobbin-net manufacture at Nottingham, was carried on only to a limited extent. *Net* was the generic name for these goods; and according as slight deviations were made in the mode of crossing the threads, so were distinctive names given to the material produced; such as whip-net, mail-net, patent-net, drop-net, spider-net, Paris-net, balloon-net, &c. All these varieties were produced at the loom, with warp-threads stretched horizontally, and weft-threads thrown across by means of a shuttle; and the difference between them depended on the manner in which the warp-threads were made to cross one another, and in which the weft-thread was thrown.

In 1758 Mr. Strutt's machine for Derby-rib hosiery, or lace-work ankles and insteps to stockings, was the first approach towards a machine for lace-making. Morris's eyelet-hole machine, in 1763, by which open-work mitts and gloves were made, was a still nearer approach. Crane's Vandyck stocking-web machine, in 1768, produced flowered and spider nets; and Else and Harvey's pin machine, about the same time, was the foundation for the machines ever since used in France and Austria for making tulle and other kinds of silk net. Frost's point machine, in 1777, consisted of a fine gauze stocking frame which, by a few delicate changes, was made to produce a perfect web of lace, in hexagonal looped meshes—all weft, without any warp threads. This was soon superseded by another which manufactured what was termed *point-net*, invented by Lindley, and afterwards improved by Taylor and Flint. The point-net became so highly approved, that there were no fewer than a thousand machines at work at the beginning of the present century. Next succeeded Dawson's warp-machine, which produced *warp-net* in successful competition with the *point-net*; there was warp as well as weft, and the fabric was made to serve both for hosiery and for lace. Still however the net produced did not afford a good imitation of the bobbin-lace or pillow-lace; and the Nottingham manufacturers threw out every inducement for the development of a machine which should produce such an imitation. At length, in 1809, Mr. John Heathcoat, a stocking-weaver of Loughborough, availing himself of an ingenious principle involved in a machine for making fishing-nets, invented a few years before by Robert Brown, of Nottingham, produced and patented the *bobbin-net* machine, one of the triumphs of modern ingenuity. From this time a new field of industry became opened, into which capital and skill rapidly entered. The traverse-warp machine of Brown, the straight-bolt machine of Morley, the pusher-machine of Mart and Clark, the circular-bolt machine of Morley, and the lever-machine of Leavers, were successive improvements on Heathcoat's bobbin-net machine, involving its main principle, but working it out more effectually. In all of these the warp is beamed. At first it required fifty movements to make one mesh; these have now been reduced to six. No less than 40,000 meshes can be made in a minute.

The main points of difference between the bobbin-net machine and the common loom may be thus stated. In the former the warp-threads are vertical; in the latter they are horizontal. In the former the weft is wound on a brass bobbin so thin as to pass between the adjacent threads of the warp; in the latter it is contained in a shuttle an inch or more in width. In the former the transit of the weft-thread, while

passing between the warp, is at right angles to the plane of the web; in the latter it is parallel with that plane. In the former the successive meshes or intersections are driven up close to those before made, by a series of pointed wires catching in the loops; in the latter they are driven up by the lay or batten. In the former there are sometimes as many as three thousand bobbins or weft-carrying implements to one machine; in the latter there are seldom more than one or two shuttles. In the former each bobbin twists its weft-thread round a warp-thread by a series of oscillatory movements like those of a pendulum; in the latter the twisting is effected rather by the movements

Fig. 1.—Threads twisted into Meshes.

of the warp than those of the weft. What is the kind of work which these machines have to perform will be seen by the annexed cuts; in

which *fig. 1* shows roughly how threads may be twisted to form meshes; while *figs. 2* and *3* show two kinds as actually produced.

Fig. 2.—Rectangular Meshes.

Fig. 3.—Hexagonal Meshes.

Fig. 4 shows the essential parts of the bobbin-net machine, affording some notion of its extreme complexity of action.

Fig. 4.—Essential Parts of Bobbin-net Machine.

The activity to which the invention of the bobbin-net machine gave rise was quite extraordinary, and the profits accruing to the various inventors were at first very large. The productions of the machine superseded the older fabrics by the extraordinary cheapness at which they were made; so that bobbin-net, resembling that for which, in 1809, five guineas a yard were given, is furnished in 1860 for sixpence. [COTTON MANUFACTURE.]

From certain statistical details which Mr. Felkin, of Nottingham, the leading authority on this subject, furnished to the Factory Commissioners about the year 1833, it appears that at that time the quantity of cotton used annually in England for bobbin-net was about 2,387,000 lbs., value about 200,000*l.*; that this was made into thirty million yards of net, value nearly two millions sterling; that 160,000 persons were employed in spinning, doubling, weaving, mending,

pearling, finishing, and embroidering the net; that the fixed and floating capital invested in the bobbin-net manufacture reached as high as two millions sterling; and that there were from four to five thousand bobbin-net machines then in England. Some of these machines produced net twenty quarters or five yards in width. Many of them now have as many as 4500 cards with the Jacquard apparatus [JACQUARD APPARATUS]; and it may with truth be said, that such a machine, with its three or four thousand delicately-constructed brass bobbins, and provided with a Jacquard apparatus, is one of the most exquisite pieces of mechanism which our manufacturers can exhibit.

The hand-workers of the Midland Counties rose in violence against Mr. Heathcoat and his machines; and he went to live at Tiverton, in Devonshire, to be free from interruption. Tiverton, with off-shoots at Barnstaple and Chard, has become the head-quarters for a particular

kind of machine-made silk-net; while machines on Heathcoat's principle have borne down all opposition at Nottingham and elsewhere. They did not, however, drive out the warp machines, which are found to be suitable for a particular class of goods,—blond, edging, net, and lace of silk: tattings, pearl trimmings, net, and lace, of cotton; D'Oyleys, anti-macassars, and other articles of a cheap and durable kind. Mr. Felkin, in 1843, estimated that there were at that time 300 of these machines at work upon silk, 500 upon cotton, 5000 hands employed, and 350,000*l.* worth of goods annually produced, of which 290,000*l.* was available as wages, interest, and profit.

In a later estimate, in relation to the whole trade, Mr. Felkin stated that in 1856 there were 3500 machines making net, many as much as five yards in width, and all averaging three yards. More than half were engaged on fancy net or lace; and of the other half 1300 were rotary circular machines, making plain goods. Many fine large factories had been built at Nottingham since 1850, to work these machines. The returns he set down at about 3,000,000*l.* annually, of which 2,200,000*l.* was divided among the masters and workmen for interest, profit, and wages, leaving the rest for the purchase of raw material. There were 115 wholesale firms in Nottingham alone, engaged in this trade. The cotton-yarn used for net varies from No. 20 to No. 400, the latter of which is so fine that 100 miles of it would barely weigh a pound. We may remark that *quilling*, *tatting*, and *pearl-lace* or *net* are all made in narrow strips.

In the processes of 'lace-running' and 'tambouring,' largely carried on in and near Nottingham, the operation approaches more nearly to a kind of weaving; for the bobbin-net, which forms the ground, is stretched horizontally on a frame, and the lace-runner works a series of ornaments in the net by a needle threaded with coarse cotton, the pattern being previously marked on the net. In the process of 'tambouring' net, the cotton thread is carried to and fro between the meshes of the net by means of a very fine and small hook, which gives to the decorative figure thus produced much more the appearance of chain-work than the instance above noticed. *Figs. 5 and 6 show the*

Fig. 5.—Machine Lace.

Fig. 6.—Run Lace.

difference between machine-lace and run-lace—that in which the device is worked by the machine, and that wherein the device is wrought by a needle on plain net.

Lace-making and net making machines have been introduced into France and Belgium, mostly from England; but Nottingham still continues to be the head-quarters of the trade.

LACHRYMAL ORGANS, DISEASES OF THE. The lachrymal gland is very rarely the seat of disease. It sometimes suppurates from acute inflammation, but it is more commonly affected with a chronic enlargement and induration, forming a prominent tumour under the upper eyelid, which pushes the eye downwards and inwards.

In this state it may be removed without difficulty and with perfect safety from beneath the eyelid.

The most frequent disease of these organs is that commonly called fistula lachrymalis, which consists of inflammation of the lachrymal sac. [EYE, NAT. HIST. DIV.] When the inflammation is acute, it forms a tumour of about the size and shape of a horse-bean at the inner side of the eye, which is firm, red, hot, and extremely painful. The nasal duct being closed, the tears, which should pass through it into the nose, flow continually over the cheek, and produce redness and excoriation. The eyelids swell, and the pain and tension are sometimes so severe as to excite considerable fever and even delirium. If the inflammation be not early checked, suppuration takes place, and the matter may escape by an opening, which sometimes remains for a long time fistulous, at the corner of the eye. The treatment must be actively reducing, and when suppuration has taken place an early opening should be made into the sac at its most prominent part.

In the chronic inflammation of the lachrymal sac, which often succeeds to the acute, the nasal duct continuing obstructed, the sac becomes frequently distended with its secretion, and a mixture of mucous and purulent matter may be pressed out of it through the puncta lachrymalia. In some cases no other inconvenience is produced than that of the necessity of pressing out the contents of the sac once or twice a day; but in others, attacks of acute inflammation are apt to supervene, and excite very painful affections both of the lachrymal apparatus and the eye itself. In the first instance, leeches and other antiphlogistic remedies should be employed; but if they are unsuccessful, astringent lotions should be applied to the eye, that they may be imbibed by the puncta lachrymalia, and conveyed through them to the nasal duct. But if these means fail, the lachrymal sac must be punctured near the inner angle of the eye, and a probe passed through it into the nose. A portion of bougie must be introduced into the passage thus restored; the canal will enlarge around it so as to permit the tears to pass through, and after a few days the bougie may be exchanged for a nail-headed style, which must be worn in the canal and sac for a considerable time.

LACHRYMATORY, a small earthen or glass vessel, generally with a long neck, found in the sepulchres of the ancients. Chifflet, in his 'Lachrymæ prisco ritu diffusæ,' first started the idea that they were intended to hold the tears of relatives or friends, who assisted at the funeral rites; and the notion was long supported by the antiquaries of different countries throughout Europe. It was afterwards combated by Schœpflin and Paciaudi, and as no such use of these phials or little bottles can be discovered in passages of the Roman writers, the conclusion was at length come to that they were intended to contain perfumes or balms only for sprinkling upon the funeral pile.

LACQUERING. [JAPANNING; VARNISH.]

LACTAMIC ACID. [LACTIC ACID.]

LACTAMIDE. [LACTIC ACID.]

LACTIC ACID (from *lacte*, milk) ($C_{12}H_{12}O_{12}$) is the substance that gives the well known acidity to sour milk. It is produced from the milk-sugar by the fermentive action of the casein or cheese portion. This acid is also met with in many other processes where starches or sugars other than milk-sugar are undergoing fermentation. It occurs in the fluids of the muscular tissue. When required in quantity lactic acid is most conveniently prepared by adding one part of common cheese to a solution of eight parts of milk-sugar in about fifty of water, stirring in three parts of powdered chalk and setting the whole aside for two or three weeks in a warm place (80° Fahr.). The mixture slowly becomes filled with crystals of lactate of lime, these are separated by straining, purified by re-crystallisation from water, decomposed with about one-third of their weight of sulphuric acid, and the liquor, freed from the sulphate of lime by filtration, is decolorised by treatment with animal charcoal, and concentrated by evaporation.

Lactic acid is uncrystallisable. When pure it has the consistence of strong syrup, is transparent, colourless, inodorous, of intensely acid taste, and has a specific gravity of 1.21. Exposed to the air it absorbs water, in which it is soluble in all proportions. It is also very soluble in alcohol and ether. An exceedingly minute quantity of it at once causes the coagulation of boiling milk. Nitric acid converts it into oxalic acid. By careful application of heat to lactic acid, contained in vessels from which air is excluded, it may be distilled; but at a temperature of 500° Fahr. is converted into carbonic acid, aldehyd, citraconic acid, lactide ($C_{12}H_8O_8$), and lactone ($C_{10}H_8O_4$). By the continued action of a heat of about 266° Fahr. lactic acid is gradually converted into lactic anhydride ($C_{12}H_{10}O_{10}$), a fusible, bitter substance of yellow colour, insoluble in water, but gradually re-converted by prolonged contact with that liquid into lactic acid.

Lactone ($C_{10}H_8O_4$) is a pungent volatile liquid. Boiling point 198° Fahr.

Lactide ($C_{12}H_8O_8$), obtained in the manner just described, crystallises from alcohol in clear white rhomboidal tables. It may be sublimed without undergoing decomposition. Water gradually converts it into lactic acid, and ammonia forms with it lactamide.

Lactamide ($C_3H_7N_2O_3$) is also obtained by the action of lactic acid on ammonia. It is interesting as being identical in composition with three other bodies, alanine, sarcosine, and urethane (carbamate of the oxide of ethyl). They have all of them, however, very distinct properties. This substance differs from the others in yielding lactic acid and ammonia when acted on by acids and bases; hence its name. It is very soluble in alcohol and water, and crystallises in plates or prisms.

Lactamic acid, in combination with ammonia, results from the action of the dry gas upon lactic anhydride. The salt contains ($C_{12}H_{12}(NH_4)NO_{10}$).

Metallic derivatives of lactic acid. One or two equivalents of the hydrogen in lactic acid may be replaced by one or two equivalents of metal forming respectively acid and neutral salts; the latter are more stable than the former. The salts of the alkalis do not crystallise; those of baryta and lime with difficulty; that of zinc (neutral) in four-sided prisms.

The true constitution of lactic acid is not yet clearly determined. Wurtz has recently succeeded in obtaining a lactic ether which may be said to contain four equivalents of ethyl in the place of an equal number of hydrogen in lactic acid. Wurtz, however, considers that lactic acid is the alcohol of a biatomic radical *lactyl* ($C_6H_4O_2$), and is thus formulated:

In addition to lactic ether just mentioned, Wurtz has obtained lactobutyric ether by the re-action of *chlorolactic ether* ($C_6H_4O_2$, C_4H_5 , Cl , O_2) on butyrate of potash. The following are his formulæ for these two ethers:—

Corresponding metallic derivatives are said to have been produced but not without difficulty in the case of the second atom of hydrogen in the lactic acid as represented by Wurtz. Those containing one atom only of hydrogen replaced correspond to the salts already mentioned under the name of neutral salts of lactic acid; while the acid salts described at the same place would, under Wurtz's view, somewhat resemble quadroxalates, and be derived from a double equivalent of his lactic acid by substitution of an atom of metal for one of hydrogen.

LACTIC ETHER. [LACTIC ACID; ETHEREAL SALTS.]

LACTIDE. [LACTIC ACID.]

LACTIN. [SUGAR; *Sugar of Milk.*]

LACTOBUTYRIC ETHER. [LACTIC ACID.]

LACTONE. [LACTIC ACID.]

LACTOSE. [SUGAR; *Sugar of Milk.*]

LACTUCARIUM, the medical uses of, are sufficiently described under this head in the NAT. HIST. DIV.

LACTUCINE is the active principle of the *Lactuca virosa*, or wild lettuce. It is obtained from the juice of this plant, which is called *Lactucarium*. It is a bitter, crystalline, resinoid substance, possessing anodyne properties.

LACTUCONE ($C_{30}H_{64}O_6$). A crystallisable principle contained in the juice of the wild lettuce (*Lactuca virosa*). It is insoluble in water, but very soluble in alcohol and ether. It possesses neither acid nor alkaline properties.

LACTYL. [LACTIC ACID.]

LADANUM. ($C_{40}H_{30}O_6$). A resinous body which exudes from the shrub *Cistus creticus*. It is a black tenacious solid which softens between the fingers and diffuses an odour resembling ambergris.

LADDER, the portion of a scaffolding by means of which workmen are enabled to pass from one level to another; and any steep staircases, with extremely narrow treads, such as are used in mines, factories, or warehouses, or even in ships' holds, are known by the name of ladders. The principal distinction between ladders and staircases appears to consist mainly in this—namely, that with staircases there is no necessity for using the hands whilst mounting or descending, whereas with ladders it would not be possible to maintain a footing without at the same time holding either the sides, or the rounds, with the hand. The parts of a ladder are, simply, the *sides*, which are usually made of round fir-poles cut down the middle (and in England used with the convex sides outwards, whilst on the Continent the flat transverse sections are placed outwards); the *rounds*, usually made of oak, of a circular section, rather larger in diameter in the middle and tapering towards the sides, and fastened to the said sides by fox-wedges; and occasionally iron cross-ties are inserted, in order to resist any tendency on the part of the sides to spread. The distance apart of the rounds varies from nine inches to one foot, but ten inches is the distance most generally adopted, for scaffolding at least.

There are some modifications of ladders used in particular trades, such as the plasterers' or painters' ladders, made out of wrought and squared stuff, and with hinges at the top; and upholsterers' step-ladders, which have hinged flaps at the backs and flat treads. Millers' ladders have flat treads, and sometimes handrails on the outside; but

they, and the companion ladders of ships, ought more correctly to be classed as staircases. The chain of buckets of a dredging-machine is also at times called a "ladder."

In the cathedral of Nuremberg the idea of the ladder has been admirably converted into an architectural decoration in the details of the canopy of the pulpit; and it may indeed be observed, that story of the ladder perceived by Jacob in his dream is one which would have very probably suggested its introduction into ecclesiastical decoration. The designer and sculptor of the Nuremberg pulpit was Adam Kraft, who flourished about the end of the 15th century.

LADING, BILL OF. [BILL OF LADING.]

LÆVORACEMIC ACID. [TARTARIC ACID.]

LÆVOTARTARIC ACID. [TARTARIC ACID.]

LAGOON, or LAGUNE. Lagoons are sheets of water formed either by the encroachments of rivers or seas upon the land, or by the separation of a portion of the sea by the intervention of a bank. Thus there are fluvial and marine lagoons. When the land on either side of a river's course is lower than the immediate banks of the stream, and the river, in the season of the floods, either overflows its banks or in part breaks them down, the water inundates the low land; and if on the subsidence of the flood the water again flows back into the channel, the lagoon is merely temporary, and is simply an inundation. This, according to circumstances, may be a benefit to the country or a disaster. Inundations are a benefit when they bring with them and deposit a rich vegetable humus, which, on being cultivated, yields abundant crops; to such deposits Lower Egypt owes its great fertility. Inundations of this kind either diminish or increase annually, for, by repeated deposits, the soil becomes raised; and unless the bed of the river rise in proportion, the water is eventually kept within its channel; but if, on the contrary, the bed rise, the inundation gains every year in extent of surface what it loses in depth of water. Should the inundation however, instead of a prolific mud, bring nothing but sand and stones, then, as has been frequently experienced in Italy, the inundations are a cruel disaster, for they condemn rich lands to eternal barrenness and sterility. If the configuration of the land and other circumstances prevent the water of the inundated parts from flowing back on the subsidence of the flood, then a permanent lagoon is formed, and the land thus laid under water can only be recovered at a great expense, even if that be possible. These lagoons are generally fatal to the neighbourhood, for the water in them, being stagnant, gives rise to unwholesome miasmata, producing agues and other malignant disorders. Such lagoons are not absolutely confined to the lower parts of water-courses, though it is in such places that they are most frequently met with. Fluvial lagoons are sometimes formed by infiltration; a remarkable instance of which is the marshy lagoon of Ybera, on the Parana, in South America.

Marine lagoons are much more common than those on the borders of rivers. They are formed sometimes by the encroachments of the sea, and sometimes by the throwing up of a bar or bank, which eventually divides off a portion of the sea altogether, or leaves merely a small opening. In Europe there are many marine lagoons; the Adriatic, on its north and north-western parts particularly, is full of them. The Zuyder Zee is a vast lagoon. There are also two very large ones known by the names of the Frische Haff and the Curische Haff, at the south-east angle of the Baltic Sea. In the Sea of Azoff there is the Sivasch or Putrid Sea. On the east coast of South America there are some very large lagoons, and they abound at the bottom of the Mexican Gulf. Marine lagoons can never be useful unless when sufficiently large and deep to admit of being navigated, in which case they form secure harbours. When shallow, they give out foetid exhalations like fluvial lagoons, as is too well known in Venice, which is built on the 60 islands of the lagoon at the extremity of the gulf; though in this case much of the evil arises undoubtedly from the circumstance of the lagoon being the receptacle of all the filth of the city.

LAITY, persons not clergy; that is, the whole population except those who are in holy orders. All the lexicographers, we believe, agree in deriving it from the Greek word *laos* (λαός), the people. A *layman* is one of the laity. The terms are not used except when the mind is directed to the distinction of the two classes.

LAKES. [COLOURING MATTERS.]

LAKES are in the land what islands are in the sea; they are surrounded on all sides by land, as islands are by water. They are sheets of water of greater or less extent, and differ from lagoons in their origin, and from tanks and reservoirs by their being naturally formed, whereas the latter are the works of man. From ponds and pools it is not so easy to distinguish them, it being difficult to draw the line between a large pond and a small lake. The feature by which perhaps they would be best distinguished is this, that a lake is fed by streams either flowing at the surface of the soil or subterranean, while a pond, though large, is only the accumulation of rain-water in some hollow. Thus ponds are usually dried up in hot weather, while true lakes are only temporarily diminished by heat.

Lakes have sometimes been divided into fresh-water lakes and salt-water lakes; though here again it is not easy to draw the line between the two, as from the freshest to the most salt the degrees of saltiness are very various.

The principal difference in lakes is this: some have no apparent

affluents nor outlet, others have affluents without any visible outlet, some have an outlet without any visible affluents, and others again have both affluents and an outlet. Lakes without outlets have the level of their waters horizontal, that is, parallel to the curvature of the earth; while those with affluents and outfalls are on the contrary more or less out of the horizontal level, sometimes, as in the Lago Maggiore, as much as three inches in a mile.

Lakes without apparent affluents or outlets are comparatively small, and yet they are, relatively speaking, more permanent than larger lakes, because, being fed chiefly by subterraneous springs, they are not liable to be filled by those deposits of earth and sand which are the main cause of the rapid desiccation of such lakes as receive the troubled waters of torrents and rivers. If we follow the usual custom and call all natural sheets of water lakes, then there are many lakes without affluents or outlet. Thus they are very numerous to the northward of the Caspian and in the plains which extend between the Ural Mountains and the Irtysh, as also in the great Steppe of Baraba between the Irtysh and the Ob. But in truth the greater part of these are more properly ponds, formed of the accumulated waters from rain and melted snow. The largest of them are not more than ten or twelve miles in circumference and six or seven feet deep; indeed many of them are quite dried up towards the end of summer. Some are salt and yield considerable profit. Their saltiness is not easily accounted for; the more particularly as among and close to those that are salt there are many whose waters are quite fresh. The opinions of naturalists on the subject of salt lakes are very various, and no satisfactory theory has perhaps yet been offered. Small lakes of the kind of which we have been speaking, that is to say, such as have neither affluents nor outlet, sometimes occur in hollows resembling the craters of extinct volcanoes. There has been much controversy as to the existence of lakes in volcanic rocks. Dolomieu, Spallanzani, and others, asserted their existence, while M. Desmarest absolutely denies the possibility of lakes existing in the craters of extinct volcanoes. But near the present active volcano of Antuco (in the state of La Plata, not far from Mendoza), there is a lake of immense depth, at a height of from 4000 to 5000 feet above the sea, which has such an intimate relation with the volcano, that on every eruption the lake pours out a stream of muddy water, wasting the adjacent district. The little lake of Nemi, about 20 miles from Rome, is unquestionably formed in an old volcanic crater, and that it has increased since its first formation, is shown by its having engulfed a building of the time of Tiberius. The celebrated lake of Averno is, according to Ferber and Breislak, situated in an ancient crater; as were those probably of Bolsena and Bracciano. The subject of lakes, considered geologically, has not yet received the attention it deserves. The connection of lakes with the main ocean is an important but little known question. They are all basins enclosed by certain obstructions that act as dams, and which certain phenomena, such as earthquakes or volcanoes, may destroy, and allow the water to run off. London, there is every reason to suppose, stands on the site of what was once a lake of large size.

Of lakes which receive affluents without having any visible outlet, the largest is the Caspian. The Aral, and the Dead Sea, or Lake Asphaltites, are also examples of this kind of lake, which is very common in Asia. Some of them are of vast extent, such for instance is the lake Terkiri in Tibet, 27 leagues long and 9 leagues wide, and the lake Hoho-nor, or Koko-nor, in the same country, whose surface is 240 square leagues. It was at one time thought that the saltiness of certain lakes was due to the circumstance of their receiving the saline impurities of their affluents, which impurities could not escape for want of an outlet; but on the one hand, the Durrah in Segistan, which receives the Helmund and has no outlet, is perfectly fresh; and on the other, there are many salt lakes which have no affluents, hence the saltiness of lakes must have some other cause. The question has sometimes been asked, what becomes of the excess of water brought into lakes having no outlet? Halley thought evaporation was all-sufficient to carry it off, and his opinion is highly plausible. If, however, it shall be found by actual experiment that a greater quantity of water is brought into a lake without apparent issue than can be carried off by evaporation, the natural conclusion will be, that the surplus is lost by infiltration or sub-aqueous drainage. Several of these lakes have formerly had outlets, but water has ceased to flow from them, because the lakes have sunk in consequence of receiving now a much smaller quantity of water than formerly. There are many lakes in Europe at the present day whose outlets are diminishing; such among others are the lakes Balaton and Neusiedel in Hungary. The extent of surface of the former is very great compared with the quantity of water which it receives, so that the evaporation is rapidly diminishing the lake, and the river Schio, which used to carry off its superabundant waters and pour them into the Danube, is now nothing more than a slip of bog; and as for the lake Neusiedel, it appears formerly to have communicated with the Danube by the Raab, into which it emptied its waters, and with which it has now no other communication than by a swamp. The Aral also, it is generally believed, once communicated with the Caspian.

Those lakes which have an outlet without any apparent affluent are fed by subaqueous springs, which, bursting out in a hollow, must fill it up before the waters can flow off in a stream. These lakes are generally situated at considerable elevations above the level of the sea.

Thus there is one on Monte Rotondo in Corsica, at an elevation of 9069 feet. From lakes of this kind some of the largest rivers take their rise; the Volga, for instance, springs from such a lake in the government of Tver in Russia. The lake Titicaca in the Bolivian Andes, is 12,000 feet above the sea-level, and is 120 fathoms deep, while the Caspian is below the sea-level, according to some, 100 feet. The surface of Lake Superior is 600 feet above the sea-level, and in certain places the lake has a depth of 1200 feet; while not only this but all the other Canadian lakes show evident marks of their level having been originally considerably higher, and that they have been lowered by degrees. Lake Erie has a medium depth of only 60 to 70 feet, and the shallowness there is little doubt is owing to the detritus brought down from the lakes above, and there deposited.

Lakes which receive one or more tributary streams and have a visible outlet for their superabundant waters are the most common and the largest; such are the lakes of Switzerland and of the north of Italy, the lakes Ladoga, Onega, Peipus, and Ilmen in Russia; the Saima in Finland, the Wener in Sweden, the Enara in Lapland, &c. In Asia there are the Nor-Zaïssan and the Baikal, &c. In Africa the existence of large lakes in the interior has been well established; first, by the precise verification of lake Tchad, whose outfall is the Niger; and more lately by the discoveries of Dr. Livingstone of the Ngami, of which the great outfall is the Zambezi; by Captain Speke of the lake Nyassi, or Nyanza, which is considered by him as the true source of the Nile. In North America, Lake Superior, Lake Huron, Lake Erie, and Lake Ontario are examples of this kind of lake; each of them receives several affluents; and the grand outlet of the whole is the river St. Lawrence.

Lakes owe their origin to different circumstances: some from the sinking of the soil by the falling in of subterraneous caverns—such is the supposed origin of the Baikal; others are caused by earthquakes—such a lake was formed in the province of Quito in 1797; some by the fall of mountains, as the Oschenen-see in the canton of Berne; or by lava currents damming up the stream, as the lakes Aidat and Cassiere in Auvergne, in France. Many are supposed to be the remains of the universal ocean which once covered the earth, and their waters originally salt, have become fresh from their receiving constant supplies of fresh water while the salt was continually let off by their outlets.

Almost all lakes are in progress of diminution, although this is not everywhere apparent. The detrital matter brought in by their affluents is imperceptibly filling up their beds; and if regular observations were made, many provinces which owe much of their prosperity to their lakes, would find the time fast approaching when these pieces of water will become mere pestilential marshes.

Certain lakes exhibit remarkable phenomena: thus some have floating islands in them, as is the case with a small lake near St. Omer. The lake Gerdau, in Prussia, has a floating island, on which a hundred head of cattle may be seen pasturing. In the lake Kolk, in Osnabrück, there is a floating island, on which fine elms are growing. Some of these floating islands sink and rise again; thus in the lake Rålang in Smoland, a province of Sweden, there is a floating island which appeared and disappeared ten successive times between the years 1696 and 1766. Other floating islands are found in East Gothland and many other places. Some subterranean lakes are supposed to have become so by the formation and subsequent fixing of floating islands, which successively uniting have finished by forming a solid crust over the water.

Some lakes have a double bottom, which rising and sinking alternately changes the apparent depth of the lake; there is a lake of this kind at Jemtia in Sweden.

Some lakes are said to have no bottom; but this is an impossibility: the fact is, that the sound does not reach the bottom, either for want of sufficient weight of lead or length of line, or else it is carried away by under-currents.

In Poland there exists a lake said to render brown the skin of those who bathe in it. Certain mineral waters impregnated with sulphuretted hydrogen are well known to change from white to brown the skins of those persons who have been under a course of metallic medicines, or who use metallic cosmetics, and some such circumstance may be the case with the lake in question.

Some lakes are intermittent: the most remarkable of this kind are those of Cirknitz in Illyria, and Kauten in Prussia. They are supposed to be occasioned by a play of natural siphons, upon the same principle as intermittent fountains.

The Lake of Geneva is subject to a subaqueous wind, called the *Vaudaise*, which, rising to the surface, produces an agitation of the water which is sometimes dangerous to the navigation of the lake. Near Boleslaw in Bohemia there is a lake of unknown depth, from the bottom of which there rise, in winter, such violent puffs of wind, that they are said to send up into the air masses of ice of several hundred pounds weight. The sudden escape of gases formed in the bowels of the earth, and perhaps the air forcibly driven out from caverns by the water rushing into and filling them up, may be among the causes of this remarkable phenomenon.

The *Seiches* are a phenomenon which has hitherto been observed only in the Lake of Geneva and some other of the Swiss and Italian lakes, though it is probably common to many others. It consists in an occasional undulation of the water, something like a tide wave, which rises occasionally to the height of 5 feet. Its cause is not exactly

known, though it is most probably due to a local and temporary change of atmospheric pressure. Water-spouts are a phenomenon sometimes seen on lakes as on the sea; they have been observed on the lakes of Zürich and Geneva.

Certain lakes seem to be placed in the immediate neighbourhood of centres or foci of electrical attraction; thus in the lake Huron there is a bay over which electrical clouds are perpetually hovering. It is affirmed that no person has ever traversed it without hearing thunder. The proximity of this lake to the American magnetic pole, that is, to the spot where the magnetic intensity is greatest, not where the dip is greatest, may perhaps have some influence in producing so remarkable a phenomenon.

Near Beja in Portugal there is a lake which is said to announce the approach of a storm by a tremendous rumbling. In Siberia also, near the little river Orcibat, which flows into the Abakan, there is, according to Pallas, a lake called the Roaring Lake, from the dreadful noise it makes, and which announces internal revolutions similar to that which occasioned the rupture of the dykes of the Lake Goussmoï in Douaria.

Some lakes have been observed to possess a petrifying or an incrusting property. The latter is merely a deposition of carbonate of lime. This, being dissolved by an excess of acid in the waters of certain springs, is precipitated whenever the waters of these sources coming into the lakes are exposed to the air and lose their excess of acid.

There is an interesting phenomenon presented by the Lake of Zürich, called the flowering of the lake. When this takes place the surface of the water is seen covered with a yellow scum or froth, which upon examination is found to be a very minute vegetation.

There are various other phenomena presented by lakes, but the most singular of them all perhaps is the attractive force of the mud at the bottom of some lakes, which is such that boats can hardly make their way through the water. The Lake Rose and one or two more in Canada are of this kind. Mackenzie describes the fact in these words:—"At the portage or carrying-place of Martres, on Rose Lake, the water is only three or four feet deep, and the bottom is muddy. I have often plunged into it a pole twelve feet long, with as much ease as if I merely plunged it into the water. Nevertheless this mud has a sort of magical effect upon the boats, which is such that the paddles can with difficulty urge them on. This effect is not perceptible on the south side of the lake, where the water is deep, but is more and more sensible as you approach the opposite shore. I have been assured that loaded boats have often been in danger of sinking, and could only be extricated by being towed by lighter boats. As for myself, I have never been in danger of foundering, but I have several times had great difficulty in passing this spot with six stout rowers, whose utmost efforts could scarcely overcome the attraction of the mud. A similar phenomenon is observed on the lake Saginaga, whose bottom attracts the boats with such force that it is only with the greatest difficulty that a loaded boat can be made to advance; fortunately the spot is only about 400 yards over." Captain Back has confirmed the above by later observations.

Lakes differ very much in temperature, transparency, and in the colour of their waters. Lakes fed by the water of melted snows in summer are generally much colder than would be thought conformable with the season; but the difference is principally in the lower waters, which, being cold, remain at the bottom by reason of their greater density. Some lakes never freeze, which is owing to their great depth. This is the case with Loch Ness in Scotland, which is 810 feet deep in the deepest part. Lakes are not subject to tides; at least the amount of tide, so far as observation goes, seems not to be ascertained.

The remarkable transparency of certain lakes is truly astonishing; thus the waters of Lake Superior are so pellucid, that, according to Mr. Heriot, the fish and rocks may be seen at a depth incredible to persons who have never visited these regions. The density of the medium on which the vessel moves appears scarcely to exceed that of the atmosphere, and the traveller becomes impressed with awe at the novelty of his situation. Elliot, in his 'Letters from the North of Europe,' says, "Nothing appears more singular to a foreigner than the transparency of the waters of the Norwegian lakes. At the depth of 100 or 120 feet, the surface of the ground beneath is perfectly visible; sometimes it may be seen wholly covered with shells, sometimes only sprinkled with them; now a submarine forest presents itself to view, and now a subaqueous mountain." In the lake Wetter, in Sweden, it is said a farthing may be seen at the depth of twenty fathoms.

With regard to the colour of lakes, it may be observed that it is sometimes very difficult to account for the tints of large masses of water. The colour of the bottom, the depth, the shadows and reflected colours of surrounding bodies, subaqueous vegetation, springs, and many other circumstances, affect the colour of lakes.

Lakes perform a very important function in the economy of the earth. Rain does not always fall, and were it not for lakes, both visible and subterranean, those great natural reservoirs, the greater number of rivers would be dried up in summer, and canals could not have a constant supply of water. The freshness and humidity which these sheets of water occasion by their evaporation are also eminently favourable to the vegetation in their environs. Many lakes are of sufficient extent to be navigated, and thus facilitate commerce and industry. The fisheries of some are very valuable, and others, by the salt obtained from them, are a mine of wealth. Finally, they most

agreeably diversify the surface of the earth by the various appearances which they present of the beautiful and the sublime.

LAMA, LAMAISM, is the name given to the Buddhist religion in Mongolia and Tibet. Lama in these languages properly means priest, but is only applied to those persons who enjoy the higher dignities of the Buddhist hierarchy. It first became an illustrious appellation after the conquests of the Mongols under Genghis Khan and his successors had elevated the individual who pretended to be the successor of Buddha to the dignity of Dalai Lama. The name was first confined to eight subordinate chiefs, who were appointed to act as his council, but was afterwards extended by the Dalai Lama to all other priests who possessed a certain degree of authority. The title of Lama is given to the head of every monastery, and every Lama is considered a vicar of the deity, and requires implicit obedience to all his commands, like the Dalai Lama himself. The opinions of this sect are fully developed in the article BUDDHA; and their religious rites and ceremonies resemble those of the BONZES in Japan.

M. Huc ('Souvenirs d'un Voyage dans la Tartarie, le Thibet, et la Chine, pendant les années 1844, 1845, et 1846,' Paris, 1850), says the Lamas of Tibet are persons of the most limited information, and that their creed is little more refined than that of the vulgar.

The Lamas of Tibet are the physicians; they cure by prayers and some insignificant medicament.

At the Lamasery of Tchort-chi there are 2000 Lamas: it is a favoured place of the emperor, and in it the Mantchou language is taught.

The death of a Grand Lama, says M. Huc, occasions no visible grief or mourning, they only consider the death as a disappearance, and with fasting and prayer the Lamasery await the announcement of his re-appearance. This is revealed by certain augurs, who inform the disciples when and in what place a child will be found in whom the new Buddha has taken up his abode. When found, the child, usually about five or six years old, is examined as to the circumstances of his recent death, and of the events of his previous existence; the answers are usually satisfactory; he is conducted in grand procession to the Lamasery, and becomes at once the Grand Lama of the particular Lamasery, for there is no Tartar kingdom which does not possess in one of its chief Lamaseries a living Buddha.

In all the great Lamaseries are placed barrel-like figures, formed of a number of sheets of paper pasted together, into a thick board, and turning on an axle. On these sheets of paper are written the most usual prayers of the district; and those who want the power or the will to perform long and tedious ceremonies, set this barrel in motion, by which the same effect is produced—the praying and the prostrations are done for them.

LAMIAN WAR. Those cities of Greece which were impatient under the supremacy of the Macedonians regarded Alexander's death as a favourable opportunity to regain independence. In this struggle the Athenians took the lead. They were cordially supported by the Ætolians, both having a private reason for their alacrity in Alexander's avowed design to restore all Greek exiles to their countries. By such a measure the Athenians would have been obliged to cede Samos, part of which they had lately colonised to the expulsion of the former possessors, while the Ætolians had a similar motive in their treatment of Ceniadæ. The richer part of the Athenians were very averse to contend again with the power of Macedon; but the poor, who looked to war for pay and plunder, of whom Philip said that war was their peace, and peace their war, carried the point, and ambassadors were despatched through Greece to organise a confederacy, in which the Argians, Messenians, and other states of Peloponnesus, with many of the minor nations of northern Greece, joined. The events of this, which is called the Lamian War, will be found under ANTIPATER and LEOSTHENES, in the BIOG. DIV.; and ATHENS, in the GEOG. DIV.

LAMMAS DAY, the name for the first of August, from the Anglo-Saxon *Hlaf-mæsse*, loaf-mass or feast, when the Saxons offered an oblation of loaves made from new corn; other derivations have been given, as Lamb-mass, from the tenants of the see of York having been bound to bring a live lamb into the church at high mass. Brand in his 'Popular Antiquities' speaks of it as still a usage in some places for tenants to be bound to bring in wheat of the year to their lord on or before this day. In the Salisbury Manuals of the 15th century it is called "*Benedictio novorum Fructuum*." This day had also the name of the Gule of August, as Pettingal ('Archæologia,' vol. ii. p. 67) says from the Celtic *Wyl*, or *Gwyl*, a festival. This was the day (the festival of St. Peter's ad Vincula) on which Peter-pence was paid in England while Popery was established.

LAMP-BLACK is a variety of carbon; it is characterised by a total absence of crystalline structure, and by its exceedingly minute state of division. It may be prepared by burning organic matters rich in carbon, with an imperfect supply of air, and providing means for collecting the dense smoke or soot produced. Inferior varieties of resin are sometimes employed as a source of lamp-black, but the material generally made use of is coal-tar. The latter substance, purified to a certain extent by the action of lime and steam, is supplied from a heated main-pipe to a series of small jets, each furnished with a wick, and ignited. Over each burner is fixed a small hood into which the dense smoke passes, and being conveyed along successive series of coarse canvas bags connected together by pipes, deposits its soot or lamp-black on their sides. After the operation has continued for some days, the

deposit is shaken to one end of the bag and removed, and the mouth of the bag again tied up.

Lamp-black is largely used as a pigment, chiefly in the manufacture of printers' ink. It always retains a small quantity of undecomposed hydrocarbons.

LAMP. [LIGHTS, ARTIFICIAL.]

LAMP, MONOCHROMATIC. If common salt be dissolved in spirits of wine the mixture will burn with a yellow flame, and if no other lights be burning at the same time, the effects will be extraordinary. An arrangement for furnishing the lamp with a regulated supply of the prepared spirit is termed a *monochromatic lamp*.

LAMP, SAFETY. It has long been known that coal-mines, and especially such as are deep, are occasionally infested with carburetted hydrogen, a gaseous product, which, on account of its combustible property is called *fire-damp*; the word being the equivalent of the German *dampf*, a vapour or exhalation.

Several contrivances had been proposed for safely lighting coal-mines subject to the visitations of this gas; but the safety-lamp of Sir H. Davy was the first one extensively employed. Davy began a chemical examination of various specimens of fire-damp, by which he confirmed the previous statement of Dr. Henry, that the pure inflammable part of it is carburetted hydrogen gas. He found that it required an admixture of a large quantity of atmospheric air to render it explosive. Proceeding with his experiments Davy ascertained that explosions of inflammable gases are incapable of being passed through long narrow metallic tubes; and that this principle of security is still obtained by diminishing their length and diameter at the same time, and likewise by diminishing their length and increasing their number; so that a great number of small apertures would not pass explosion when their depth was equal to their diameter. This fact led to trials upon sieves made of wire gauze. He found that if a piece of wire gauze was held over the flame of a lamp, or of coal gas, it prevented the flame from passing; and he found also that a flame confined in a cylinder of very fine wire gauze did not explode even a mixture of oxygen and hydrogen, but that the gases burnt in it with great vivacity.

The experiments to which we have now alluded, served as the basis of the safety-lamp, which Davy described as follows: "The apertures in the gauze should not be more than $\frac{1}{32}$ of an inch square. As the fire-damp is not inflamed by ignited wire, the thickness of the wire is not of importance; but wire from $\frac{1}{10}$ to $\frac{1}{60}$ of an inch in diameter is the most convenient. Iron-wire and brass-wire gauze of the required degree of fineness are made for sieves by all wire-workers; and except when a lamp is to be used by a viewer for dialling, iron-wire gauze is to be preferred: when of the proper degree of thickness it can neither melt nor burn; and the coat of black rust which soon forms upon it superficially, defends the interior from the action of the air. The cage or cylinder should be made by double joinings, the gauze being folded over so as to leave no apertures. When it is cylindrical it should not be more than two inches in diameter; for in larger cylinders the combustion of the fire-damp renders the top inconveniently hot; and a double top is always a proper precaution, fixed at the distance of half or three-quarters of an inch above the first top. The gauze cylinder should be fastened to the lamp by a screw of four or five turns, and fitted to the screw by a tight ring. All joinings in the lamp should be made with hard solder; and the security depends upon the circumstance that no aperture exists in the apparatus larger than in the wire gauze."

The annexed figure of the safety-lamp requires but little explanation. The cylinder of wire gauze is defended by three upright strong wires, which meet at the top; and to them a ring is fixed, from which the instrument is suspended. The lamp is screwed on to the bottom of the wire gauze, and is supplied with oil by the pipe projecting from it. A wire, bent at the upper end, is passed through the bottom of the lamp for raising, lowering, or trimming the wick. When the lamp is lighted and introduced into an atmosphere gradually mixed with fire-damp, the first effect of the fire-damp is to increase the size and length of the flame. When the inflammable gas forms as much as $\frac{1}{12}$ of the volume of the air, the cylinder becomes filled with a feeble blue flame; but the flame of the wick appears burning brightly within the blue flame. The light of the wick continues till the fire-damp increases to one-sixth or one-fifth, when it is lost in the flame of the fire-damp, which in this case fills the cylinder with a pretty strong light. The operation of the wire gauze in preventing the communication

of flame is thus explained:—Flame is gaseous matter so intensely heated as to be luminous. When the flame comes into contact with wire gauze it loses so much heat in consequence of the conducting power of the metal, that it is cooled down below the point at which

gaseous matter can remain luminous; and consequently the flame of the gaseous matter burning within the lamp is incapable of passing through it so as to set fire to and explode the mixture of fire-damp. This cooling power is exerted even though the wire gauze, by effecting it, be rendered red-hot.

Although the inventor of this lamp expressed himself fully satisfied of its security, yet others have entertained strong doubts on the subject. During the session of parliament for 1835 a committee was appointed to inquire into the Accidents in Mines. The evidence of Mr. Buddle was strongly in favour of the safety of the lamp; he stated, that for many years he had had not less than 1000, and sometimes 1500 lamps in daily use, and that he never knew in one solitary instance an explosion to happen from them; and he mentioned also that he had been with them in all possible varieties of explosive mixtures. On the other hand abundant evidence, and especially that of Dr. Pereira, was adduced before the committee to show, that in strong currents of explosive mixtures the lamps could not be trusted, as the flame passed through them; indeed Sir H. Davy seems himself to have been aware that an objection might possibly be urged against them on this head, and he proposed the use of a tin shield where such currents occur. Dr. Turner remarks:—"If a lamp with its gauze red-hot be exposed to a current of explosive mixture, the flame may possibly pass so rapidly as not to be cooled below the point of ignition; and in that case an accident might occur with a lamp which would be quite safe in a calm atmosphere. It has been shown by Messrs. Upton and Roberts, that flame may in this case be made to pass through the safety-lamp as commonly constructed; and I am satisfied, from having witnessed some of their experiments, that the observation is correct. This then may account for accidents in coal-mines where the safety-lamp is constantly employed. An obvious mode of avoiding such an evil is to diminish the apertures of the gauze; but this remedy is nearly impracticable from the obstacles which very fine wire gauze causes to the diffusion of light. A better method is to surround the common safety-lamp with a glass cylinder, allowing air to enter solely at the bottom of the lamp through wire gauze of extreme fineness, placed horizontally, and to escape at top by a similar contrivance."

In mentioning the names of other inventors of safety-lamps, we must especially allude to the late George Stephenson; because some injudicious friends of Davy have sought to brighten the fame of that great chemist by disparaging the self-taught engineer. In 1815 Stephenson was engine-wright at the Killingworth Colliery, near Newcastle. Terrible explosions having taken place, he turned his ingenious mind to the devising of some kind of lamp which would not prove dangerous. Dr. Clanny of Sunderland had taken up the subject two years before, but had not yet surmounted the difficulties. In the month of August, Stephenson drew out a sketch for a lamp, which, after conferring with Mr. Nicholas Wood and other colliery engineers, was sent to a lamp-maker at Newcastle. The new lamp was ready on Oct. 21st, and was tried successfully on the same day. Stephenson then made a few improvements, and caused a new lamp to be ready by Nov. 4th. Again he experimented and made improvements, and a still more complete lamp was ready by Nov. 30th; and the "Geordy" lamp, as the miners familiarly called it, at once came into use at Killingworth. During these very months Davy was at work on the experiments which led to his safety-lamp; and it is now clearly proved, by the evidence collected in Smiles's 'Life of George Stephenson,' that the illustrious chemist and the humble engine-wright arrived by wholly independent paths at a knowledge of the facts concerning the passage (or rather the non-passage) of flame through tubes and small apertures. The coal-miners of the north did justice to Stephenson in a very public way in 1817.

The merits and defects of safety-lamps have formed a subject for many committees of inquiry. The parliamentary committee of 1835 has already been adverted to. A great explosion near Sunderland in 1839 led to the formation of a South Shields committee, the members of which devoted three years to the collecting of evidence relating to the causes of colliery explosions; and one of the results to which they arrived was, that the safety-lamp might in some circumstances be a source of danger rather than security, if it induced a neglect of measures for ventilating the mines. There was a committee of the House of Lords appointed in 1849 to inquire into the causes of these terrible disasters; this was followed by similar committees of the House of Commons in 1852 and the next two years; and the result of all the inquiries was to show that any one among a large variety of safety-lamps would render useful service, provided care be taken in the using. It is, however, painfully evident that this amount of care is not always taken; for the miners are too often thoughtless in the use of their lamps.

In briefly noticing some among the many kinds of safety-lamp devised since the time of Davy, it may be useful to mention that they depend for their safety on two principles—the obstructive action of wire-gauze, and the protective shield afforded by a glass cylinder. Of the Davy lamp enough has been said in former paragraphs; the method of arrangement has only been slightly altered since his day.

The Stephenson lamp has a glass cylinder inside the wire-gauze cylinder. The air is supplied through a triple circle of small holes in the metal bottom. Inside the top of the glass cylinder is a sort of metal chimney full of small holes. The lamp gives a steady light by being protected from the currents of the mine. It has a few advan-

tages over the Davy, but is generally considered by miners not quite equal in security to some others presently to be noticed. If the glass cylinder breaks, the lamp becomes a common wire-gauze lamp, but with rather too large a diameter; for it is found that if the diameter be more than about $1\frac{1}{2}$ inches, too great a volume of explosive gas might be contained within it.

The Smith lamp, a modification of the Stephenson, admits the air through the wire gauze as well as through the perforations in the metal plate; and there are other arrangements for preventing the stoppage of the perforations by dust and oil—an evil to which the Stephenson lamp is subject.

The Clanny lamp has an apparatus for extinguishing the flame in an explosive mixture, when the flame is of sufficient strength to extend itself high in the lamp. The flame melts a thin wire, which lets fall a shield or extinguisher, so placed as to put out the gas-flame, leaving a very small oil-flame sufficient to light the miner away from the dangerous place. Dr. Clanny has devoted a large amount of attention to the minor details of the lamp, especially to the mode of admitting air for combustion.

The Upton and Roberts lamp has a glass cylinder *outside* the wire-gauze cylinder. The air is admitted through horizontal apertures just over the oil-vessel, and then has to follow an intricate route before it can touch the wick. As a warning of the presence of foul air in the mine, it is the most sensitive of all the safety-lamps; but this sensitiveness is the very cause of the lamp not being much used, for its light is either dimmed or actually put out by causes very likely to occur in a coal-pit; and the miners hence dislike it, although it is spoken very highly of by scientific men, who test it in their laboratories.

The Martin lamp has no wire-gauze. The air is admitted through perforations in a metal bottom to the wick. The body of the lamp is a glass chimney, on the top of which is a copper chimney contracting gradually to a cone. It is very delicate in its action, extinguishing itself almost on the approach of carburetted hydrogen. This would, however, render it useless in a very fiery mine; besides which, an unprotected glass cylinder, without wire-gauze inside or out, is considered dangerous.

The Ayre lamp has an arrangement by which the air passes through a valve; the valve closes whenever the atmosphere becomes light or filled with foul gas, and thus extinguishes the lamp.

The Muessler lamp, much used in the Belgian coal-mines, is larger than the English lamps. A glass vessel surrounds the flame. The air can only reach the flame over the top of the glass, which is covered with wire-gauze. Over the glass, and as a continuation of it, is a wire-gauze cylinder, having a brass top full of minute holes. A small metal chimney pierces the horizontal disc of gauze which covers the glass, to give an outlet for the flame and the products of combustion. The air must pass downwards through this lamp before it can reach the wick. The Muessler lamp gives a good light, and is very safe against explosive mixtures; but it is heavier than the English lamps, and its unprotected glass vessel is liable to fracture; moreover, if held a little sloping (which is very likely to occur in use), the flame goes out.

The Lemielle lamp, also used in Belgium, is a sort of Davy lamp, with a glass cylinder fitting tightly inside it, and extending about half the height. The wire-gauze is spread out at the bottom into a treble-thick flat rim; and the arrangement is such that the air to feed the flame must pass down through the treble gauze rim into a space between the top of the oil-vessel and the wick, and then up again to the wick in the narrow glass cylinder.

The Whitehead lamp consists of an iron cylinder, with on one side a bull's-eye surrounded by reflecting surfaces. The air to support combustion passes through a number of small orifices round the oil receptacle, and thence through wire-gauze. The air admitted is purposely small in quantity. Wire-gauze is also introduced at the top of the chimney, so as to complete the isolation of the flame.

There are many other forms of safety-lamp which have engaged the attention of practical men,—such as Elsin's, a Belgian lamp intended to give more light than is usually obtained; Fyfe's, something like Clanny's, but having double gauze at the top instead of single; Watson's, which has apparatus for locking up the lamp in such a way that the miner cannot open it until it needs to be trimmed; Henderson's, with a double glass cylinder, having water between to cool the outer glass; Boty's, a Belgian lamp with gauze and glass; Martyn Roberts's, having a contrivance for extinguishing the flame if the lamp should be broken; Glover's, having two concentric glasses, and an arrangement for making a current of cool air circulate between them. Some have been made with the wire-gauze electro-silvered, in order to reflect more light; seeing that it has been found by Mr. Goldsworthy Gurney, that when dull iron wire is used, three-fourths of the light is lost.

Amid much diversity of opinion concerning the relative merits of these various kinds of safety-lamp, there is a pretty general agreement that the gauze cylinder should be accompanied by one of glass, to resist the action of strong currents of air; and that the glass without the gauze is not sufficiently protected against fracture.

LAMPIC ACID. Another name for *Aldehydic acid*. [ALDEHYDIC ACID].

LAND, in its most restricted legal signification, is confined to arable ground. In this sense the term is used in formal pleadings.

By the statute of Wills (1 Viet. c. 26), a devise of the land of the testator is to be construed to include customary, copyhold, and leasehold estates to which the description will extend, as well as freehold estates, unless a contrary intention appear. In its more wide legal signification land extends also to meadow, pasture, woods, moors, waters, &c.; but in this wider sense the word generally used is lands: the term land or lands is taken in this larger sense in conveyances and contracts.

In conveying the land, houses and other buildings erected thereon, as well as mines, &c., under it, will pass with it, unless specially excepted. A grant of the vesture of certain land is more restricted, and transfers merely a particular or limited right in such land, and the houses, timber, trees, mines, and other real things, which are considered as part or parcel of the inheritance, are not conveyed, but only corn, grass, underwood, &c., the produce of the land. Other limited or particular rights, as fishing, cutting turf, &c., may be granted, which confer no interest in the land itself, or, as it is called, the realty, but only the benefit of such particular privileges. But a grant of the fruits and profits of the land conveys also the land itself. Absolute ownership of land carries with it the right to the possession downwards of the minerals, waters, &c., and also upwards, agreeably to the maxim, "*cujus est solum, ejus est usque ad cælum*."

Ownership of land is expressed in the English law by the term *real property*, in contradistinction to *personal property*, which consists in money, goods, and other moveables.

Land is legally considered as enclosed from neighbouring land, though it lie in the middle of an open field, and may therefore be called a *close*; and the owner may subdivide this ideal close into as many ideal parcels as he pleases, and may, in legal proceedings, describe each of these parcels, however minute, as his close. An illegal entry into the land of another is therefore called, in law, breaking and entering his close, and the remedy is by the action of trespass, "*Quare clausum fregit*."

Land derelict, or left dry by the sudden receding of the sea, or of the water of a navigable river, belongs to the king by his prerogative; but land formed by alluvion, that is, by gradual imperceptible receding of any water, or by a gradual deposit on the shore, accrues to the owner of the adjoining land.

The word *land* is, by the interpretation clause of many statutes, as well public as private, made to include every species of real property and every denomination of right and interest therein.

(*Doctor and Student*; *Co. Litt.*; *Comyn's Dig.*)

LAND TAX is a branch of the public revenue of England, which was first raised in its present form in 1692. It was contrary to the spirit of the feudal system that pecuniary assessments should be made upon land held by knight's service, the personal military services of the tenants being in this and in other countries considered as entitling them to exemption from tallage, or direct taxation. The first inroad upon this principle in England was the payment of escuage as a commutation for personal service. This was followed by pecuniary grants made by parliament in the form of subsidies upon the abolition of the military tenures by the Long Parliament, which was afterwards confirmed by the first parliament of Charles II.; the ground of exemption ceased, and land as well as personal estate was made the subject of assessment.

Until 1799 the land-tax was granted by parliament for only one year, and the acts under which it was levied were renewed annually; but in that year an act was passed rendering the tax perpetual, the object of this alteration being to facilitate the raising of money by means of its redemption. Under the conditions of this act the tax was offered for sale first to the owner of the land upon which it was chargeable, and if the purchase were declined by him then to any other person, in which latter case the purchaser was to receive the amount half-yearly from the receiver-general. The payments were in either case to be made not in money, but by the transfer of an equivalent amount of the national debt. The advantage stipulated on the part of the public was, that if redeemed by the owner of the land, the interest or annuity transferred in payment should exceed the annual amount of the tax redeemed by 10 per cent.; and if purchased by an indifferent party, that the interest or annuity should exceed that annual amount by 20 per cent.: for example, if the land-tax to be redeemed by the owner amounted to 5*l.* per annum, the sum of 3 per cent. stock to be paid for the same would be 183*l.* 6*s.* 8*d.*, the annuity in respect of which would be 5*l.* 10*s.*, or 10 per cent. advance upon the tax. If the purchaser were a stranger, the amount of 3 per cent. stock would be 200*l.*, or an annuity of 6*l.* per annum, being 20 per cent. advance. This measure met with only a partial success, which occasioned several modifications to be made in its terms with the view of rendering them more acceptable to the landowners. The most important of these modifications were passed in 1811 and 1812, when the management was transferred from special commissioners to the Commissioners for the Affairs of Taxes; the preference given in previous acts to the owners was revoked, except as regarded priority where competition appeared, and the purchase-money was made payable by thirty-two half-yearly instalments.

The rate at which this tax is charged is 4*s.* in the pound on the

annual value, as rated at the time of imposition. Consequently the produce varies but little, ranging between 1,100,000*l.* and 1,200,000*l.* For the year ending March 31, 1859, it was 1,100,081*l.* for England, Wales, and Scotland. Ireland is exempt.

LANDGRAVE. In the early history of Germany the *Grave* was an inferior judge, who was chosen by the people for his experience in business. Under the Franks the *Graves* were no longer chosen by the people, but appointed by the kings or emperors, and were judges of a province; above them in rank were the *Herzogs*, or dukes; and below them the *Gaugrafs*, or judges of a district (called a *Gau*); a division of which there are still some traces in Germany, as the *Rheingau* and the *Vinschgau*, in which they exercised the rights of government in the king's name, having especially the administration of justice, the police, and the royal revenues. After the time of the *Carlovingian* kings the following classes were distinguished: *Palgraves* (*Pfalzgraf*, from *pfalz*, court), who sat in judgment at the king's court, and examined whether a suit must be decided by the king himself; *Margraves* (properly *Markgraves*, *Markgraf*), from *mark*, a frontier or boundary, who were keepers of the frontiers (lords of the marches); and *Landgraves*. Nearly all these titularies, however, soon made themselves independent of the sovereign. The *Markgraves* of *Thüringen* assumed the title of *Landgraves* towards the end of the 11th century, and it was obtained in the next century by the *Graves* of *Hesse*, in whose dominions the title is still borne by the *Landgraf* of *Hesse Homburg*, while the two elder branches have assumed the titles—the senior that of *Elector of Hesse Cassel*, the second that of *Grand Duke of Hesse Darmstadt*.

LANDING-STAGE, a structure erected upon the banks of a river, quay, or dock, for the purpose of facilitating the discharge of goods, or the landing of passengers, from the vessels frequenting the particular port or locality under consideration. Landing-stages under these circumstances may either be fixed, as in the majority of docks, where they are provided with hand, steam, or hydraulic cranes, or with other machinery for facilitating the operations of unloading; or they may be floating, as in the various passenger stations upon the *Thames*, or upon the *Mersey*, *Frith of Forth*, &c. The variable conditions of the loads to be discharged, in the first case, and of the rise of tide, or of the variations of the surface lines in the second, introduce such countless modifications into the details of landing stages, that it becomes impossible to lay down any general rule with respect to them; it may suffice, therefore, to refer to the landing stages at *Liverpool*; at *Blackfriars Bridge*, *London*; at the *Albert Docks*, *Liverpool*, the *Regent's Canal Docks*, and the *Victoria Docks*, as illustrations of this class of structures in some of its more striking modifications. In passenger-landing stages there should be provision made for booking, and for checking the arrival of travellers; and in goods landing stages there should be ample means for weighing, measuring, sampling, or packing the goods; in both of them, the vessels to be unloaded should be able to lie out of the ordinary course of the ships frequenting the particular place, and be able to cast off easily into the open water when required. The *Brighton chain pier*, and the landing stage of a somewhat similar character erected by the late *Sir I. Brunel* at the island of *Bourbon*, may be referred to as amongst the most remarkable landing stages on exposed coasts.

LANDING-WAITER, an officer of the customs, whose duties consist in taking an accurate account of the number, weight, measure, or quality of the various descriptions of merchandise landed from foreign countries or colonial possessions. Landing-waiters likewise attend to the shipment of all goods in respect of which bounties or drawbacks are claimed. These officers are likewise called *searchers*.

LANDLORD AND TENANT. [TENANT AND LANDLORD.]

LANDSCAPE GARDENING. [GARDEN.]

LANGUAGE, taken in its most general sense, may be defined as the means by which the thoughts of one mind are conveyed to another mind; and it may be assumed, as a self-evident proposition, that the channel must be one or more of the senses. Of these the most available are of course the sight and hearing, but not to the exclusion of the others. Thus the sense of smell is turned to account when the blood-hound is employed to track a fugitive, but the materials at hand for action on the nostrils, the *copia narium*, must needs be limited, nor would any reference to this sense, or that of taste, have been made on the present occasion but that it is always desirable in an inquiry, to cast a look, however transient, over the whole field. While visible language is employed chiefly for the purpose of recording knowledge, there are cases where it is needed for immediate use. Thus, to take the case of the deaf man in the farce of '*Boots at the Swan*,' a series of inefficient attempts on the part of a traveller to procure refreshments by verbal orders, when followed by a few movements of the hands, as of cutting food in a plate and conveying it to the lips. The captain again on the bridge of a steamboat, amid the noise of passengers and weather, by previously concerted movements, conveys his orders either to the boy above the engine or to the sailor at the helm. In those sad, but happily rare, cases, where the channels of the eye and ear are both closed, time was when the unhappy sufferer was left to a life of worse than brutal torpidity; but by modern science the sense of touch alone has been made to supply in some measure the deficiency, as in the well-known case of *Laura Bridgman*. The language then of the eye and the ear need alone claim our attention. Some remarks on the comparative advantages of these two forms of language have already

been given in a previous article [ALPHABET]. It may be sufficient on this head to notice the not unimportant fact, that it may often be advantageous to call the visible in aid of the oral language. Thus a shrug of the shoulders, a stamping of the foot, and movement of the hand in various ways, often add much to the intelligibility of a speaker.

In an endeavour to find out the origin of oral language, an inquirer is met by difficulties—some imaginary, some real. That the task is no easy one is seen at once in the fact that historical aid can be of little value, inasmuch as, from the nature of the case, written language belongs to a much higher civilisation than that which was contented with the language of sounds. On the other hand, little weight need be given to the doctrine occasionally put forward, that the attempt in itself savours of impiety, especially when the invention is ascribed to man's own efforts under the stimulus of the wants which social life brings with it. The *Book of Genesis*, it is now admitted by our best informed divines, was not written to form a code of science; yet, taken in its most literal sense, the *Mosaic account*, instead of justifying the assertion of a living writer, that God gave man language, expressly ascribes the immediate invention to Adam. The most scrupulous theologian therefore, will have no reason to quarrel with the views about to be put forward. Others again treat the problem as one insoluble for us. "How this latent power evolved itself first," says the writer already alluded to, "how this spontaneous generation of language came to pass, is a mystery, and as a mystery all the deepest inquirers into the subject are content to leave it." Let us hope that an attempt to throw a wet blanket on the inquiry will not be successful. In all departments of knowledge, "the impossible" has again and again been accomplished, and the solution has usually been effected by the establishment of principles not more remarkable for power than for simplicity. We think it the more important to urge this law of simplicity, as marking all just explanations of natural phenomena, because a certain love of the mystical has induced some modern writers to shut their eyes to what is really most simple in the present inquiry. The same writer, who has many claims on public attention, while he admits that man has adorned and enriched his life with various arts and inventions, objects to the theory that in like manner he invented language. To the doctrine, that from rude and imperfect beginnings, the inarticulate cries by which he expressed his natural wants, the sounds by which he sought to imitate the impression of natural objects upon him, man by little and little arrived at that wondrous organ of thought and feeling which he now possesses, he opposes the objection that language would then be an *accident* of human nature, forgetting that it is one of those accidents which must have occurred, so that chance at once merges in certainty. Moreover, what valuable and permanent results may come out of mere accident, has been shown of late in the highly philosophical doctrine of "*Natural Selection*" in the animal and vegetable kingdoms.

It was long contended that the significance attached to sounds was altogether conventional. Thus the author of '*Hermes*' (314) says: "The meaning of language is derived from compact." No doubt this theory of arbitrary signs is in itself thoroughly intelligible. The signal-flags of a fleet, the oscillations of the needles in a telegraph office, owe their value entirely to a previous understanding; but the explanation is utterly without solidity for oral language, inasmuch as we cannot easily imagine a man possessed of sufficient authority to dictate such arbitrary laws, or able to make known his wishes. Add to this the consideration that the absence of all natural connection between the significant sound and the thing signified, would render it the more difficult both to acquire and to retain a language so constituted. The theory then that would found language on the assumption of a compact, may be left to share the fate of other similar theories, such as *Rousseau's 'Contrat Social'*. On the other hand it is now all but universally admitted that some portion of language at any rate, owes its origin to an imitation of the sounds that occur in nature. The *moo-cow*, the *baa-lamb* of the child, the *cuckoo*, the *peewit*, the *whip-poor-will*, the *tuco-tuco*, are simple but irresistible examples of this law; and we have the same principle presented in the dialogue over the Chinese banquet, when, as the tale goes, an English visitor endeavoured to extract from the native waiter a little information as to the dish he was eating by the inquiring words "quack quack, eh?" and received the more intelligible than welcome answer of "bow-wow!" But if the imitation of actual sounds admittedly supplied one part of language, is it an overbold supposition that all language came from this source? Not that it is to be expected that in each individual case we should succeed in tracing up the meaning of a word to its onomatopoeic progenitor, for words are incessantly modifying their meaning, and the principle of association by which this result is effected, is often difficult to follow. No better proof of this difficulty is to be found than in the fact that the same word has occasionally obtained meanings diametrically opposed to each other. Thus the Latin noun *species*, lit. 'sight,' is at one time employed to denote what a person seems to himself to see, and thus we have a class of meanings denoting what is utterly unreal, just as our language owes to the same stock its nouns *specious* and *spectre*. At other times it has meanings in keeping with the doctrine that "seeing is believing," and it is in this way that we have in use the terms *specie*, "solid bullion," as opposed to paper money, and *spice*, which at one time vied with gold itself in value.

So the learned Dean of Westminster points out that *impatience* has borne at different times the opposite meanings of "impatience" (non-enduring) and "apathy" (non-feeling).

But to return to the subject of the formation of words on the principle of natural imitation, it is important to notice that there are those who would draw a line, by which words so formed are separated from the large residue of language. Thus there was published a few years back, a valuable paper by Buschmann, in the 'Transactions of the Berlin Academy,' in which he traces through the languages of the world the terms for the leading relations of family, as *father* and *mother*, and so establishes a remarkable similarity of forms over the whole surface of our globe. Another German writer in the 'Transactions of the Philological Society' (1859, pp. 34-36), has done the same for the pronouns of the first and second person. It matters little for the present purpose that the two writers, here spoken of, refuse to see in this identity of results a proof of the historical unity of mankind, contending that it can only prove the ideal unity of human nature; meaning it is supposed thereby, that different races of men may owe their possession of these words in common, not to tradition, but to the working of similarly constituted minds under similar circumstances. For our present inquiry it is enough that they fully admit the development of these words on natural principles, as opposed to any arbitrary law of dictation.

But if the view which ascribes the origin of words to onomatopœia be universally true, it will follow that the first development of language was the formation of active verbs, inasmuch as it is by action alone that noise can be produced. This proposition is in no way opposed to the commencing observations that the *moo-cow* and *bow-wow* owe their names to this principle; for the words *moo* and *bow-wow* denote first the act of lowing and barking, and then give a name for the beings that low and bark. Moreover, by the term active verbs are here meant not merely transitive verbs, as *strike*, but equally the intransitive, as *walk*, *run*, to the exclusion of all verbs denoting a mere state, whether of body or mind. This doctrine, which assigns a sort of primogeniture to the verb, receives no little support from the Arabic, which expresses the grammatical idea of a verb by a word strictly denoting action. (De Sacy's 'Grammar,' § 245.) Similarly the Chinese (Endlicher's 'Grammar,' § 219) denotes the same idea by *sing-tsé*, "living words," or *hō-tsé*, "words of motion;" whereas for nouns the terms in use are *ssè-tsé*, "dead words," or *tsing-tsé*, "quiescent words." Precisely in agreement with this, the terms *verbum* of the Latin, and *ῥημα* of the Greek, being limited to the verb, although etymologically they signify merely that which is spoken, imply thereby a marked supremacy for this part of speech. Nor is there much force in the argument of an able writer in the 'Proceedings of the Philological Society' (3, p. 163), that in many languages the same word is used alike for a verb and an abstract substantive of kindred power; as in Coptic, *ti* signifies indifferently "give" or "giving," so that with a pronominal affix there occurs *ti-k*, "giving of me," and with the further addition of a noun we have *giving of me this*, in the sense of *I give this*. When the writer in question gives to such a form as *ti* the title "nomen actionis," he really concedes all that is asked, for there cannot be found a better definition of a verb as here used.

Not a little support for the doctrine now maintained exists in the fact that the moment the idea of feeling is to be represented, the older forms of language exhibit an antipathy to the simple personal verb. Thus the Latin language abounds in such forms, as *pudet me ejus*, *tædet*, *pœnitet*, &c.; as also in reflective verbs, such as *reminiscor*, *obliscor*, *vereor*, *misereor*. Other languages exhibit a similar peculiarity: as the Greek, in *δὲι*, *ἐλπομαι*, *οἶτομαι*; the German, in *es gereuet mich*, "I repent;" *es friert mich*, "I am chilled;" *es ahnet mir*, "my mind forebodes;" *es ekelt mir*, "I loath;" *es träumt mir*, "I dream;" while in our own tongue we have still *methinks*; and the older language had *me-seems*, *it likes me*. Thus we have in Shakspeare the phrases: "An't like your grace" ('Measure for Measure,' v. 1); "His countenance likes me not" ('King Lear,' i. 1); "I'll do it, but it dislikes me" ('Othello,' ii. 3). Similarly, our verbs *fear*, *remember*, and *repent*, to take them as specimens, had the active sense before they were employed as verbs denoting a state of mind; or perhaps it would be more accurate to say, before they were used as reflectives. Thus, still to quote from our great poet: "Tush, tush, fear boys with bugs" ('Taming of the Shrew,' i. 2); "Her wits, I fear me, are not firm" ('Measure for Measure,' v. 1); "How I may be censured, something fears me to think of" ('King Lear,' iii. 5). Again: "Thou but remember'st me of mine own conception" ('King Lear,' i. 4); "And now I am remembered, scorned at me" ('As You Like it,' iii. 5). So, also: "I do repent me that I put it to you" ('Othello,' iii. 3); "I can again thy former light restore, should I repent me." And in the Bible: "It repented the Lord that He had made man" (Gen., vi. 6). Another proof that the verb of action belongs to the earliest state of language is found in the brevity of form which characterises this class of words. Thus the Latin so-called third conjugation consists chiefly of verbs which denote the simplest acts; and the special character of this conjugation is brevity, the roots consisting largely of a vowel flanked by single consonants; and if the other conjugations possess a few monosyllabic verbs, these also stand out from among their neighbours, as having a similar form of meaning. But, of course, in speaking of such verbs, we discard from view those suffixes which denote the persons, and further reject those

modifications, whether of a lengthened vowel or doubled consonant, which are commonly employed solely for the purpose of denoting an imperfect, or rather continued, character of action, by compelling the voice to dwell longer on the sound. Thus, to take our examples from the Latin, we have the verbs, *dūc*, "lead;" *dīc*, "say," or rather "show;" *fac*, "do;" *cad*, "fall;" *ser*, "sow," or rather "put;" *vel*, "pull;" *mit*, "let go;" *da*, "give," or rather "put;" *i*, "go;" *su*, "sow." The other conjugations have their chief employment in denoting either a state or a succession of acts, as *ama*, *frica*, *vide*, *alge*, *dormi*, *audi*, *volu*, *metu*: or, to mark the contrast better, we may point to such pairs of words as *iac*, "throw;" *iace*, "lie;" *sēd* (*sed-ēre*), "take a seat;" *sēde*, "be seated, sit;" *cap*, "take;" *habe*, "have;" *ten* (*tend-ere*), "stretch;" *tene*, "hold tightly, grasp."

The one main argument which may be opposed to the views here put forward is the doctrine, favoured by many grammarians, that all sentences ought to be reduced to the logical form, consisting of a subject, predicate, and copula. That this view of language is all-important for the syllogism, and consequently for argument, is admitted. It is not admitted that the first object in the formation of language was argument. An earlier and more important object was to enunciate facts and to give commands. In truth, the process by which a logician forces (for it is often sheer force) every sentence into his favourite form, so as to exhibit the so-called substantive verb, is altogether artificial; and not a little harm has been done to grammar by regarding language solely from the logician's point of view. Thus we find De Sacy, in his 'Grammaire Arabe' (tome i., § 246), expressing himself thus:—

Le seul verbe, qu'on puisse regarder comme absolument nécessaire à l'expression des jugemens de notre esprit, c'est celui qu'on nomme *verbe substantif* ou *abstrait* tel que *esse* in Latin, *être* en François. Celui-là seul ne renferme précisément que ce qui constitue essentiellement la valeur du verbe, l'idée de l'existence du sujet avec relation à un attribut.

Now there is not an idea more difficult of distinct comprehension and definition, even to the most highly educated, than that which is denoted by the term *existence*. In truth the verb *to be* may well be called *le verbe abstrait* by De Sacy; but an abstract term, however essential to a system of metaphysics, is among the very last that is called for under the wants of uncivilised society. The savage has his various terms for the several concrete forms of existence, but has no occasion for a general term; and in fact those who attempt to translate the language of a nation far advanced in civilisation into the language of a rude tribe, find an insuperable difficulty in words of this class. But on this point we may be satisfied with the evidence of one, whose extensive acquaintance with the most outlying language made him the best of witnesses, especially as his feelings were directly opposed to the doctrine of the verb here advanced, so that he could not be suspected of any too favourable bias. In vol. iv., p. 70, of the Proceedings of the Philological Society, Mr. Garnett writes:—"We may venture to affirm that there is not such a thing as a true verb-substantive in any one member of the great Polynesian family." Again, in p. 236, he expresses his belief that "a verb-substantive, such as is commonly conceived, vivifying all connected speech, and binding together the terms of every logical composition, is much upon a footing with the phlogiston of the chemists of the last generation." De Sacy also, though he lays down the doctrine that the verb *to be* is the only essential verb, was aware that in many languages the connection of the subject and predicate was denoted without the interposition of any verb; and, indeed, that in the Arabic itself a verb was no way essential for the purpose. In our own family of languages it is the fashion to give a sort of precedence to the Sanscrit as the most perfect specimen; and here again the expression of a logical proposition altogether dispenses with a copula. Now, when we put together the several considerations that the logical form of language is not that which adapts itself to the wants of early society; that the substantive verb so-called is not even requisite for the expression of logical ideas; that the idea of *being* in the abstract is beyond the comprehension of a savage; and that in point of fact a large number of existing languages do not possess such a verb, surely it is highly unphilosophical to construct a theory of language on such a basis. But there still remains a difficulty to be disentangled. It has been truly laid down that the most irregular verbs of a language are the oldest; and it may be safely affirmed that of all verbs the most irregular is that which signifies "to be," as is seen in *be*, *is*, *was*, of our tongue, *esse*, *sum*, *fui*, of Latin. The solution of the difficulty is found in the fact that *esse* had for its oldest meaning "to eat," and not "to be." The idea of eating is of course ever before the mind of the savage, simply because the fear of starvation is too constant a condition of his life, and may well claim an early place in his vocabulary. Nor is it difficult to see how from "to eat" comes the idea of "to live," or to deduce from the latter notion that of existence in general. Thus the authoress of 'A Residence at Sierra Leone' in Murray's Colonial Library, found the natives wholly unable to follow the use of our substantive verb, and was compelled at last to substitute *live* for *be*, before she could make herself intelligible. "Go fetch big tea-cup, he *live* in pantry," was the kind of language she found it necessary to employ; and the servant in announcing dinner would say:—"Dinner *live* on table."

To reject the logical view of early language involves, of course, the

rejection of the usual definition of the nominative, as the subject of the proposition. If the original verbs were limited to those which express action, a necessary consequence would be, that the nominative denotes the agent. This consequence may be readily admitted, and the more so, as it meets what seems to be a grave difficulty. A linguistic paper by Carl Bock, published in 12mo. at Berlin, in the year 1845, under the title 'Analysis Verbi,' drew attention to the fact, that in some languages the personal suffixes exhibited the form of genitives; and Mr. Garnett's paper, already quoted, produces other examples of the same apparent anomaly. But the moment that the idea of an agent or cause attaches itself to the term nominative, the difficulty vanishes, since the leading meaning of the genitive is the source "whence," as *calor solis* "the heat from the sun." And if it be objected to the theory, that the nominative is also used in connection with the passive, the simple answer is, that the passive was in origin a reflective, or, as our Greek grammarians prefer to say, a middle voice, so that the first translation of *servus occiditur* is "the slave kills himself;" and further it may be noticed, that when the Latin, using the passive, wishes to define the agent, it gives us *servus a domino occiditur*, which, compared with the equivalent phrase *dominus servum occidit*, teaches us that *dominus* in the one, and *a domino* in the other, express the same idea, the very point for which we are contending.

But if in one of the simplest sentences of the primeval language, the nominative denoted the agent or quarter "whence" the action proceeded, so, on the other hand, the accusative must have denoted the "whither;" and this result thoroughly accords with the habit of language. Thus Varro expressly defines the Latin accusative as answering to the question *quo*, "whither." It agrees too with the use of the accusative in such a phrase as *Romam eo*, "I am going to Rome," and with the Spanish practice of inserting the preposition *a*, "to," before the object of a sentence. And as it has been shown that the ideas of feeling required a wholly different construction from verbs of action, so here again the former class in the oldest varieties of language exhibit an antipathy to an accusative and indeed very generally demand a genitive to denote the object of the feeling, or as we should rather express it, the cause or source of the feeling. Thus arose such constructions as: *me tui pudet*, *memini virorum*, "*venit mihi Platonis in mentem*;" and if we go back to the earliest Latin, "*quæ non veretur viri*" (Afran.), "*fastidit mei*" (Plaut.), "*Justitiæ prius mirer belline laborum?*" (Virg.) And we find parallel examples in English, as it used to be spoken, as "Thou dislik'st of virtue." (Shakspeare, "All's Well that Ends Well," ii. 3.)

One decided example of a verb formed by imitation of natural sound must suffice in a short sketch such as the present. When a stone tied to a string is whirled violently round, or when we enter a room where machinery with its many wheels is in rapid movement, the ear catches very distinctly the sound which we may represent by *whirr*. Now *wir-en*, is the German "to twist," *vi-rer*, in French, "to turn;" while we apply the term *weir* to the turning of a ship, and *veer* to the turning of a weathercock. The same root is seen in the English secondary or derived words, *whirl*, *whorl*, *world*, *warp*, *worm*, *writhe*, *wreath*, *wrench*, *wrest*, *wrist*, *wring*, *wriggle*, *wrap*, *wry*. The Latin language exhibits the same base in *ver-t-ere*, "to turn," *ver-u*, "a spit," *vermis*, "a worm," *verminari*, which signifies indifferently "to breed worms" and "to writhe with pain," meanings which, however different in application, have in common the idea of turning. The adjective *varus*, "with crooked legs," and *varices*, "varicose veins" have the same origin. But the sound passes at times into a something which we may express by the softer and more musical *vel*, and then we have it in the sense of the Greek *ῥελ-ισσω*, *ῥελ-ις*, *ῥελ-ι-τροχος*, *ῥελω*, *ῥελυω*, the Latin *vol-v-ere*, *val-va*, *val-gus*, "with crooked legs," and as might easily be shown, if more room were at our disposal, *volgus* and *volgare*. In our own language we have *wheel*, *wall-ow*, *welter*, while the Germans have both the simple verb *wall-en*, "to roll," and the derived *wal-gen*, and *wal-z-en*. The list might be still further increased, if we called to mind that many words which now begin with *r* have lost a preceding *v*, as *rota*, *rotundus*, in Latin, equivalent to *vortu*, *vortundus*, and in English, *roll*, *ring*, sb. *ringlet*. The Latin *orbis* has also lost an initial *v*, just as the Danish *orm*, 'worm,' has lost a *v*.

Before passing from the question of original roots and their signification, it seems due to the name of the German scholar, Bopp, to record that in his view ('Vergleichende Grammatik,' § 105) the main principle of word-formation in the Indo-European class of languages consists in the union of verbal and pronominal roots, which, to borrow his image, represent as it were the body and soul of language. It does not appear that many philologists have followed him in this doctrine. But the unsoundness of it seems almost to force itself on the mind in the very term "pronominal." In fact pronouns are scarcely of a character to have been part of any language in its earliest stages, simply because they are, as their name tells us, but substitutes for other words; and assuredly a language might have attained to a very valuable consistency without the possession of a single pronominal word. Reasons will presently be given for referring a large majority of our third person pronouns to one single verb; and the pronouns of the first and second persons seem also entitled to claim a close connection with some of the numerals, of which more presently. In the meanwhile the readers of Bopp's great work may be asked to notice the tendency in that writer to refer the presence of an inconvenient vowel in word-formation to

the presence of some pronominal base—now *i*, now *a*, now *ya*, &c., without much consideration of any meaning the too convenient pronouns bring with them to the word in which he finds them.

From the question of monosyllabic roots the next step should be the principle of word formation or derivation; but a preliminary matter presents itself. There are those who would divide languages into genera, and claim for each a special formation. Thus we read of monosyllabic and polysyllabic languages, languages with triconsonantal roots, a synthetic or analytic method of formation, words formed by agglutination and others by internal change of the root syllable or syllables; and lastly, affixes are treated by this writer as having in themselves no signification, by another as expressing the additional idea which their addition carries to the root-syllable or simpler word. In all this there appears to be a very large proportion of error. A deeper examination of languages will perhaps always lead to a common result, that the roots were originally of one syllable, and that longer words are formed by the agglutination of such roots, with the understanding, however, that the affixed syllables, though in themselves originally roots, play commonly a less important part in the construction of the composite word. It may be useful to point to the causes which have given currency to the errors we have been speaking of. To begin with the Chinese language and others commonly classified with it, we are told that it is a monosyllabic language, "incapable of composition and consequently without organism, without grammar" (Bopp, V. G., s. 108, and A. W. v. Schlegel, *ibid.*). In other words we are taught to believe that it is altogether like those one-syllable stories which are considerably placed before the eyes of the child, when it takes its first lessons in reading. Unfortunately our knowledge of Chinese was first obtained through a medium which produced much distortion. The distance of the country and the opposition of Chinese authorities to all intercourse with foreigners, were serious obstacles to the attainment of accurate information. Many of our Chinese scholars made their studies of the language at Singapore instead of China; and of those who have had opportunities for a nearer view, too many have found, even at Macao, but very imperfect means of mingling with educated natives. Again, what we commonly call Chinese seems to stand to the languages generally spoken in that country, much as Latin did a few centuries ago to the vulgar tongue of Italy or France. In other words it is rather a dead than a living tongue. But there has been a still greater hindrance in the channel through which Chinese is studied. Our scholars have learnt it, as scholars always love to do, through books, rather than by oral communication. Thus, they have allowed themselves to be led astray by what is merely an accident of the written language. The characters being monosyllabic, they have hastily assumed the language to be the same; and thus Europeans commonly believe that the Chinese have been contented with a form of speech which, by its mere monotony, would have dispirited any other race of beings; while some have thought that this painful monotony may be, in native practice, partially corrected by the mysterious influence of the so-called four tones. Such views are upset by the simple testimony of one who had the best opportunities of obtaining exact knowledge, the late English consul at Ningpo, Mr. Robert Thom. From him we learn that the Chinese, like our own tongue, though rich in monosyllabic words, has no scarcity of disyllables and polysyllables. In the preface to his 'Chinese Speaker' (Part. 1, Ningpo, 1846,) he directs one who would learn the language to try to get an intelligent native of Pekin to read the Chinese and to follow him on the English side of the page (that is the side with the Chinese written in English characters, and having an interlinear English translation) "as a clerk follows the parson in church;" and he goes on to say, that such a student "cannot fail to observe, as he reads along, that many words are disyllables and not a few polysyllables; that some are accented on the ultimate, others on the penult, and others again on the antepenult, &c." Indeed Mr. Thom was prevented from marking the said accents solely by the paucity of accentuated letters at his command. A short example from his book may be of use:—

Yih-ko-jin	heō	Kwan-hwa lai	tso shim-mo-tī ne?
Now-a-man	in learning	the Mandarin language	what is his object?

Those who deny to the Chinese a grammar, seem to have started with wrong notions of what grammar is in their own language, and on that account alone have failed to find in Chinese that of which they were in search. The merest inspection of a Chinese grammar tells us that a certain syllable *tēi*, or in Mandarin more commonly *tī*, affixed to a substantive, serves to express the relation which Europeans denote by the term "genitive case," that another syllable, *tu* for example, added may imply plurality, and so on with the other secondary notions of grammar. Thus *uē-tēi sing*, "the origin of things," *Wen-vvang-tēi tē-tēi shun*, "the purity of the virtue of the Wen-vvang," or more literally, for the Chinese genitive always precedes, "the Wen-vvang's virtue's purity," *tē* denoting "virtue," and *shun*, "purity." So again, *gin* is "a man," *gin-tu*, "men." It is also true that at times the mere proximity of two words is sufficient to express a relation between them without the formal employment of a special particle. So with us, the nominative and accusative are sufficiently pointed out by their mere position, whereas in Greek and Latin, a suitable affix is required for the office. So again we say *moonlight*, when we mean the "moon's light." But it may by some be thought detrimental to what

is here said, that the syllables which the Chinese employ as affixes, have an original meaning of their own; for example, that the particle commonly used, as above said, to denote the genitival relation, is at times employed as a verb equivalent to the Latin *proficisci*, in other words, with the sense of "departure." But here we have only a proof that the Chinese grammar is less corrupted, purer, more simple, than our own; and we may further appeal to this instance in support of the doctrine, that all affixes were in origin themselves roots. It may also be noted that the omission of the genitival suffix, though common in ordinary Chinese, occurs most rarely ("fast niemals," says Endlicher) in the Mandarin dialect. In truth, the further we trace a language back, the more certain are we to find the suffixes expressed, as in *Πελοποννησος*, which is but a corruption of *Πελοπος-νησος*. Thus in the German *mond-en-licht*, the middle syllable may well be regarded as virtually a genitival suffix, a better theory surely than that which regards it as a euphonic insertion.

But while we would ascribe the false theory of the monosyllabic character of Chinese to the fact of our approaching the language through its syllabarium, so we have the converse error in the habit of attributing a specially polysyllabic or polysynthetic character to Basque and the languages of North America. Here there is, or rather was, no written language, and the traveller had no choice but to take down what a native spoke, as he spoke it, and of course with many of what we usually regard as separate words, all jumbled together in one confused mass. We need search for no better example than the polysyllabic term employed by the Aztecs in addressing a priest, as given under this word in the GEOGRAPHICAL DIVISION of this Cyclopædia. Shakspeare, and the inhabitants of Iceland, use for this purpose, the sufficiently short term, "Sir," but the Mexican layman addressed the priest as *notlazomahuizteopixcatlitzin*, which, being interpreted by Clavigero, amounted to: no, "my," *tlazonitli*, "esteemed," *mahuiztic*, "revered," *teo-pixqui*, "god-keeper," *tatli*, "father."

But the most formidable exception to this asserted law of monosyllabic roots is seen in the Semitic family, especially the Arabic and Hebrew, where it is maintained that all ultimate words are of two syllables, and contain three consonants. Nay, some continental scholars of the present day, carry their theory of Hebrew roots to the extreme point of denying it the possession of any vowel, so that *ktl*, according to them, is the root of the class of words signifying "kill." Such theorists seem to forget that spoken language has a priority over written language, for surely if they would picture to themselves the time when Hebrew was not yet written, they would find themselves in a "reductio ad absurdum," when declaring that to be a root which is confessedly unpronounceable. No doubt in Hebrew, as we now have it, the vowels are very variable, so that for example, we find *kôtel* denotes "killing," and *kâtal*, "killed." The Greeks too have such varieties as *νεμω*, *νομος*, *νομω*; but this has not induced our classical scholars to exhibit the root of this series of words as *νμ*. As to the variation of vowels within the limits of a root word, some remarks will presently be made; but to the doctrine that the roots of the Hebrew were originally disyllabic, we may oppose the strong belief of some of the ablest Hebrew scholars that this appearance is due solely to the fact, that secondary forms have supplanted the original simple stems. Similarly in our language *bellow*, *reckon*, *listen*, *begin*, *wallow*, have pretty well usurped the places of the obsolete verbs, *bell*, *reck*, *list*, *gin*, *wall*; and similarly in Latin, *sona-re*, *tona-re*, *lava-re*, *senti-re*, *cense-re*, *meti-ri*, might have passed for simple verbs, had not some of the older writers preserved for us such form as *son-ere*, *ton-imus*, *lav-ere*, while the existence at an early date of such verbal bases as *cen-* "puncture," "counting by prick of pin," *sen-* "feel," *men-* "measure," is established by derivatives, as *cen-sus*, sb., *cen-trum*, the Homeric *ε-κεν-σα*; by the perf. *sen-si*, *sen-sus*, sb., *sen-sim*, *sen-tis*, sb.; and by *mensus*, *mentor*, *mensura*, and *mēta* (that is, *men-ta*), "a mile-stone," so to say. But perhaps the most instructive example of disyllabic verbs simulating primary verbs, occurs in Hindostani, where the native grammarians lay it down as a general law that the simplest verbs, as in Hebrew, are disyllabic; yet the modern character of such a formation is at once established by the consideration that the great body of this language has descended from the Sanskrit, in which the monosyllabic form of primary verbs is undisputed.

The change of vowel in *kôtel* and *kâtal* belongs to a question which may be more conveniently considered presently, when the law of assimilated vowels comes under consideration.

But it is not uncommon for philologists to imagine to themselves a distinction between what they are pleased to call synthetical and analytical languages. Thus they would contrast the habit of some languages to express secondary ideas by affixes, as *patris*, *patrem*, *scribo*, *scribis*, *scribam*, *scripsi*, &c., with others, especially of modern date, which prefer to employ prepositions or formal pronouns in the nominative or auxiliary verbs; but it will be seen in the sequel that there is no substantial distinction between a case-ending and a preposition, that auxiliary verbs are employed in those affixes which belong to perfect tenses, and that the final letters of *scribo*, *scribis*, are as completely pronouns in origin as the *I* and *you* which an Englishman prefixes to his verb. The real distinction is, that in the one case the little words precede, in the others follow, unless indeed any stress be laid upon the corrupted form which often characterises affixes. Yet even here the distinction is not very marked, the letters *bi* in *ibi*, *alibi*,

nobis, *vobis*, being as fully pronounced as our own *by*, the *o* of *scribo* scarcely more abbreviated than our own *I*, while *I'm afraid*, *I've done*, *I'll tell him*, *I'd like to know*, have cut down the verbs *am*, *have*, *will*, *would*, as far as possible short of annihilation. But take such a case of contrast as *he did love* compared with *he loved*. When we trace the latter form upward, we find in the Anglo-Saxon *he lovede*; and if we ascend a step higher in the history of our language, so as to enter the domain of the Gothic, the oldest specimen of the German family, we find good evidence that such a form as *loveded* existed, but of course with the regular personal endings, which belong to the Gothic preterite, attached. (Grimm's 'Gr.' i. 840.) Thus the contrast is reduced to *he love-ded* as opposed to *he did love*; in other words, we have but a different arrangement of the same elements.

In all cases, no doubt, were our means of inquiry equally abundant, we should be brought to the conclusion that the formation of derivatives is but the agglutination of significant syllables to significant syllables, or, in simpler language, of roots to roots. This assertion is founded on various considerations: first, the mere fact that in a large and rapidly increasing number of examples what were unintelligible affixes have received their due explanation; secondly, the *a priori* argument, already employed to show that roots obtained their significance not by arbitrary compact, but by natural association; and, thirdly, the consideration that as affixes are attached to the end of words, and also sustain for the time an inferior office, they are doubly liable to a careless—in other words, shortened—pronunciation. On ship-board, for example, time is often of the first moment. Thus, when the writer once heard the French steersman of a French boat give orders to a "mousse" for dropping the foresail, in the words "Down with her," unconsciously speaking English, his inquiry as to the use of these words was met by the remark that "Faites-le-descendre" would be too long. No wonder, then, that sounds such as *bosen* and *foxel* should be preferred to *boatswain* and *forecastle*. Again, our own word *wanton*, at first sight of sufficiently obscure formation, has been analysed as representing *wan-tow-en*, "ill brought-up," where *wan* is the prefix seen in the old English *wan-hope*, "mala spes," and still abundantly flourishing in the Dutch language; while *tow-en* is the old participle of the verb *tow*, the equivalent of the German *zieh-en* and Latin *duc-ere*; so that *wanton* is substantially the same as the German *ungezogen*, "uneducated, untrained." Our term *workhouse* is self-explained; but this word is beginning to obscure the second element when pronounced as *workhus*. Again, take our word *mum* or *ma'am*—who beforehand would have supposed that the final liquid in this word represented the Latin word *domina*, as is the fact: *mea domina*, *madonna*, *madame*, *ma'am*, *mum*, and in one of Dickens's novels, *mim*.

Here we have seen the second part of the word shorn of its fair proportions. The blow may however fall on the prefix. Thus, *ava*, of the Greek language, when used before verbs, was reduced in the Æolian and Doric dialects to *av* and *or*, and under special circumstances to a mere *a* or *o*. No wonder, then, that the Latin *a-gnosc-ere* exhibits the same prefix as a mere vowel, or that the A. S. *on-cnaw-an*, and Shakspearian *a-cknow* (part. *acknow*, 'Othello,' iii. 3), as well as our existing *a-cknow-ledge*, have taken similar liberties. A still more violent corruption of what might be proved to be the same pronoun is seen in our *e-lope*, which represents the German *ent-lauf-en*, Dutch *ont-loop-en*. Cases even occur where the original root is wholly absorbed in some derived form. Thus, as Bopp has noticed, the German *im*, corrupted from *in-de-m*, has preserved the preposition and the case-ending, but wholly lost that to which they were at first attached, the element *de* (our *the*). Another example of similar extreme violence has been seen in *I'd* for *I would*, the essential syllable *wol* of the verb having utterly disappeared. As compression, then, is a very common occurrence in language, it behoves an inquirer not hastily to assume the radical character of all monosyllabic verbs. If he find two consonants either commencing or terminating the syllable, the strong probability is that a really disyllabic word is before him. Thus, *know*, *pluck* (*ck* is but one consonant), *culm*, *hulk*, should be regarded as corruptions of some such form as *ken-ow* or *con-ow*, *pul-uck*, *cul-um*, *hul-uck* or *hul-ock*, and so only secondary formations from the simple *ken* or *con*, *pull*, *coal*, *hull*. Nay, in many cases where the initial consonant is a simple *r*, *l*, or *n*, a truncation of the commencing letters may be suspected. For example, the Latin *nosc-ere* is historically known to be a corruption of *gnosc-ere*, where the first syllable represents our *know*, and thus *gen* or *gon*, corresponding to our *ken* or *con*, is the base. The related Greek *ονομα* has preserved the radical vowel, and only lost the guttural. So, again, when our *laugh* (Germ. *lach-eln*) is placed beside the Greek *γελα-ειν*, *γελακ-σω* (*γελαζω*, Doric fut.), we see that the base of the words is *gel*. For an example of a deceitful *r*, we may quote our verb *run*, which in the Dorset dialect is *hirn*, and here the *n* is but the remnant of a common suffix, as seen in *op-en*, *heark-en*, *burn*, *mourn*, *turn*. The base, then, is *hir*, corresponding to the Latin *cur* of *curro*, the interchange of *h* and *c* being the law between these languages.

In the formation of secondary words, by such agglutinations as we have spoken of, due attention must be paid to those very natural laws which require an adaptation of discordant elements, a subject treated in all its integrity in Sanskrit grammars, under the title *Sandhi*, "composition." The main principles are the same for all languages. Thus, when medial or thick consonants, so to say, are brought into contact

with thin consonants, the one or other must change its character. For example, in Greek you may prefer the thin consonant and say *ἐπτα*, *οκτω*, or you may prefer the thick and say *εβδομος*, *ογδοος*; but adaptation, at any rate for the voice, is required. So again labials and dentals refuse to coalesce. A German says *lende*, 'loins,' a Roman said *lumbi*; in Greek we have *αυα-δευ-ειν*, or for an Æolian *αυ-δευ-ειν*, "to wet for the first time;" in Latin *im-bu-ere* is preferred. But the most important, yet most neglected, law of assimilation in the composition of words, is that which concerns the vowels. No doubt the Sanscrit grammarian dwells at sufficient length, on the effect produced by the contact of two vowels, as when he tells us that the meeting of a final *a* with an initial *i* leads to the substitution of the intermediate vowel *e*, and similarly that the junction of *a* with *u* produces the intermediate vowel *o*. But a far more material point is the adaptation of vowels, more or less, when they are separated by consonants. In all dealings with vowels, whether in this Sanscrit habit of combining *a* and *i* into *e*, or *a* and *u* into *o*, or in the larger question now opened, the main guide of the philologist is the vowel law, established by the experiments of Professor Willis, namely,—that the kind of vowel-sound produced by the vibration of a reed, depends solely on the length of the tube that intervenes between the reed and the point of opening into the outer air; and that, as the reed is lengthened, we have a succession of sounds in the same invariable order, *i*, *e*, *a*, *o*, *u*, as pronounced by an Italian, not that the sound jumps from one of them to the next, but passes by imperceptible degrees through other sounds intermediate between them, which our alphabet is utterly unequal to denote, and indeed no alphabet could in perfection. But for the full comprehension of the question, the paper, or rather two papers, should be read *in extenso*, as given in the Transactions of the Cambridge Philosophical Society for Nov. 24, 1828, and March 16, 1829. Now as the character of the vowel depends, for the human voice, solely on the distance between the *chordæ vocales* in the *larynx*, which act as the musical reed, and the margin of the lips, and is otherwise in no way dependent on the form taken by the organs of speech; and as on the other hand the character of the consonants depends solely on the form and relative position for the time of these organs, the length of the vocal tube being immaterial, it follows that it is an easier matter to produce the sound of a polysyllable, all the vowels of which are the same or similar; and in this, as in all the labours of man, the saving of trouble is a paramount consideration. Hence, in savage nations, the abundant supply of such geographical terms as *Mississippi*, *Tennessee*, *Alabama*, *Oronoco*, in America, or of *Kamchatka*, *Japan*, *Palawan*, *Sarawak*, *Sambawa*, *Samarang*, *Balambangan*, *Banca*, *Java*, *Malacca*, *Andaman*, *Madagascar*, *Loochoo*, *Siou-siou*, *Sooloo*, *Comoro*, &c., in Asia. Hence too in the formation of secondary words there is a constant tendency to assimilate the vowels of united syllables, when they happen to be discordant. This may be effected in several ways, by the adaptation of the first vowel to that which follows or the converse, or thirdly by an approach of one or both to some intermediate sound. It is commonly by a modification of the first syllable that the object is attained in the German, Scandinavian, and Celtic languages, and so far as the principle prevails in Greek and Latin, all of which are members of the great Indo-European family. On the other hand, in the languages of Tartary, Turkey, and Hungary, as well as those in northern Europe and Asia, spoken by the Finns, Lapps, &c., it is the suffixed syllable that is compelled to take a vowel more or less similar to the vowel of the preceding syllable. Hence, in languages of this class, for all that have been just enumerated belong to one family, we find suffixes to a great extent running in pairs, which, with a common power, have no other difference in form than the interchange of a strong and weak vowel. Thus, in Turkish, *kapak*, a cap, has nom. pl. *kapak-lar*: but *ev*, a house, has a nom. pl. *ev-ler*; and again the datives pl. of these nouns are respectively *kapak-lar-ah* and *ev-ler-eh*. Or, to take an example from the Hungarian, the verbs *vár*, "wait," and *ismer*, "know," form the following persons:—

varok, I wait.
várunk, we wait.
vártok, ye wait.
várnak, they wait.
váratok, ye waited.

ismerek, I know.
ismerünk, we know.
ismertek, ye know.
ismernek, they know.
ismerétek, ye knew.

Nay to such an extent is this law of assimilation carried out in the Mongolian, that it is turned to account in economising the number of alphabetical characters. As the first occurring vowel decides the character of those that follow, a common symbol is used in all syllables after the first for *a* and *e*, a second common symbol for *o* and *ö*.

But in the other division of languages, as was just said, it is the first syllable that adapts itself to those which follow. If we look to the German languages, the familiar modification called "umlaut" is for the most part made in the direction of exchanging strong for weaker vowels. Thus *a*, *o*, *u*, if followed by a syllable containing either *i* or *e*, are apt to become *ä*, *ö*, *ü* respectively, where the two dots represent, and indeed have grown out of, an *e*, and *ae*, *oe*, *ue*, severally denote sounds weaker than those which they displace. One of the most interesting cases of the *umlaut* to be found in German, is seen in the second and third persons of many so-called irregular verbs, as *schlaf-en* "to sleep," *du schläfst*, *er schläft*; *stoss-en*, "to push," *du stösst*, *er stösst*. But it may be asked why the same modification is not found

in the other persons, *ich schlafe*, *wir schlafen*, &c., and the answer is only to be found in the formation of the old German, where the suffixes of the several persons are: 1.—*u*, 2.—*is*, 3.—*it*; pl. 1.—*ames*; 2.—*at*, 3.—*ant*; so that the only persons which by the weak vowel of their suffixes were originally entitled to the influence, are precisely those for which it is claimed. But it is not merely the *a*, *o*, *u*, which are subject to the influence of the *umlaut*; to the same cause must be attributed the modification which occurs in the second and third persons of *brechen*, "to break," whence *du brichst*, *er bricht*; *essen*, "to eat," *du issest*, *er isst*; *geschehen*, "to happen," *es geschieht*.

But while the weakening of stronger vowels is the phenomenon so common in German, the Norse, over and above this, abounds in examples of the converse action. Thus *kalla*, "to call," has *köllum*, "we call," where *ö* has a sound more nearly akin to *u* than to *o* itself. Again, *drecka*, "to drink," has a past tense sing. *drack*, pl. *druckum*, while the subjunctive is *drycki*. Similarly *dör*, "a spear," has in the pl.: n. *derir*, ac. *deri*, dat. *dörum*, gen. *darra*. Nay the influence of the added suffix often extends over two syllables. Thus from the same verb, *kalla*, is deduced a past tense, which in the singular has for its first two syllables *kallað*; but taking a *u* in the three suffixes of the plural, presents us with *þer kölluðum*, *þer kölluðuð*, *þeir kölluðu*. Similarly among the adjectives, the form *hagast*, "most handy," *annar* (= Lat *alter*), have for the dat. pl. *högustum*, *öðrum*. Still more effective is the attraction in *ketil*, a "kettle," which has pl.: n. *katlar*, ac. *katla*, dat. *köllum*, gen. *katla*.

In the Celtic family the following examples of modified plurals are taken from the Breton: *baz* "stick," *bizier*; *taro*, "bull," *tirvi*; *falch*, "scythe," *filchier*; *mab*, "son," *mipien*; *dred*, "starling," *dridi*; *lestr*, "boat," *listri*; and even with the influence extending through two syllables: *kalvez*, "carpenter," *kilvizien*; *enez*, "island," *inizi*. In some of the examples the suffix of plurality, whether it was *en* or *er*, after effecting the modification of the previous vowel, is itself dropped; no doubt because the modification itself gave a sort of notice that the plural suffix was about to appear, and so by anticipation rendered that suffix superfluous, the consequence being that, what was thus useless, was dropped. Similarly we find *dant*, "tooth," pl. *dent*; *oan*, "lamb," *ein*; *dañvad*, "sheep," *deñved*; *abostol*, "apostle," *abestel*; *azrouand*, "devil," *ezrevend*; *escob*, "bishop," *esquebyen*, or *esqeb*. The Breton verb is even more instructive in respect of this law. Thus *gall-out*, "to be able" (*val-ere*), has for its future: 1. *gellinn* or *gillinn*; 2. *gelli* or *gilli*; 3. *galló* or *gelló*; pl. 1. *gellimp* or *gillimp*; 2. *gallot* or *gellot*; 3. *gelliñt* or *gilliñt*—where it may be observed that *gell* has to contend with a rival, *gill*, whenever the weak *i* follows, and with *gall* before a suffix containing a strong *o*. In the verb *lavar-out*, "to say," the assimilation runs through two syllables, as *lavarann*, "I say;" *levere*, "thou sayst;" *livirit*, "ye say." It should be added that when the vowel thus subjected to "umlaut" is *ou* (*u*, *oo*), a trace of the *oo* sound is preserved by the substitution of *we*. Thus from *gouzout*, "to know," comes a future, *gwez-inn*. In English the principle has a more extensive sway than is commonly supposed. A few examples are: *old*, *elder*; *good* (Germ. *gut*), *better* (for *gwetter*—cf. *gwezinn*, just dealt with); *cat*, *kitten*; *foal*, *filly*; *one*, *any*; *fox*, *vixen*; *shake*, *shiver*; *quake*, *quiver*; *pray*, *prythee*; *cock*, *chicken*; *Jane*, *Jenny*; *Kate*, *Kitty*. And not unfrequently the modification extends beyond what the written form denotes, as in *Greenwich*; *grass*, *grazier*; *one*, *any*; *brother*, *English*, *women*. In our plurals, such as *geese*, *feet*, *women*, we have what was just seen in the Breton, the modification of the root vowel (of *goose*, &c.) by the weak vowel of a plural suffix, and then the loss of that suffix.

We may occasionally trace the action of the same principle in the classical languages, as *νομο*-(n. *νομος*) and *νεμεσ*-(n. *νεμος*), from the verb *νεμειν*; *γονο*-(n. *γονος*) and *γενεσν*-(n. *γενος*), from *γε* of *γιγνειν*; *στροφ*- and *ναμ*-, as secondary verbs, from *στροφ*- and *νεμ*-, while in *οροφ*- beside the verb *ερεφ*-, we see two syllables subjected to the influence. For Latin we may quote *bene* beside *bonus*; *velim*, *vellem*, *velle* beside *volo*, *volam*, *volunt*; and in the conjugation of the verb *i*- "go" and the pronoun *i*- (n. *is*) the law holds that whenever the following vowel is *a*, *o*, or *u*, the *i* of the base gives way to the stronger vowel *e*, as *eam*, *eo*, *eunt* for the verb, *ea*, *eo*, *eum* for the pronoun. The instances now quoted are few, but must not be taken as in any way a fair measure of the extent to which the law of vocal assimilation holds in Greek and Latin. Other examples will follow, and more be hinted at.

The principles which have been enounced, of consonantal and vowel assimilation, together with the general doctrine that man endeavours to lessen the labour of speech by every species of curtailment and abbreviation, are not sufficient to explain the anomalies of word formation. We must further allow for the interchange of convertible letters, on which subject we may refer to the article ALPHABET, where the general relations of the letters to each other are considered, and to the separate articles on the individual letters. But it is scarcely more important to lay down true principles than to guard an inquirer against prevailing fallacies. No field more abounds in weeds of this character than the learned pages devoted to the subject of the so-called grammatical figures. To such of them as denote the loss of letters, whether initial, internal, or final, the only objection is, that they are often thought to carry with them an explanation, whereas their only use can be to serve as labels for a given class of changes. But all those pseudo-learned terms which are so freely used by philologists to account for

letters and syllables whose presence they cannot explain, are unqualified nuisances, the removal of which can only be beneficial to the science. Such are all those which assume the addition of letters or syllables which are confessedly of no meaning, and so only add to the labour of utterance, as *prosthesis*, *epenthesis*, and *paragoge*. They are habitually called in to explain the older and fuller forms of language, on the strange assumption that the later, and for that reason more common, and at the same time more corrupt, varieties are the genuine words. In truth, when a word occurs in two forms it may be assumed, *a priori*, that the fuller is the older, if only because the loss of letters is explained by man's general tendency to abridge his labours; while to the doctrine of added or inserted letters there is always opposed the difficulty of answering the question, why one letter rather than another was selected. This objection especially applies to those cases where a consonant is said to be inserted between two vowels for the sake of avoiding the disagreeable proximity of vowels, *hiatus vitandi causa*. There is also the standing objection in all such cases, why does the speaker add unnecessarily to his labour of speech? But these general arguments, grounded on theory, are constantly receiving fresh confirmation from the results of historical inquiry in particular cases. The phrases, "for the nonce," "the tone, the tother," are now explained by the fact that the pronoun *the* had older forms, *then* and *thet*, the final consonants of which have been unduly ascribed to the following word. It seems too not improbable, that the forms *nuncle*, *Nan*, *Ned*, &c., owe their first letter to a similar theft from the pronoun *mine*, as though *mine uncle* was erroneously divided into *my nuncle*. In the contest between the claims of *a newt* and *an eft*, it may be difficult to come to a just decision, but "epenthesis" is wholly out of the question. That *an* rather than *a* is the earlier form of our so-called article is now generally admitted, and equally so that the familiar *a* privative of the Greek language is but a corruption of an older *av*. Similarly, *εστιν*, *ετυψεν* (for *ετυψεν*), *λεγουσιν*, *λογουσι*, are the more genuine forms, which a careless pronunciation reduced to *εστι*, *ετυψε*, *λεγουσι*, *λογουσι*, and ultimately *λογοις*. But perhaps the most amusing instance of inverting the order of time is the explanation, still often met with, that the *archaic* infinitive of the Latin, such as *mirari*, is to be deduced from the *late* form *mirari* by the addition of a meaningless *er*. As regards the *t* which appears as an intruder in the French *ai-me-t-il*, a moment's thought will show that it is but the final letter of an older *aimet* for the Latin *amat*; and similarly, to quote a parallel case, though the *t* is silent in *il est vrai*, it assumes its full power in *est-il vrai*? But if these are matters now admitted, there still prevails the practice of treating many initial vowels as added for the sake of euphony. Thus the words *ονομα*, *ελαχυσ*, *ορυσσω*, *αρασσω*, when fully examined, will be found to have in the syllables *ον*, *ελ*, *ορ*, *αρ*, at any rate a portion, it may be the whole, of the radical element. In the case of *ονομα* it is demonstrable that an initial *γ* has been lost, the change being similar to that from *κανθραξ* to *ανθραξ*, *καπρος* to *απερ*, *κολαφος* to *αλαφα*. In *ορ-υσσ-ω* and *αρ-ασσ-ω* the syllables *υσσ* and *ασσ* are no more radical than in *αιθ-υσσ-ω* and *μαλ-ασσ-ω*; while the syllable *ελ*, in the sense of "little," is familiar in all the branches of the Indo-European family, and not the more to be despised because it commonly occupies the less important position of a suffix. Moreover it is a fact productive of suspicion, that the said euphonic vowel is usually claimed in cases where the next adjoining consonant is a liquid, especially one of the three, *r*, *l*, *n*, which, as above noticed, are constantly putting forward false claims to the initial place in a root. It will not, however, be at variance with the principles here expressed, if it be admitted that on the importation of a foreign word commencing with two consonants difficult of pronunciation, an initial vowel is naturally prefixed to aid pronunciation. In such cases as the French *nombre*, *comble*, *gendre*, *vendredi*, or the German *wochenlich*, the letters *b*, *d*, and *t* are no way insertions of foreign matter; they serve merely as notes that the preceding liquid must be pronounced with special distinctness to save them from absorption under the influence of the following *r* or *l*; for whenever we produce an *m* or *n* with unusual pressure of the organs, we have forthwith before us what is better denoted by *mb* and *nd*. It is on this principle that our own language has the words *hand*, *sound*, and in the vulgar tongue *gownd*, in place of the simple *n* of *manus*, *sonus*, and *gown*.

The use of the grammatical terms *tnesis* and *diaeresis* is also an act of anachronism. While it is the ordinary law of language to agglutinate independent words, and to crush adjoining vowels together, no doubt at times a poet may find it convenient to avail himself of earlier obsolete forms which were in use before such agglutination or crushing had taken place. But to treat *Ατρείδης* as deduced from *Ατρείδης* and call the process *diaeresis*, or to call it *tnesis*, when the old poet himself, before the agglutination of a preposition to a verb was yet effected, wrote *ἡμιν ἀπο λογιον ἀμυναι*, or when Herodotus under like circumstances, wrote *ἀπο μὲν ἐθανε ὁ στρατηγος*—this is simple perversity.

Again a large amount of unsound philology is concealed under the term *metathesis*. Although no doubt there occur instances where a letter shifts its position in a word either through error in the person who repeats it, or by a sort of involuntary stuttering, as, for example, in the French *frange*, Eng. *fringe*, from the Latin *fimbria*, as though it had been *frimbia*. The interchange of *sk* with *ks* is no doubt common in language, but here the real explanation is probably that for the ears

of many people the sounds *s*, or perhaps *sh*, and *k* or *g*, are so akin as to be readily interchangeable; and thus we have had in this island the names *frosc*, *frox*, *frosh*, and *frog*, all applied to the same reptile; and this interchange would naturally carry with it the interchange of *sp* and *ps* in those countries where a *k* is supplanted by a *p*. Similarly when a Spaniard substitutes *milagro* for the Latin *miraculo*, the substitution of *l* for *r*, which occurs in the first syllable, was for him a change of the faintest character, and this change once made encouraged the converse change in the third syllable. This however is no *metathesis*. As the erroneous doctrine here combated has established itself only too firmly among philologists, it is the more important to point out the cause which has led to the error. No doubt abundant instances can be found like *durch*, Germ., and our *through*, *θρασος* and *θαρσος*; *tero*, *trivi*. Here there is an apparent passage of the vowel from one side of the liquid to the other; but it is only apparent, the truth being that in all such cases the older form was possessed of both vowels. For the first pair of words just quoted, we still have the full form *thorough*; and the truth is that the word consists of two elements *thor*, "a door," and a diminutive suffix *ough*. *Θαρσος* and *θρασος* are to be explained as alike corruptions of a fuller *θαρ-ασ-ος*, in which *θαρ* represents the chief element, being the equivalent of our *dare*, according to the usual law that holds between the languages of a *θ* and *d* corresponding. The second syllable *ασ* is that so commonly found in secondary verbs of the Greek language, as *ταρ-ασσω*, *αρ-ασσω*. The case of *tero* beside *trivi* and *tritum* is explained by the Greek *τριβ-ω*, and better still by the Latin *ter-eb-ra*, where the base is *ter*, *eb* a suffix, seen also in *frem-eb-undus*, *gem-eb-undus*; which it is the less necessary to dwell on here as it will come under consideration again. What has tended to encourage the leap-frog doctrine here assailed, is the strange coincidence, as it may well appear, that the vowels should so generally be the same. The answer is to be found in the law above-mentioned, that in the composition of words there is ever a strong tendency to bring discordant vowels into harmony. Thus the Greek verbs *ταρ-ασσ-ω*, *ερ-εσσ-ω*, *ειλ-ισσ-ω*, *ορ-υσσ-ω*, have in truth a common suffix, which takes the several varieties of vowel to please the preceding syllable. Another interesting case of the same principle is seen in the series of words, all one in origin: *παλλακ-* "a young man," Lat. *pellec-* "a young woman," a euphuism for a concubine, Eng. *fillie* "a young mare;" *πωλο-* "a foal," Scotch *pollock* "a young fish or crab," *pullo-* (nom. *pullus*) "a foal" or "a chicken,"—where the first syllable seems to denote "young," and the suffix is of diminutival power, so that the words in themselves merely signify "a little young one."

The other figures, such as *aphæresis* "the cutting off the head of a word," *syncope* "the compression of the interior of a word," *apocope* "the cutting off the tail of a word," together with the terms *crasis*, *synaloephe* and *syneresis*, which deal with the compression of adjoining vowels, tell no untruth, and so may be left to the use of those who have an affection for hard words. The one general principle under which they fall, and this alone is of moment, is, that words are ever subject to diminution. No doubt false analogies may occasionally lead to a violation of this general principle. Thus our *island* and *sovereign*, as now written, have letters in them to which they are no way entitled, through a mistaken reference of them to the old French *isle* (*île*), and the word *reign* or *regnum*. A more justifiable form would have been *iland* (like the German *ei-land*), and *soveran* (Ital. *sovrano*).

To trace language through all its varieties of declination, conjugation, &c., would far exceed our fitting limits. Some two or three questions of leading moment can alone be considered, and we may justly give a precedence to the doctrine of diminutives on various grounds. They play an important part in the formation of verbs, substantives, and adjectives alike; once formed, they are apt to usurp the place of the primitive, and so cause the utter disappearance of that primitive; and by a natural consequence, when thus acting the part of primitives, they suggest occasion for the formation of new diminutives. Nay, this process is sometimes repeated again and again; and we may even venture to say that a large per-centage of language is made up of diminutival elements. As examples of diminutives wholly supplanting primitives we may quote the Italian *fratello* and *sorella*, the only terms in that language for brother and sister; the French *soleil* and *hameau*; the English *weas-el* (Scotch *ware*), *stocking* (Shakspeare *stock*, as "With a linen *stock* on one leg, and a kersey boot-hose on the other." "Taming of the Shrew," iii. 2), *wander*, and *learn*; the German *esel*, *ferkel*, and *schenkel*; the Latin *oculus* and *spargere*; the Greek *δακτυλος* and *κεφαλη*—in all which cases we must pass over into cognate languages, or search for obsolete forms, before we find evidence of the simple words from which they have been deduced. Another inconvenience arises from the variety of form which even the same suffix takes, a variety the less surprising, because the affix being often of no practical value is for that reason more carelessly pronounced. In our Indo-European stock the diminutival suffixes may perhaps be reduced to two original elements, *el*, and something like *ach* or *och*. But the *el*, as regards its consonant, easily slips into *er* on the one hand, *en* or *em* on the other; and by an easy change of the vowel the Latin employs *ul*, and *in* or *im*, rather than *el* or *en*; while the Greek seems often to give a preference to an *a*, as in *μεγαλη*, *μηχανη*, *κυαμος*. The element *agh* or *ach* is, however, the more fertile suffix, and its varieties are all but endless. In the Gaelic (and we purposely quote from one of the languages which have preserved more readily the guttural varieties

we find an abundance of forms, such as *curach*, "a wicker-boat," or "coracle;" *beach*, "a bee;" *camag*, "a curl;" while the English, especially if we include in our view Lowland Scotch, supply a list far exceeding the meagre limits of those quoted by Grimm. We have room only for *bittock*, *bullock*, *charlock*, *fistock*, *haddock*, *hassock*, *hillock*, *laverock*, *pellock* or *pollock*, *tussock*. The Scotch again gives us the clearest evidence of the tendency in this suffix to modify alike its consonant and vowel. Thus, the word *haddock* has in some localities given way to *haddow*, and elsewhere to both *haddick* and *haddie*; and the last of these suffixes, happening to have met with a general preference in the parts about Edinburgh, that is, in the domain of letters, has, as might have been expected, secured a great preponderance to such forms as *lassie*, *laddie*, or, as we now write them in the south, *lassy*, *laddy*. The Slavic and Gaelic itself may also be called, to show how readily a final guttural vanishes. Thus, *batach*, "a little boat," *pôcach*, "a little pocket," have *batach-an*, *pôcach-an*, in the plural, but only *bata*, *pôca*, in the singular. The old Slavic, again, has a number of words ending like *πραχ*, "dust," *μιεχ*, "leathern-bag," *κοχυχ*, "skin;" but in the later languages, Servian for example, the guttural has been rubbed off, and left us *πρα*, *μιε*, *κοχυ* (where we employ the Greek character as more readily intelligible to English readers); so also we ourselves have done well to prefer *way*, *hay*, *honey*, to *weg*, *tag*, *honig*, of the German. The classical languages have also the same suffix, as, for example, *ροδαξ*, "a dwarf rose," *λιθαξ*, "a small stone," *σπαλαξ*, "a mole," *παλλαξ*, "a youth," *ύραξ*, "a shrew-mouse" (over 60 might be given); in Latin, *limax*, but commonly with a variety of vowel, as *podex*, *silex*, *culex*, *pulex*, *cimex*, *apex*, *carex*, *sorex* (35); *radix*, *calix*, *salix*, *fili*, *fulix*, *larix*, *varix*, *struix* (25). In *ονυξ*, *cruix*, and *fruges*, the *u* has been preferred; and compression has destroyed all trace of the vowel in *arx*, *calc*, *falx*, *lanx*, *merx*, as it has also done in our own *lark* (*laverock*), *park* (Anglo Saxon *parruc*). The list is already tolerably large, but over and above the quotations just given from the third declension, we must also claim the great mass of the other or vowel declensions. We have already seen how a final guttural was lost in some northern languages, so in Latin, the adjectives *rosac-eus*, *violac-eus*, *testaceus* (24), compared with *lapid-eus*, tell us that *rosa*, *viola*, and *testa*, have suffered a similar curtailment; *aprug-nus* tells us the same for *apero* (nom. *aper*), *murtac-eus*, *hordeac-eus*, *sebac-eus* (21), *rapic-ius*, *tribunic-ius*, &c., for *murtus*, *hordeum*, *sebum*, *rapum*, *tribunus*. *Ensic-ulus*, *canic-ula*, *retic-ulum*, *genuc-ulum* (aft. *genic-ulum*), *metuc-ul-osus* (aft. *meticulosus*), *cornic-ulum*; *dicc-ula*, *rec-ula*, severally claim a final guttural for the nouns whose nominatives are *ensi-s*, *cani-s*, *rete*, *genu*, *metu-s*, *cornu*, *die-s*, *re-s*.

But as the aspirated guttural among ourselves has often passed into a labial, as witness, *laugh*, *rough*, *cough*, so we find our diminutive in *fluff*, and with loss of the vowel, *cal-f*, *hal-f*, *turf* (Scotch, *toor* or *ture*), *wharf* (Fr. *gare*), *wolf* (from *gul*, "yellow"); and a lip letter once let in, slips into other labials as *scall-op* (*shell*), and with loss of vowel *shar-p* (*shear*), *war-p*, *whet-p*. Again, *bloss-om*, *bes-om*, *bos-om*, *bottom*, and with loss of vowel, *fil-m* (*fell*), *cul-m* (*coal*), *qual-m* (Germ. *qual*). Nay, by a step further in advance, the *m* slips into an *n*, and so brings us to diminutives, which might well have been claimed for our preceding suffix *el* (corrupted to *en*), but that the historical examination decides against the claim. Thus the German *bus-en*, *bes-en*, *bod-en* have in the *n* a substitute for an *m*, which grew out of a final aspirated guttural; and the *m* of the Latin second declension of neuters has a like origin. Hence *apium*, *Ilium*, lead to *apiac-us*, *Iliac-us*. So again, a primeval *var-agh* may be assumed as the origin of our *brake*, "fern," and of the old German *var-am*, which has since passed into *farren* and *farn*, the last all but identical with our own *fern*; and this assumed *var-agh* stands well beside the Latin *fil-ic* (nom. *filix*). The assumption of a primeval *pod-agh*, in like manner would explain the existing forms *πυνδ-ακ*, *pod-ec*, *pot-am* (old Germ.), *boden*, and our own *bott-om*, as well as the Latin *fund-o* (nom. *fundus*). *W* is another form of the final consonant, as proved by *skrog*, *skruff*, *shrow*, or *shrew*, all existing varieties of what the Greeks called *ύραξ*, the Romans *sorex*.

But at times, a *t* also supplants the guttural of our suffix; but this change was probably brought about at first by special causes. When the base to which the suffix is added, already possessed a guttural, the pronunciation became not only unpleasant to the ear, but somewhat difficult to the producing organs. Under these circumstances, the guttural is apt to give way, at one time to a *p*, and at another to a *t*. We have already seen examples of the supplanting labial in *scall-op*. So the Greeks from *σκαλ* "dig," formed a name *σπαλ-ακ*, not *σκαλ-ακ*, or "the mole," and the Latin from a base *ac*, "sharp," and a secondary form *forc* (*furca*), gives us not *ac-ex*, but *ap-ex*, not *forc-ex*, but *forceps*, *forpex*, or *forfex*. In this way, what were once in actual use, as *emmock*, or *immet*, *gemlick*, *gabcock*, *mammock*, are now found only in the forms, *emmet*, *gimlet*, *gobbet*, *mammet*. We cannot then hesitate, even though the historical proof be wanting, to claim as deduced from a suffix *ock*, the words *spig-et*, *cl-et*, *crick-et*, *lock-et*, *pock-et* (*poke*, Shakspeare), *smick-et* (*smock*); and a suffix *et* once established, the condition of its origin is forgotten, and we have *eyot*, *blot*, *mallet*, *sillet*, *tippet*, *wart* (*verruca*), *silt*.

But as was above said, one diminutival suffix was not enough, and not only are they added one after the other, but often, at any rate in later days, two at a time. Thus from the verb *leum*, "leap," the Gael forms

leum-ach-an, or *leum-n-ach*, "a frog." The German *chen*, and our own *kin*, are justly regarded as corruptions of *ich-en* and *ik-in*, and therefore twofold in origin. Thus the German *männchen*, stands for *männ-ich-en*, our *mani-ki-n*. The Latin again has the very same double suffix in *ferul-agon-ole-agin-eus*, *im-agon-*, *vor-agon-*; and the Greek in *πολ-ιχν-η*. The suffix *ling* is in like manner made up of *el* and *ing* (the last being a variety of *an* or *en*), and *let*, of *el* and *et*; but in both cases, the two elements have coalesced so completely, that for the creation of a new diminutive, they must be bodily attached as one suffix. The word *πολ-ιχν-η*, just quoted, has, when strictly examined, no less than three suffixes of diminutival power; but even this is not enough to content the passion. A Scotchman will talk of "sic a bonnie, *litt-le wee bit lass-ick-ie*," where the notion is expressed eight times; and a German amasses five diminutival suffixes in a single word, when from the monosyllabic *ass* he deduces *es-el-in-ch-il-in*.

For adjectives we will briefly refer to *shall-ow* (*shoal*), *callow* (Germ. *kahl*), *fallow*, (Germ. *brach*), *sallow*, *yellow*; *black-ish*, *whit-ish*; to *liθ-αξ*, "stony," *μαίμαξ* "boisterous," *σκιναξ*, "nimble," *ἡδυσ*, *βραχυς*, &c.; to the Latin *ferax*, *edax* (40), and *trux*; to *molli-s*, *turpi-s* (beside *mollic-ulus*, *turpic-ulus*), to *laetus*, *tristis*, *justus*, *amicus* (beside the irregular yet fairly established comparatives, *laetic-ior*, *tristic-ior*, *justic-ior*, *amicit-ior*, and the undoubted nouns, *laetit-ia*, *tristit-ia*, *justit-ia*, *amicit-ia*).

In the case of a verb, as Dr. Johnson has noticed when speaking of our own *jingle*, *sprinkle*, the addition of a diminutival suffix implies "a frequency or iteration of small acts." This character belongs essentially to many verbs, as for example, to the ideas of "rubbing, digging, writing, talking." A suffix then of diminutival power will be well applied in such cases, and indeed generally to a continued state of things. It is this way that *αγ* or *αχ*, with its varieties plays such an important part in the Greek verbs, specimens of which have been already quoted, as *ταρ-ασσ-ω* (*ταραχ-η*) *ορ-υσσ-ω*, &c., in the Homeric iteratives in *εσκ-ον*, in the Latin so-called inceptives *repuer-asc-o*, *ard-esc-o*, as also, *lac-ess-o*, *expet-ess-o*, *incip-iss-o*; the Italian, *fin-isc-o*; French, *fin-iss-ant*, and our own *fin-ish*. Again, the suffix appears almost uncorrupted in *pl-ag-* (*plango*), in *trah-* (*traho*, *traxi*), in *pl-ec-* (*plecto*), *flec-* (*flecto*), *gnic-* (*nitior*), *frug-* (*fruor*, *fructus*, *fruges*), *strug-* (*struo*, *struxi*), *fl-ug-* (*fluo*, *fluxi*); and softened into a labial or semi-vowel *vol-v-o* (our *wallow*), *solv-o* (our *slack*), and with the consonant alone preserved in *spar-g-o*, *mer-g-o*, *ver-g-o*, *ter-g-o*.

But passing from these individual words to the secondary or vowel conjugations, the special use of which is to denote continued action, there is strong reason for the belief that the vowels which characterise these conjugations, are themselves but the remnants of the diminutival affix *agh*; and this is the reason why the first conjugation so thoroughly outnumbers the others. The derived nouns, *mirac-ulum*, *spirac-ulum*, *orac-ulum*, *ambula-cum*, *lavac-rum*, when compared with *jac-ulum*, tell us in plain terms that the verbs, *mira-*, *spira-*, *ora-*, *ambula-*, *lava-*, had once a final guttural; *vorag-o* and *solac-ium* (which is the true form, not *solatium*), say the same in behalf of verbs, *vor-agh*, *sol-agh*. The Greek Doric future *γελαξω*, as we have already said, gives the best evidence that *γελα-* stands for *γελα-ακ*, and so brings it into the closest connection with the German *lach-el-n*, and our own *laugh*. But the pronunciation of this English verb reminds us, that we have to look for a labial substitute in the classical language. The verb *γρ-αφ-ω*, as well as *scalpo* and *scribo*, all three related words, may be taken as examples. But it is in the first conjugation that the labial form most abundantly presents itself, as shown by the four classes of derivatives, which we represent by the examples: *a. voc-ab-ulum*, compared with *jac-ulum*; *b. contion-ab-undus* (over 60), compared with the participle *reg-undus*; *c. am-ab-ilis*, compared with *ut-ilis* (400), and the tense forms *am-ab-am*, *am-ab-o*, which are of course co-extensive with the conjugation itself. Thus in *am-ab-a-m* it is only the third *a* which, as in *er-a-m*, *ε-τιθε-α*, denotes past time, and the junction of the two suffixes makes up the idea of "past imperfect;" while in *am-ab-o*, which is without the suffix of past time, we have an imperfect present, and this in many languages is the ordinary form for a future; and the case occurs too in the Greek *ειμι* "I shall go," and the Lat. *er-o* "I shall be," neither of which have any special suffix of futurity. The Sanscrit *e-kar-av-am* "I was doing," from the root *kri* or *kar* "do," has in the two last syllables, what confirms the explanation of *am-ab-a-m*. What has been said is far from all that the subject suggests, but it is time to proceed to other matters.

The pronouns of the third person, whether demonstrative, relative, or interrogative, have in all languages an intimate connection with one another. That the so-called definite article had for its original power the idea of *this* is generally admitted. Then, as regards what appears at first sight to be a formidable difference, that between the ideas of "this" and "that," Bopp observes in his 'Grammar' (§ 371), "That which in Sanskrit signifies 'this' means also for the most part 'that,' the mind (he should rather have said the finger) supplying the place, whether near or remote." Exactly in the same way, it is only by repetition that the idea of another attaches itself to the Latin word *alius*. In form it represents the Sanskrit *anya*, and, except the last letter, is absolutely in form and origin identical with our own *any* (Germ. *ein-ig*), which is but a diminutive of *an* or *one* (Germ. *ein*). Thus, "aliud est maledicere, aliud accusare," receives its strictest interpretation in the words "it is *one* thing to abuse, *one* to accuse." Then,

again, the relative is habitually represented by words which are admittedly demonstrative in power and origin, as in our own phrase, "the man *that* I saw," or, still more simply, "the man I saw," where it is an error to suppose that any pronoun is understood. So in Greek, more especially for the Ionic dialect, it is often idle to draw a distinction between the article *τὸς* and the relative *ὃς*. Our old poets, too, use *there, thence*, with the meaning of *where, whence*. Conversely in Latin conjunctions, such as *postquam*, the literal translation of *quam*, in spite of its identity in form with the relative, is just the same as that of *dem* in *nachdem*,—namely, "this," referring to the words that follow. Precisely in the same way, *ut*, so closely connected with the Latin relative that it may be regarded as a shortened form of *quod*, corresponds for the most part in use with our own conjunction *that*.

A calm consideration of what is meant by a relative clause will perhaps clear this anomaly of all substantial difficulty. A sentence which involves a relative consists of two clauses; that which contains the relative is used solely for defining something, which is to be spoken of in the second clause; and it is this second clause alone which carries with it the news that the speaker wishes to convey. If the object to be defined be present, he may point to it, and no further definition is required. If otherwise, it is convenient to suppose it for the moment to exist in the form of anything at hand. Thus, the lawyers of Rome, in conveying a distant estate in land, took up any clod of earth, and treated it as the actual land then selling. Thus one might say, "This horse I bought yesterday,—this horse I will sell you for 20*l*." or in Latin, "Hunc (or quem, no matter which) equum heri emi, hunc tibi vendam." Then, again, identity for the most part in form of the relative and interrogative needs not a word in proof, and the identity in power is clear in the case of the indirect interrogative. Thus, "Dic quis fecit" (*fecerit* in old writers is not necessary), might be translated by "Show me the man who did it," saving that an *s* happens not to be used with the relative; but this *s* has nothing to do with the base of the word, and indeed may at times be omitted from the interrogative itself. To translate *dic* by "show," is simply to revert to the older meaning of the word; and between the two phrases *quis fecit*? and *dic quis fecit*, to give a precedence in time to the latter, is in accordance with the habit of language, which ever cuts down long phrases to shorter; and in this particular case the omission of *dic* was the more natural as it was the standing commencement of every question, and therefore wholly superfluous, if the manner of the speaker suggested that he was asking a question. At the dinner table, "A glass of wine?" is quite intelligible without any interrogative whatever.

As the meanings, then, run all into one another, the chief question remaining is as to identity of form. Now it will be found that an initial thin guttural is found in *qui* and *quis*, in the Greek *κῶν, κῶρεπος*, in our own old *quwhat, quwhere*. Then, again, for the demonstrative, we have in the Latin *cis, citra, citerior*, &c.; in the Greek *κεινος, or κῆνος*; in the Tuscan *quello, questo, colui, costì*; and in a question of this kind, the Tuscan stands on equal ground with the Latin, for we know that the language of Tuscany, even in the days of Roman supremacy, abounded in gutturals. As for the other consonants which are seen at the commencement of third person pronouns, all surprise at the change must fall away when we look to *πov* supplanting *κov* in Greek, *pitpit* supplanting *quicquid* in Latin, while the Latin *quis* is the analogue of the Greek *τις*, just as *que*, "and," is of *τε*, "and." And if an *s* is seen in the Latin *sic*, Eng. *so* and *such*, and the compound *whoso*, we have what is perfectly parallel in the Greek *σητες, σημερον*, for *τητες, τημερον*. Then, again, the mere aspirate of *δ, ῥ*, beside *το*, and of *δς, ῥ, δ*, of the Latin *hic*, &c., and our own *he, here, hence*, is just the letter which is constantly superseding, now an *s*, now a *k*. Or if the loss of the aspirate itself in *is, ea, id*, be pressed, we have only to call to mind that what is now written *it* by ourselves was formerly written *hit*, and is still *het* in Dutch. A guttural is of all letters most likely to be corrupted, and hence, if there be reason to suspect that the third person pronouns were of one origin, as in sense they might well have been, the *k* has a stronger claim by far than any of the others, *p, t, s, h*, or zero. Then, as to the end of the word, it will be found that on every side a final nasal presents itself. The Greek exhibits such a letter in *τιν- (n. τις)*; the Latin in *un-de, alioquin*; the Spanish in *quien*; the Portuguese in *quem*; the Swedish in a nom. *hwem*, gen. *hwems*; the Dutch in a gen. *wiens*; the English in *when-ce* (old *whenn-es*). The Sanskrit grammarians, again, insist that the base of their relative is *kim*, not *ki*; and beyond the limits of our family, as usually defined, the Finn has *ken* for the relative as well as *cu*; and the Turkish *kim*, as well as *kih* and *ki*. Then, again, for the forms which prefer an *s*, the Norse relative is *sem*; the Danish *som*, still retained in our own despised *how-som-ever*. The Slavonic forms for "this" or "that" are *ten* and *sen* in Bohemian, *tom* in Russian. The Norse, for its personal pronoun masculine, has N. *hann*, ae. *hann*, gen. *hans*, dat. *honum*; and for the definite article the same language has a final *n* in the nom. m. f. *en*, and carries this *n* into every oblique of all genders and both numbers. With this evidence so strongly converging to one point,—namely, the syllable *ken*—the question is, what did this *ken* originally denote? One cannot but answer that our own obsolete *ken* in the sense of "look" supplies that meaning of all others which is best fitted to be the origin of demonstrative pronouns. The one difficulty is, can we establish the antiquity of this verb? Something has been already said on this point. It has been traced to the Latin and Greek as the

root of *gnosco, gnovi, agnitus, cognitus*. But it also occurs as a particle in Latin, but of course in a reduced shape; for when verbs are degraded to such an office they are always reduced, as in our own *lo*, for *look*. The particles alluded to are *en*, "behold," and the suffix *ce*, attached exclusively, as it well might be, to demonstratives, as to *hi-c, illi-c, isti-c, si-c, nun-c, tun-c*, or, in fuller form, *hun-ce, hi-ci-ne*. Lastly, for the antiquity and wide extent of the verb *ken*, we need but add, that it exists in Chinese with the very sense desired. It has been thought right to enter into these details in order to establish a point so utterly opposed to the doctrine of pronominal roots as taught by Bopp, and too readily adopted by his followers; and by way of enlivening a subject which to many may appear dull, it may be noticed that occasionally the force of a Latin sentence is brought out more vividly by recurring to the primary meaning of *hic* and *ille*. Thus, in Terence, 'Haut.' 3, 1, 1, *Luciscit hoc iam*—"It is getting light, look, already;" and in 'Virg.' 5, 457, *Præcipitemque Daren ardens agit æquore toto, Nunc dextra ingeminans ictus, nunc ille sinistra*—"Now with his right redoubling blows, now, look, look, with his left."

The classification of the languages of the world is as yet in a very imperfect condition, as might be expected from the fact that a very small portion of them have yet come fairly within the reach of science. Of the great majority, we possess but short vocabularies, and those obtained under circumstances which justify a strong doubt of their value. It is therefore a matter of but ordinary prudence to abstain from all definite theories as to languages of which so little is known. The Indo-European family is in a very different position. Belonging for the most part to highly civilised societies, each member of this family has at least a dictionary and grammar; and having been long under the scrutiny of men of science, they have severally yielded results of value. Yet even here a too hasty generalisation has been made. It was long before the Keltic branch was admitted to its full rights as a member; and philologists of the German school still draw a line of absolute division between this family and other languages, the accuracy of which the unfettered inquirer must be permitted to doubt. The Finn and Lapp family, for example, are found to have affinities with the Indo-European stock, which are not to be explained by their being so closely in contact with the Scandinavian races, for over and above those importations which are sure to take place where barbarism borders on civilisation, there are coincidences which this contiguity will not explain, such for example as between the Lapp *mocum, tocum, socum*, and the equivalent forms in the Latin *mecum, tecum, secum*, for pronouns and simple prepositions are precisely the sort of articles which are never imported. Again in Norse the negative is *ei*, *eigi*, in Danish *ikke*; and in Finn *ei, eikä*. The personal endings of a Lapp verb also bear a close resemblance to those of our Indo-European family. Thus the plural of the verb *molso* "change" runs, *molsoimen, molsoite, molsoin*. The interrogative and relative in Finn have generally the form *cu*, with suitable affixes for the cases, &c. Again the verb *lasken*, "let go," and its diminutive form *laskelen*, "let go by little and little," exhibit both in the main syllable and in the suffix *el*, what is strikingly like words in the great European family. Lastly, as the Latin by adding the particle *que* to the relative creates *quisque*, so in Finn the addition of a syllable not unlike *que* to the relative *jo*, that is, *yo* (so like the Sanskrit *ya*) produces *joca*, "every one." In truth a community of pronouns with the Indo-Teutonic family may justly be claimed for several languages which lie far outside the limits as yet assigned to it. To hint at a connection between our family and the Semitic, would shock the ears of most German philologists; and it must be admitted that a sad amount of rubbish in this way affords some excuse for the prevalent dogmatism; yet the two Hebrew numerals *shish* and *shib'* for "six" and "seven," raise, to say the least, a strong suspicion of some affinity, though, no doubt, it must be a most distant affinity. Be this as it may, the Chinese exhibits so many evidences of identity in important words with the Indo-European family, two examples of which have been here given, that some relationship must assuredly exist; and to connect two such remote families is virtually to draw into the circle many others.

In this problem of comparing languages for the purpose of testing their relationship, the first duty is to carefully analyse the words under comparison, so as to separate the essential from the non-essential, secondly to study the laws of letter-change which must subsist between the languages, if any close affinity exist. A mere identity of form, even with identity of meaning, may be the result of mere accident. On the other hand a real identity often exists when the words have apparently nothing in common. Thus, our English *much* and Sp. *mucho* have the same meaning, yet are utterly unconnected; for the law of letter-change leaves not a doubt that *mucho* is the Latin *multo*, Italian *molto*, a word intimately connected with the Greek *πολ-υ, πολλοι*, and so with *πλεον, πλεον, plus*, as well as with the English *fill* and *full*; just as the Spanish *cuchillo* is the Latin *cultello*; whereas the English *much* and its diminutive *muckle* or *mickle* represent *mag* of the Latin *mag-no-* and the Greek *μεγαλη*. Very different is the position of our *such*, and its Latin equivalent *tali-*. Here, utterly different as are the forms, the words are one in origin, *such* being a corruption of *solch*, as seen in the German *solcher*, and this a compression from *selich-*; while *tali-*, like so many Latin words, has lost a final guttural, and so represents *ta-lík*. Thus, the only serious difference lies in the interchange of *s* and *t*, a question already considered for the pronouns.

Indeed, had we started from the Scotch equivalent of our *suck*, namely, *thilk*, the passage to *tali* would have been too easy to need a word of discussion. As a last example let the Latin *corulus* be compared with the English *hasel*. Here, the words being of the same sense, the form alone needs consideration; but Lat. *c=h*, *r* in Latin has always grown out of an older *s*, and *u* before *l* is the habit of Latin, as *e* before *l* is the habit of English.

The Indo-European family consists of, 1. The Indian branch, with Sanscrit at its head, and Pali, or the sacred language of Ceylon, as an important member. 2. Persian, at the head of which stands the ancient Zend. 3. The Slavonic, which must be subdivided into: *a*, Old Slavic, or the Church language, Russian, Illyrian, Croatian, and the dialects of Carniola, Stiria, and Carinthia; *b*, Slovak of Hungary, Bohemian, the Serbian of Upper and Lower Lusatia, and Polish. The characters which distinguish these two subdivisions are given by Dobrowsky in the preface to his 'Institutiones.' 4. Old Prussian, Lithuanian, Lettish. 5. The Teutonic, divided into three classes: *a*, Scandinavian, including old Norse or Icelandic, Danish, and Swedish; *b*, Low German, including Gothic, old Saxon, old Frisian, Dutch and

Flemish, Anglo-Saxon and English, &c.; *c*, High German, or simply German, in its three varieties of old, middle, and new. 5. Greek. 6. Italian, including: *a*, of old time, Latin, Oscan, and Umbrian; *b*, modern or Romance, that is, Italian, French, Spanish, Portuguese, Norman-English, and Wallachian. 7. Keltic, divided into: *a*, Irish, Gaelic, Manx; *b*, Welsh, Cornish, Breton.

The Turanian family consists of: *a*, Turkish, Mongolian, Mandshoo; *b*, Hungarian; *c*, Finn, Lapp, Ostiak, Syriaen, &c.

To the Semitic family belong Arabic, Hebrew, Syriac, Chaldee, Galla, and Berber.

The remainder may be left for the present unclassified.

The following tables are deduced chiefly from Pott's 'Etymologische Forschungen,' Bopp's 'Vergleichende Grammatik,' and Grimm's 'Deutsche Grammatik.' Other valuable works which may be consulted with advantage, are Zeuss 'On the Grammar of the Celtic Languages,' Diez 'On the Romance Languages,' Schleicher 'On the Lithuanian,' Dobrowsky's 'Institutiones' on the Slavic family, and generally the Proceedings and Transactions of the Philological Society of London.

LANTANURIC ACID ($C_6H_4N_2O_6$). A peculiar acid obtained by the action of ferrocyanide of potassium upon uric acid. It is probably identical with allanturic acid.

LANTERN. [SKYLIGHT.]

LANTERN, MAGIC. [MAGIC LANTERN.]

LANTHANUM (La). A metal discovered in 1839 by Mosander, in what had been previously supposed to be entirely oxide of cerium. He called it lanthanum, from its having so long escaped notice

(λανθάνειν, to lie hid). It is prepared by calcining the mixed nitrates of cerium and lanthanum; by this the oxide of cerium becomes insoluble in dilute acids, and the oxide of lanthanum, which is a powerful base, may be extracted by nitric acid diluted with 100 parts of water; when an alkaline carbonate is added to the nitrate of lanthanum, the carbonate of the metal is precipitated. Oxide of lanthanum is not reduced to the state of metal by potassium, but that metal separates a gray metallic powder from the chloride of lanthanum

which oxidises in water with the evolution of hydrogen gas, and is converted into a white hydrate.

Oxide of lanthanum, in the purest state in which it has hitherto been obtained, is nearly white or of a light salmon colour without any admixture of brown, or brownish red; there is every reason to believe that the colour is owing to some impurity, from which it has not been hitherto possible to free it. It undergoes no alteration by calcination at a red heat in close vessels; it restores the blue colour of reddened litmus-paper; when sprinkled with water, it is gradually converted into a hydrate, and becomes a bulky white powder; this alteration occurs very rapidly in boiling water; it dissolves very readily in acids, even when dilute; when boiled in a solution of chloride of ammonium, it expels ammonia and an ammonio-chloride of lanthanum is formed. The equivalent of lanthanum is 46.4. Hydrate and carbonate of lanthanum are both insoluble in carbonate of ammonia.

Oxide of Lanthanum (LaO). Lanthanum seems to combine with oxygen in one proportion only; this oxide dissolves in hydrochloric acid without evolving chlorine.

Chloride of Lanthanum (LaCl). When a solution of oxide of lanthanum in hydrochloric acid is evaporated over sulphuric acid, prismatic crystals of chloride of lanthanum of a rose-colour are obtained; it deliquesces on exposure to the air, readily dissolves in alcohol, to the flame of which it imparts no colour. This salt melts in its water of crystallisation, gives off hydrochloric acid, and leaves a mixture of chloride and oxychloride of lanthanum.

Nitrate of Lanthanum (LaO,NO₃) is obtained by dissolving the oxide in nitric acid. It crystallises with difficulty, and forms a rose-coloured saline mass which is deliquescent and soluble in alcohol; the form of the crystal is a prism, and it contains no water of crystallisation.

Carbonate of Lanthanum (LaO,CO₃). The neutral compound is obtained by precipitating the soluble salts of lanthanum with carbonate of soda. It is a white flocculent precipitate, which on drying becomes a white adherent powder.

It has been found by Mosander that a mineral, which was supposed to be a protocarbonate of cerium, contained only a trace of this metal, and consisted almost entirely of a compound of 1 equivalent of carbonic acid with 3 equivalents of oxide of lanthanum.

Sulphate of Lanthanum (LaO,SO₃+3Aq). Dilute sulphuric acid very readily dissolves the oxide; by evaporation, acicular radiating amethystine-coloured crystals are obtained. Possibly however the red colour is due to didymium. This salt gives off water, but does not melt at a low red heat.

Double nitrate of Lanthanum and Magnesium (LaO,NO₃+MgO,NO₃+8Aq). Dilute nitric acid is saturated with equivalent proportions of oxide of lanthanum and magnesia, and the solution left to spontaneous evaporation over sulphuric acid. After a time large, shining, white, crystals are deposited: they possess a sweet styptic taste, and are only very slightly deliquescent.

The salts of lanthanum give white precipitates with phosphoric and oxalic acids and ferrocyanide of potassium, but neither hydrosulphuric acid nor tincture of galls produces any change.

LAOCOON, according to ancient fable, was the son of Priam (according to some, of Antenor), and a priest of Apollo, or as some say of Poseidon, during the Trojan war. While offering, in the exercise of his office, a bullock to render Poseidon propitious to the Trojans, two enormous serpents issued from the sea, and, having first destroyed his two sons, whom he vainly endeavoured to save, attacked Laocoon himself, and, winding themselves round his body, crushed him to death in their folds. This dreadful punishment was inflicted by the goddess Athene for the part Laocoon had taken in endeavouring to dissuade the Trojans from admitting into Troy the fatal wooden horse, which the crafty Greeks had consecrated to Athene.

An enduring celebrity has been gained for this story from its forming the subject of one of the most remarkable groups in sculpture which time has spared to us. It represents the agonised father and his youthful sons, one on each side of him, writhing and expiring in the complicated folds of the serpents. The figures are naked, the drapery that is introduced being only used to support and fill up the composition. This superb work of art, which Pliny describes inaccurately as consisting of only a single block of marble, is formed of five pieces of marble (but in spite of this mistake there seems to be no doubt in the opinion of the learned that this is the identical group alluded to by Pliny), originally decorated the baths of Titus, among the ruins of which, on the side of the Esquiline hill, it was found in the year 1506. The names of the sculptors who executed it are also recorded. Pliny (xxxvi. 5) says, "Laocoon, which is in the house or palace (*domo*) of the emperor Titus, is a work to be preferred to all others, either in painting or sculpture. Those great artists Agesander, and Polydorus, and Athenodorus, Rhodians, executed the principal figure (*eum*), and the sons, and the wonderful folds of the serpents, out of one block of marble."

There has been much difference of opinion among antiquaries on several points connected with this group: first, as to the date of the artists; Winckelmann contending that they are of a good period of Greek art, and as early as Lysippus: the next question discussed has been, whether the sculptor was indebted for the subject to Virgil's fine description ('Æneid,' ii., v. 200), or whether the poet was indebted to

the artist. With respect to date, the most careful consideration seems to fix these sculptors as late as the early emperors; and Lessing, whose work on the Laocoon deserves the attention of all who take an interest in the philosophy and capabilities of art, believes that they lived in the reign of Titus. With regard to the subject, it is most probable that the story, being well known, offered advantages for illustration to the sculptor, as it did for description to the poet. As Virgil's priest was habited in his robes during the exercise of his priestly functions, and the group under consideration is entirely naked, the argument is additionally strengthened against the assumption that the artist borrowed from the poet. It is more natural to believe that both drew from a common source, and treated the subject in the way they considered best adapted to the different arts they exercised; the sculptor's object being concentration of effect, the poet's amplification and brilliant description.

This group is justly considered, by all competent judges, to be a masterpiece of art. The subject is of the most affecting and interesting kind; and the expression in every part of the figures reaches, but does not exceed, the limits of propriety. Intense mental suffering is portrayed in the countenances, while the physical strength of all the three figures is evidently sinking under the irresistible power of the huge reptiles wreathed around their exhausted limbs. One son, in whose side a serpent has fixed his deadly fangs, seems to be fainting; the other, not yet bitten, tries (and the futility of the attempt is faithfully shown) to disengage one foot from the serpent's embrace. The father, Laocoon himself, is mighty in his suffering: every muscle is in extreme action, and his hands and feet are convulsed with painful energy. Yet there is nothing frightful, disgusting, or contrary to beauty in the countenance. Suffering is faithfully and strongly depicted there, but it is rather the exhibition of mental anguish than of the ugly and undignified contortions of mere physical pain. The whole of this figure displays the most intimate knowledge of anatomy and of outward form; the latter selected with care, and freed from any vulgarity of common individual nature: indeed the single figure of Laocoon may be fairly referred to as one of the finest specimens existing of that combination of truth and beauty which is so essential to the production of perfect sculpture, and which can alone insure for it lasting admiration. The youths are of a smaller standard than the proportion of the father; a liberty hardly justifiable, but taken probably with the view of heightening the effect of the principal figure. The right arm of the figure of Laocoon is a restoration. Some have thought that the original action was not extended, but that this arm was bent back towards the head; and have supported their hypothesis by the fact of there being a rough and broken surface where they think the hand, or perhaps a fold of the serpent, may have come in contact with the hair.

It has been stated that the group was found in Rome in the year 1506. There is a curious letter, not generally known, but published by the Abbate Fea, from Francesco da San Gallo to Monsignore Spedalengo, dated 1567, in which the circumstances of the discovery are alluded to. He says, "It being told to the Pope that some fine statues were found in a vineyard near S. Maria Maggiore, he sent to desire Giuliano de San Gallo (the father of the writer) to go and examine them—that Michel Angelo Buonarrotti being often in their house, San Gallo got him to go also; and so," says Francesco, "I mounted behind my father (*in groppa a mio padre*), and we went. We descended to where the statues were; my father immediately exclaimed, 'This is the Laocoon spoken of by Pliny.' They made them enlarge the aperture or excavation so as to be able to draw them out, and then, having seen them, we returned home to dinner." The group of 'Laocoon and his Sons' is now preserved among the treasures in art in the museum of the Vatican at Rome. A very fine cast of it is in the Greek court of the Crystal Palace, Sydenham.

LAPIDARY WORK. The work of the lapidary is that of reducing, shaping, grinding, and polishing small hard pieces of stone, especially those which go by the names of gems or precious stones. Such stones require different modes of treatment according to their hardness. The diamond, sapphire, ruby, chrysoberyl, and zircon rank among the very hardest; the agate, amethyst, aquamarina, bloodstone, carnelian, carbuncle, cat's-eye, chalcedony, chrysolite, chrysoprase, crystal, emerald, felspar, flint, fluor-spar, garnet, granite, jade, jasper, lapis-lazuli, onyx, opal, porphyry, quartz, sardonyx, serpentine, and topaz, though differing much among themselves in hardness, may be considered as occupying a sort of medium rank; while a softer class of minerals and vitreous substances is that which includes alabaster, cannel coal, coral, enamel, glass, jet, lava, malachite, mother of pearl, satinstone, steatite, &c. It is by means of small revolving wheels that these are cut and polished by the lapidary. The wheels are of iron, lead, wood, and other substances. For cutting, the edge of the wheel is sharp, and is touched with moistened diamond powder, emery powder, or some similar material; and the edge then acts like an exquisitely fine saw, which works its way through the hardest gems when applied to it. For polishing, the gem or stone is held more frequently against the side of the revolving wheel, or else against buff-leather fixed to the edge of a broader wheel. One of the most delicate examples of lapidary-work ever executed was the shaping of the world-renowned *Koh-i-noor*, or "mountain of light," the large diamond obtained by Queen Victoria from the chief of the Punjab. This jewel, large and fine as it is, was found to have been badly cut and faceted; Professor Tennant

and the Rev. Mr. Mitchell, on having the subject submitted to them, reported that the brilliancy of the diamond might be increased by a careful re-cutting. Messrs. Garrard were entrusted with the work; they engaged the services of M. Coster of Amsterdam, the most highly-skilled diamond-cutter in Europe; Messrs. Maudslay and Field made a small steam-engine, and constructed a revolving apparatus, expressly for the purpose; and the late Duke of Wellington cut the first facet, as an amateur who took great interest in the matter, a few months before his death in 1852. The process of wholly re-shaping the diamond occupied several weeks, on account of the extreme precautions necessary in dealing with a gem of such enormous value. Elaborate as the arrangements were, the lapidary-work was essentially the same in this as in other instances—the friction of a rapidly revolving metal wheel moistened with diamond-powder and water.

The practical applications of the art will be found illustrated in such articles as *CAMEO*; *GLASS MANUFACTURE*, *Glass-engraving*; *INTAGLIO*; and also in some of the mineralogical articles in the *NAT. HIST. DIV.*

LAPSE. [*BENEFICE*; *LEGACY*.]

LARCENY (*latrocinium*, Latin; *larcin* French) is the legal term for theft.

This crime was formerly divided into grand and petty larceny, distinguished by the value of the property taken at one and the same time. It was grand larceny where the value was more than twelve pence; petty larceny where the value did not exceed that amount: a distinction referable to times in which twelve pence was more than equivalent to as many shillings of the present currency. At common law the punishment of petty larceny was whipping or imprisonment; that of grand larceny was death, unless the offender were in a situation to claim benefit of clergy, of which mode of escaping punishment neither women, nor men who were unable to read, or who had been twice married, or who had married widows, or who, not being actually clergymen, had before taken the benefit of clergy, could avail themselves. [*BENEFIT OF CLERGY*.]

By 7 & 8 George IV., c. 28, the distinction between grand and petty larceny was abolished: and larcenies are now distinguished as simple or compound, sometimes called mixed, larcenies.

I. Simple larceny at common law is committed by wrongfully taking, against the will of the owner, and carrying away the goods of another, with the fraudulent and felonious intent wholly to deprive him of his property therein.

First, there must be a wrongful taking against the will of the owner, which taking may be either actual or constructive. Actual taking against the will of the owner is where goods are taken directly either out of the possession of their absolute owner, or out of the possession of a bailee, or temporary owner. Constructive taking against the will of the owner is either where the possession of goods is obtained from the owner with a preconceived intention on the part of the person to steal them, in which case the original taking is felonious, or where the owner, without divesting himself of the legal possession of the goods, delivers them into the hands of a person who afterwards converts them to his own use or to some other purpose inconsistent with the continuance of the owner's property therein, in which case such conversion constitutes the felonious taking. The doctrine of constructive taking has given rise to many nice distinctions. Generally speaking, there can be no larceny where the possession is voluntarily parted with. Thus, if I lend another my horse for a certain period, and he sells the horse, it is no larceny, but a civil wrong, for which the only remedy is by action. But where the possession of a horse is obtained on the pretence only of borrowing, and with the intent to keep or sell him, such parting with the possession by the owner will not diminish the criminal responsibility of the taker. Larceny is not committed when the possession is obtained in the first instance *bonâ fide* without any fraudulent intention. Thus where A saves goods from a house on fire, and takes them home, having at the time an honest intention of preserving them for the owner, although the next morning A conceals the goods and denies having had the possession of them, it is a breach of trust, and no felony; and when goods or money are lost, the converting of them by the finder to his own use does not amount to larceny, unless, at the time of conversion, he knows, or has the means of knowing, who is the real owner. Where however the absolute or temporary owner bails or delivers goods to another, but retains the beneficial possession of them, a conversion of the goods by such bailee to his own use will be larceny. A servant entrusted with his master's goods, a shepherd with sheep, &c., who embezzles them, is guilty of larceny at common law, because in such cases the possession of the servant, &c., is in law the possession of the master; but a clerk, or servant, receiving money or goods from a third person, and misappropriating the same, is not guilty of larceny, because the goods, &c., never were in the possession of the master. If the owner is, by whatever means, induced willingly to part with his *property* in the goods, and not merely with the possession of them, the offence does not amount to larceny; as where possession of goods is obtained under colour of a purchase actually completed, although with an intention of running off without paying for them. But where the owner of a horse on sale allows his paces to be tried by a person who mounts and rides off with the horse, it is larceny, as the owner never parted with the property, nor indeed with the possession, for goods in the presence of the owner are in law considered as in his possession,

though used by another. Where A goes to B's shop in the name of C, and asks for a hat which C has ordered, and it is delivered to A, who converts it to his own use, it is no larceny, because by such delivery B parted with the *property* in the hat. But if upon A's asking for the hat, B had delivered two hats for C to choose from, and A had converted both or either to his own use, the offence would have been larceny, because B parted with the possession only, and not with the property, as the right of property would have remained in B until C had made his election, and the bare possession was obtained fraudulently. In cases of this description where the property is parted with, the offender is guilty of the statutable misdemeanor of obtaining money by false pretences. (7 & 8 Geo. IV. c. 28, s. 53.)

Various other statutes have been passed to prevent the defeat of justice arising from the application of some of these subtle distinctions in particular cases, as the misappropriations and frauds by bankers, brokers, attorneys, and other agents, and also by trustees (7 & 8 Geo. IV. c. 29, s. 49; 5 & 6 Vict. c. 29; 20 & 21 Vict. c. 54); and the embezzlement by clerks and servants, (7 & 8 Geo. IV. c. 29, s. 49).

Secondly, there must not only be a taking, but also a carrying away, technically called *asportation*, to constitute which the goods stolen must be actually removed from the position which they before occupied. Entire removal, to however slight a distance, is a sufficient *asportation*; as if a thief be detected whilst leading a horse out of a field. So where A goes to an inn, and says to the ostler, "Bring out my horse," pointing to B's horse as his own; whereupon the horse is led out; but before A can mount, B comes up. So where a guest, with intent to steal goods out of an inn, removes them down stairs; or a thief, intending to steal plate, takes it out of a chest and lays it upon the floor, or intending to steal a cask from a waggon, removes it from one end of the waggon to the other. But though there must be an actual removal of every part from its previous position, it is not necessary that each portion of the article stolen should be removed from the space which was previously occupied by other portions of that article. Thus where A in raising a bag from the bottom of a coach-boot removes each part of the bag from the space which that specific part occupied, though the whole bag be not removed from every portion of the space which the bag filled in that boot, the *asportation* is complete. So where A has drawn a book about an inch above the top of B's pocket, B puts up his hand, and A drops the book and it falls back into B's pocket, it is larceny. So where a package is, for the purpose of cutting it open and getting at the contents, merely set on end in the place where it had lain, and the thief is disturbed before he has effected his purpose, the larceny is complete. But where a severance is necessary before the thief can have the entire control over the article, the *asportation* is not complete until such severance is effected; as where goods in a shop are fastened by a string to the counter, or a purse is entangled with keys in the owner's pocket.

Thirdly, the thing taken must be goods; and at common law larceny could be committed only in respect of personal goods. Things real, or things annexed to the soil, technically called the *realty*, or which are connected with the soil and freehold, and which are therefore in legal language, said to savour of the *realty*, were not subjects of larceny at common law. This rule was observed so strictly, that larceny could not be committed by stealing title-deeds, nor by stealing growing corn, grass, trees, &c., unless severed from the *realty* by the thief or by the owner, or by a third person, and taken at another time.

The subject matter of larceny at common law must also have been of things *in possession*, as distinguished from things (technically called *choses*) *in action*, that is, things which are of no intrinsic value, but are capable of being made available by action or demand, as deeds, bonds, bills, notes, and other securities for money, &c.

The objection founded upon the connection of the thing stolen with the *realty* is removed by several provisions of 7 & 8 Geo. IV. c. 29. The stealing of written or printed papers or parchments, being evidence of title to real estate, is made a misdemeanor punishable by transportation for seven years, or by fine or imprisonment, or both. To steal or cut, break, root up, or destroy or damage, with intent to steal, any tree, sapling, or shrub, or any underwood growing in a park, pleasure-ground, garden, orchard, or avenue, or in ground adjoining to a dwelling-house (if the value, or the injury done, exceed one pound), is a felony, and punishable as for simple larceny: so if the trees, &c., be growing elsewhere, and the value or amount of injury exceed five pounds. To steal or break, root up, destroy or damage, with intent to steal, the whole or part of any tree, sapling, or shrub, or any underwood, wheresoever growing, the value of the articles stolen or the injury done being to the amount of a shilling, is punishable on summary conviction by a justice, and for a second offence by imprisonment and hard labour not exceeding twelve months; and if any person so twice convicted afterwards commit any of the said offences, such offender is to be deemed guilty of felony, and is liable to be punished in the same manner as in the case of simple larceny. To steal, or destroy or damage with intent to steal, any plant, root, fruit, or vegetable production, growing in any garden, orchard, nursery-ground, hothouse, greenhouse, or conservatory, is punishable on summary conviction by imprisonment for six months; or by forfeiture, over and above the value of the articles stolen or the amount of the injury done, of such sum not exceeding twenty pounds as to the justices

shall seem meet; a second offence is felony, punishable as in cases of simple larceny.

The same statute makes it felony, punishable as in cases of simple larceny, to steal, or rip, cut or break, with intent to steal, glass or wood-work belonging to any building, or any metal, or utensil or fixture fixed in or to any building, or anything made of metal fixed in land, being private property, or for a fence to any dwelling-house, garden, area, or in any square, street, or other place dedicated to public use or ornament; and it is a felony, punishable as in cases of simple larceny, to steal, or sever with intent to steal, the ore of any metal, or any coal, from any mine, bed, or vein thereof. The stealing of any chattel or fixture let to be used with any house or lodging is made a felony, punishable as simple larceny.

With respect to choses in action, the same statute enacts that if any person shall steal any tally, order, or other security, entitling or evidencing title to any share or interest in any public stock or fund, or in any fund of any body corporate, company or society, or to any deposit in any savings' bank, or shall steal any debenture, deed, bond, bill, note, warrant, order, or other security for money, or shall steal any warrant or order for the delivery or transfer of goods or valuable things, the offence shall be deemed felony of the same nature and in the same degree, and punishable in the same manner as the stealing of any chattel of like value with the share, interest, or deposit to which the security so stolen may relate, or with the money due on the security so stolen or secured thereby, or with the value of the goods or other valuable thing mentioned in the warrant or order. It also enacts that if any person shall steal, or shall, for any fraudulent purpose, take from its place of deposit or from any person having lawful custody thereof, or shall unlawfully or maliciously obliterate, injure, or destroy any record, writ, return, panel, process, interrogatory, deposition, affidavit, rule, order, or warrant of attorney, or any original document belonging to any court of record, or relating to any matter, civil or criminal, begun, depending, or terminated in any such court, or any bill, answer, interrogatory, deposition, affidavit, order, or decree, or any original document belonging to any court of equity, or relating to any cause or matter in any such court, the offence shall be a misdemeanor, and subject at the discretion of the court to transportation for seven years, or such other punishment by fine or imprisonment, or by both, as the court shall award. And the stealing, or, for any fraudulent purpose, destroying or concealing a will or other testamentary instrument, is a misdemeanor punishable by transportation for seven years, or by fine or imprisonment, or both.

No larceny can be committed of things which are not the subject of property, as a human corpse, or of things the use of which is common to all mankind, as running water, wild animals in their natural liberty, &c. It is otherwise of animals which are dead, or are reclaimed or confined, and which are useful to man as food or otherwise. But the stealing of dogs, cats, and ferrets, though tame and valuable, and of bears, monkeys, &c., though reclaimed or confined, does not amount to larceny. The stealing of dogs and of beasts and birds, ordinarily kept in a state of confinement, is made cognisable by justices of the peace. (7 & 8 Geo. IV. c. 29; 8 & 9 Vict. c. 47.) And it is a felony, punishable as in cases of larceny, to course, hunt, snare, or carry away, or kill, or wound deer kept or being in the enclosed part of a forest, chase, or purlieu, or in enclosed land in which deer are usually kept. If in an unenclosed part, the offence is made cognisable by a justice of the peace, with power to impose a pecuniary penalty not exceeding 50*l.*; and a second offence, whether of the same description or not, is made felony, punishable as simple larceny. (7 & 8 Geo. IV. c. 29, s. 26.)

Fourthly, the goods taken should generally be the goods of another person.

If a man take his own goods supposing them to be the goods of another, no larceny is committed. It is otherwise where the taking is for the purpose of fraudulently charging another with the loss; as if a man steal his own goods for the purpose of charging the bailee. If a wife take and convert to her own use the goods of her husband, they being but one person in law, it does not constitute larceny.

A joint tenant or tenant in common of any personal chattel cannot commit larceny respecting such chattel as against his co-tenant. But if such chattel be bailed or delivered to the care or keeping of a third party for safe custody, and the effect of the taking be to charge such bailee, it amounts to larceny.

Stealing oysters or oyster brood from a marked-out or known oyster bed, laying, or fishery, is made larceny by 7 & 8 Geo. IV. c. 29, s. 36.

Fifthly, there must be an intent wholly to deprive the owner of the goods stolen of his property therein, which intent constitutes the fraudulent and felonious character of the act. The most common motive for a theft, and the ordinary mode of depriving the owner of his property in the thing stolen, are the conversion of it to the use of the taker; and Blackstone and others have considered that such conversion to the use of the thief, or some benefit to be derived to him, is essential to the completion of the offence, agreeably to the definition of *furtum* in the civil law, "*contrectatio rei fraudulosa lucri faciendi causâ*." But it appears to be now settled that a wrongful destruction of the goods taken, whereby the owner is wholly deprived of his property therein, is sufficient to constitute this offence, although no benefit is sought to be derived to the taker. Persons convicted of simple

larceny were, by the 7 & 8 Geo. IV. c. 29, made liable, at the discretion of the court, to be transported for seven years, or to be imprisoned with hard labour for a term not exceeding two years, and, if males, to public whipping in addition to imprisonment; but the punishment of transportation was taken away by the 12 & 13 Vict. c. 11. The court is empowered to sentence the offenders to be kept in solitary confinement for any period not more than one month at a time, or than three months in the space of one year. (7 Will. IV. & 1 Vict. c. 90, s. 5.) Where the party convicted is a person already under sentence for another crime, the court may award the sentence for the subsequent offence, to commence at the expiration of the former sentence.

Larceny by clerks and servants is punishable by penal servitude, or by imprisonment. (7 & 8 Geo. IV. c. 29, s. 46.)

The Post-Office Act, 7 Will. IV. and 1 Vict. c. 36, s. 26, makes the stealing and embezzling of post letters, letter-bags, &c., felony, punishable with a greater or less degree of severity, according to the nature of the offence and the existence or non-existence of a confidential character in the guilty party. [POST-OFFICE.] Stealing in a dwelling-house to the amount of five pounds, or when accompanied by menaces or threats, or when any one is put in bodily fear, is punishable by penal servitude or imprisonment with hard labour. As cattle are necessarily left in fields, and upon commons and wastes, without any person to attend them, the legislature has interfered to protect property of this description by heavier punishments than those inflicted in other cases of larceny. Cattle-stealers were by several statutes excluded from benefit of clergy; and upon the abolition of the distinction between capital and clergyable felonies by 7 & 8 Geo. IV. c. 29, stealing any horse, mare, gelding, colt, or filly, or any bull, cow, ox, heifer, or calf, or any ram, ewe, sheep, or lamb, or wilfully killing such cattle with intent to steal the carcase or skin or any part of the cattle so killed, was made a felony punishable with death. But now, under 7 Will. IV. & 1 Vict. c. 90, and subsequent statutes, the punishment of this offence is penal servitude for not more than fifteen years, or imprisonment not exceeding three years. Housebreaking is another instance of larceny committed under aggravated circumstances. [HOUSEBREAKING.]

A person guilty of larceny may be indicted for the offence at the suit of the crown [INDICTMENT]; and he might formerly have been appealed or accused in a private action brought by the party injured [APPEAL] to punish the offender and obtain restitution. The appeal is now taken away; but the party injured, and indeed any other person, may prefer a bill of indictment without the leave or even the knowledge of the crown or its officers. But the crown may interpose by entering a *nolle prosequi* before judgment, or by pardoning the offender afterwards; whereas, in an appeal, the crown could neither stop the proceedings nor pardon the appellee, whose life after conviction and judgment was wholly at the mercy of the appellant. After conviction the prosecutor may in general maintain an action for the value of the property taken, a right, however, which is seldom exercised, as the offender is seldom possessed of property, and, upon conviction, the property of the felon is forfeited to the crown.

Simple larcenies, where the value of the property does not exceed five shillings, or where the age of the offender does not exceed sixteen, may now be tried and summarily determined, with the consent of the accused person, by magistrates in petty sessions, the punishment in such cases being limited to six months' imprisonment. (10 & 11 Vict. c. 82; 13 & 14 Vict. c. 37; 18 & 19 Vict. c. 126.) Persons *confessing* charges of simple larceny, larceny from the person, or as clerk or servant, may under the last-named statute be similarly punished by the same tribunal. (Blackstone's 'Commentaries,' Mr. Kerr's edition, vol. iv. p. 333.)

II. Compound larceny is where the crime of larceny is accompanied by circumstances which the legislature has considered as aggravating the offence and requiring an increase of punishment.

Stealing from the person of another, whether openly or clandestinely, is a felony now punishable by penal servitude or imprisonment. To constitute this offence, the thing stolen must be completely removed from the person of the owner, though such complete removal is not necessary in cases of simple larceny. It is no answer to the charge, that such force or fear was used as would make the offence amount to robbery. [ROBBERY.]

LARCH: ECONOMICAL USES. The larch and its products are applied to a large number of uses in the arts. The timber is for many purposes more valuable than that of its sister-tree the fir. For instance—it is more free from knots; it is more durable, as the knots which it contains are seldom rotten; it is less liable to shrink; it will not crack with any moderate degree of heat, when in the form of boards or narrow pieces; it is much more tough; and it is susceptible of receiving a much higher polish, developing a grain or texture often singularly beautiful. On all these accounts larch timber has been much sought after in recent years. Railway and canal engineers especially value it, on account of the long period during which it will bear alternations of wet and dry without decay. It has been experimentally determined that when oak and larch posts of equal size are driven into the beds or banks of rivers, the larch rot much less speedily than the oak. On one occasion a plank-bridge was examined after-fifteen years, when it was found that the only planks which had not decayed were those made of larch. It has been found a very valuable sub-

stitute for the more expensive oak in shipbuilding, chiefly in small vessels. As sleepers for railways, axles for mill-work, hop-poles, and stakes for plants in general, larch possesses great value. Especially for railway-sleepers is this usefulness observable; because, as the sleepers are placed on ground subject to frequent alternations of wet and dry, the power of the timber to resist this action becomes a matter of great importance. Larch is not so useful in common house-carpentry as deal, because it is a wood difficult to saw and plane; a less durable wood is selected on account of its ease in working. The use of larch has been much encouraged by the grand operations of the dukes of Athol. About a hundred and thirty years ago, the hills in the Dunkeld and Blair-Athol districts were barren and almost valueless, scarcely worth a shilling an acre for any industrial purposes. James, the duke of Athol of those days, planted a few larches for ornamental purposes, and then planted two thousand more for timber. It was a thought worthy of a great landed proprietor; for it could only be in the time of his successors that the trees would be old enough to cut down for timber. Much difficulty had to be encountered; for the furze, broom, juniper, and heath, greatly retarded the growth of the young larches; but this obstacle was conquered by perseverance. The next duke planted eleven thousand larches between 1764 and 1774; while the son of this latter, in the fifty-two years from 1774 to 1826, planted the enormous number of *fourteen millions*, some of them even on the summits of mountains. It was calculated about the last named date, that during the second half of the present century all these will successively become magnificent timber trees, suitable for ship-building and large engineering operations; and that, if all went well, the planting would virtually be a creation of property to the amount of six or seven millions sterling.

On the continent, larch is applied to a great variety of purposes. The Rhenish wine-casks are made of this wood, and are said to be more durable than any other. In some parts of France and Switzerland houses are built of larch, by placing bulky squared trunks one upon another; the heat of the sun, melting the resin in the wood, causes it to run down the sides and to fill the interstices between the logs, thereby keeping out both air and moisture. Larch is in general use for water pipes in those countries. The larch vine-props are left in the ground for years together; all around them are props which perish year after year, while the larch itself remains sound.

Other parts of the tree are also applied to useful purposes. The bark is used in France and England for tanning. The leaves are eaten by cattle and sheep. The burnt wood yields very heavy charcoal, excellent for iron foundries. Venice turpentine, so called, is obtained from the larch. In certain parts of France, during four months of summer, the obtaining of this turpentine is a regular employment; a full-grown tree yielding in this time six or eight pounds. Incisions about an inch in diameter are made in the trunk of the trees; small troughs or descending channels are placed in connection with these incisions; vessels are placed underneath; and after regular intervals of a few hours, the vessels become filled with clear turpentine.

It may here be mentioned that within the last few years some little-understood disease has affected the larch plantations in many parts of England; and that a volume has just been published on this special subject by Mr. Macintosh, the author of various works on gardening and planting.

LARD. [FAT; UNGUENTS.]

LARES, among the Romans, were household gods; the guardians of their hearths and families. There is much dispute upon the etymology of this term. Apuleius derives it from *Lar*, *familiaris*. Ovid speaks of the Lares as the offspring of Mercury and Lara. From a passage in Virgil's 'Æneid,' ix., 255, it would seem that these Lares of the Romans were the *manes*, or souls of their deceased ancestors: it is certain that their worship was closely connected. According to Ovid ('Fasti,' v., 146) there were generally two of them, who were sometimes represented with a dog at their feet. Others were clothed in the skin of a dog. They were of small size, and generally represented in short habits as ready to minister to the needs of the household, and usually held a cornucopia in their hands as a symbol of good house-keeping. The festival of the Lares was celebrated on the kalends of May (Ibid., v., 129) when they were crowned with garlands and sacrifices were offered to them. In the inner part of large houses there was frequently a Lararium or shrine for the worship of the Lares. Pitiscus records an inscription, 'LARIBVS PRO SALVTE ET INCOLVMITATE DOMVS Q. SERTORII.' There seem to have been two classes of Lares, the *Lares domestici et familiares*, which were the family Manes; and the *Lares publici*, which included *Lares urbani, rurales, viates, compitales, marini*, &c. which presided in the localities indicated by their titles. [MANES; PENATES.]

LARGE, in music, see LONG.

LARGHETTO (Italian), a musical term, a diminutive of Largo [LARGO], slow, but less so than Largo.

LARGO, in music (Ital. adverb, *largely, widely*), is the second in order of the five classes into which musical movement is divided [ADAGIO], and signifies *slowly*.

LARYNGITIS. [CROUP.]

LATENT HEAT. When a body is exposed to the action of heat so as to change its state, as from a solid to a liquid, it rises to a certain temperature, known as its *melting* or *fusing point*, and remains fixed

at that temperature until the whole of the solid shall have been liquefied. [LIQUEFACTION.] During this operation a quantity of heat must evidently enter the body in order to produce liquefaction; and as it produces no effect on the thermometer, it is said to be *combined*, and rendered *latent*, and is also known as the *heat of liquefaction*, or that heat necessary to the liquid state, so that when the body again becomes solid, the heat thus combined is given off in a sensible form.

Latent heat is one of the capital discoveries of Dr. Black. There are various modes of estimating its amount in different bodies, one of which is by means of the calorimeter, an instrument which bears to combined heat the same relation that the thermometer does to sensible heat. The calorimeter was shortly described under HEAT, and will be figured and described under SPECIFIC HEAT. In order to ascertain how much heat is absorbed and rendered latent during the liquefaction of ice, for example, all that is necessary is to place a pound of water of any known temperature in the calorimeter, which is filled with ice, and observe how many degrees the hot water falls through in dissolving a pound of ice. It will be found that the water must give off 142.65° of sensible heat in order to convert ice at 32° into water at 32° . Hence, during the liquefaction of ice, as much heat is rendered latent as would suffice to raise its own weight of water from 32° to $32^{\circ} + 142.65^{\circ} = 174.65^{\circ}$.

Since then a pound of ice at 32° absorbs 142.65° in becoming a pound of water at 32° , it follows that the same quantity of heat is given out or rendered sensible, when the ice again passes into water. There are various modes of proving this: Suppose a vessel of water at 60° be immersed in mercury at 60° below the freezing-point of water, or -28° ; a thermometer in the mercury will rise, and one in the water will fall until the latter indicates 32° . We will call these two thermometers No. 1 and No. 2. No. 2, then, or that in the water, will remain stationary during the freezing; but No. 1 will continue to rise in consequence of the heat which the mercury receives from the freezing water. When all the water has become solid, then, and not before, will the thermometer No. 2 again begin to fall; but the thermometer No. 1 will rise uninterruptedly until both thermometers meet at some point below 32° . The cold of winter is considerably mitigated by the sensible heat which is given out by freezing water, and when the temperature rises with the return of milder weather a considerable portion of the heat is employed in producing liquefaction.

Similar phenomena accompany the liquefaction of other bodies. When a mass of lead, for example, is put over the fire it rises to 620° ; it then begins to fuse, and it remains at that temperature until the whole mass has become liquid: the heat thus absorbed and rendered latent is called the *latent heat of fusion*. The following table gives the latent heat of certain liquids:—

	Fahr.	
Water	142.65°	1.000
Nitrate of soda	113.34	0.794
Nitrate of potash	85.26	0.598
Zinc	50.63	0.355
Silver	37.92	0.265
Tin	25.65	0.179
Cadmium	24.44	0.171
Bismuth	22.75	0.159
Sulphur	16.85	0.118
Lead	9.65	0.067
Phosphorus	9.05	0.063
Mercury	5.11	0.035

It will be seen from the above table, that the latent heat of ice is very considerable, while that of lead is very small: hence ice melts slowly, lead rapidly. Ice cannot melt until it has received as much heat as would raise its own weight of water 142.65° ; while lead melts with as much heat as would raise its own weight of water 9.65° . Did ice melt with the same comparative facility as lead, the first thaw would cause inundations by the sudden melting of the snow and ice of winter.

When a liquid passes into the state of vapour there is a further absorption of heat, still more remarkable than in the case of liquefaction. If heat be applied to water at 32° , the temperature will rise through 180° to the boiling-point, which under mean pressure is 212° . [BOILING OF LIQUIDS.] At this point the water will pass off rapidly in the form of steam, and during the whole of this time the thermometer will remain fixed; or, in other words, the steam will have precisely the same temperature as the boiling water. We can easily calculate the quantity of heat thus absorbed and rendered latent by the steam, by noting the time required to raise the water through the 180° between 32° and 212° , and also by ascertaining how long it took for the boiling water to pass off into steam. Supposing these times were equal, the same quantity of heat must evidently have been employed in the one case as in the other; but what is the fact? It requires $5\frac{1}{2}$ times as long to convert the water into steam as it did to raise it from 32° to 212° ; in other words, the latent heat of steam is $5\frac{1}{2} \times 180 = 990^{\circ}$.

This enormous quantity of latent heat is again given out when steam condenses into water, and hence steam becomes a powerful source of heat. Indeed any given weight of water in the form of steam at 212° , in being condensed, will raise $5\frac{1}{2}$ times its own weight of water from 32° to 212° .

The heat absorbed during the vaporisation is less in proportion as

the temperature of the vaporising liquid is high. A given weight of water vaporised at 212° absorbs less heat than the same quantity vaporised at 180°. It was formerly stated that the increase of latent heat for lower as compared with higher temperatures was equal to the difference of the sensible heats; so that the latent heat added to the sensible heat would always produce the same sum for the same liquid. Taking 950° as the latent heat of steam, as the mean of a number of observers, a certain weight of steam at 212° condensed at 32° gives out 180 of sensible heat + 950° of latent heat = 1130°. The same weight of steam at 250° condensed at 32° gives out 218° of sensible heat, but only 912° of latent heat, still making the sum 1130°. Again, the same weight of steam at 100° condensed at 32° gives out 68° of sensible heat, but as much as 1062° of latent heat, making together, as before, 1130°. M. Regnault, in examining this question, has found however that the sum of the latent and sensible heats is not constant, but increases by a small though constant difference, equal for each degree to an increase of 0.305° Fahr.

Water furnishes a much larger amount of vapour, bulk for bulk, than any other liquid: a cubic inch of water at 212° expanding to 1696 times its volume, or nearly a cubic foot of steam at the same temperature; whereas a cubic inch of alcohol, boiling at 173°, forms only 528 cubic inches of vapour; ether, boiling at 95°, produces only 298 cubic inches of vapour; and oil of turpentine, boiling at 314°, produces only 193 cubic inches of vapour. Now, although the latent heat required to convert such liquids into vapour is much less than that required to convert water into steam, no advantage would be gained in employing them as prime movers, supposing they were as cheap as water, on account of their low expansive force, which must evidently depend on the bulk of vapour produced from a given bulk of liquid.

The determination of the latent heat of vapour is a difficult and delicate inquiry. The subject has been investigated of late years by Professor Andrews, Favre and Silbermann, and others; and we may here shortly state the method adopted by Andrews. The liquid which is to supply the vapour is placed in a flask, the neck of which has a short bend, and is connected with a glass receiver with a spiral condensing-tube immersed in a large quantity of water, the weight of which has been accurately determined. The liquid being distilled over into the receiver, the quantity that condenses is carefully weighed, and the rise in temperature experienced by the water surrounding the receiver is carefully noted. In this way the amount of heat rendered latent is determined by converting a given weight of the liquid into vapour, and then condensing such vapour by means of water, the temperature of which is known before and after the experiment. The following table of the latent heat of vapours is selected from a larger one contained in the new edition of the 1st part of Professor Miller's 'Elements of Chemistry,' 1860:—

Substances.	Equal Wts.	Equal Wts.	Equal Wts.	Equal Vols.	Observers.

LATH. In building operations two descriptions of laths are commonly used; the first of which are cut out of sawn plank, and the second are split in the direction of the grain of the wood out of timber especially converted or selected for this purpose. The sawn laths are used to receive slates, or tiles, and are usually (as a maximum) 4½ inches in width, laid to a gauge, (or at certain distances measuring from edge to edge) dependent upon the sizes of the slates or tiles themselves. The split laths, whether of fir or of oak, are used for plasterers' work, and they are nailed upon the joists, or quarters of partitions, so as to leave a small interval into which the rendering coat may be forced in a manner to form a key to support the rest of the work. In France and generally upon the continent oak laths are almost exclusively used; whereas in England none but fir laths are to be obtained; they are from 3 to 4 feet long.

The small strips of wood, laid between packages in warehouses, are also known in trade by the name of laths. Plasterers' laths are called *single* when about ¼ of an inch thick; *lath and a half* when about ½ of an inch thick; and *double*, when they are about ¾ of an inch thick.

LATHE. [EARTHENWARE; POTTERY; TURNING.]

LATINUM JUS, JUS LATII, LATINITAS, sometimes also called

simply **LATIUM**, was one of the various civil conditions under which the inhabitants of the Roman world were classed and comprised. The primary distinction of persons was that of freemen and slaves. Freemen were divided, according to the Roman polity, into 1. *Cives Romani*; 2. *Latini*; 3. *Peregrini*, or aliens. The Roman citizen lived under the civil law of Rome, which determined his rights and duties, and he might aspire to the offices and honours of the Roman state.

The rights and duties of those who came under the second of these heads, the *Latini*, were defined by the *Jus Latinum*. They formed a considerable and important class, and ranked next to the Roman citizens in privilege. This class, however, was differently formed, and enjoyed different rights at various periods of the history of Rome.

The old inhabitants of Latium, whilst they continued *foederati* or confederates of Rome under the Cassian treaty, enjoyed several of the rights of Roman citizens. The rights of a Roman citizen were of two sorts, private, or civil, and public, or political. The principal private rights were the *jus libertatis*, or personal freedom, by which the Roman citizen was master of his own person, could not be arbitrarily imprisoned nor punished, except after legal trial, and could not be scourged on any account; the *jus connubiorum*, by which he was enabled to contract a legal marriage with a Roman freewoman, or with those *Latinæ* or *Peregrinæ* who enjoyed the privilege of the *connubium*, and by which his children were also Roman citizens; the *jus patrum*, the consequence of the *connubium*, which gave him that unbounded authority over his children which was peculiar to the Roman law, and which no other people were possessed of (Gaius, i. 55; Justinian, 'Institutiones,' i. 9); the *jus legitimi dominii*, which included the ability of acquiring property, by testamentary gift, *mancipatio* or *nexum*, *usucapion*, *cessio*, &c.; and the *jus testamentorum*, by which he was enabled to bequeath property by will.

The chief public or political rights were, the *jus census*, or having his name registered in one of the tribes and *centuriæ*; the *jus suffragiorum*, or right of voting in the *comitia*; the right of appeal to the *comitia* from the sentence of the magistrate; and the *jus honorum*, by which he was enabled to aspire to any of the dignities in the state. Now the freemen of the Latin confederate towns lived under their own laws and therefore were not under the civil law of Rome; they had their own forms of marriage, of testaments, &c., which were valid in their own courts, but not at Rome; they had not the same paternal authority as the Romans over their offspring; they could not purchase, possess, or inherit property at Rome or in the Roman territory; their persons were not under the protection of the Roman law; they might be sent away from Rome, and they and the other Italian *socii* were sent away repeatedly, among other instances, under the consulship of Lucius Crassus and Mutius Scævola, in the year B.C. 96, just before the beginning of the Social war, to which that expulsion greatly contributed. It would seem, however, that all the towns of Latium were not on the same footing in these respects, and that some of them had adopted of their own choice certain Roman laws, and by so doing had become, according to the Roman legal term, "*populi fundi*," that is to say, had entered within the pale of those particular Roman laws, and had the benefit of their provisions even at Rome. (Cicero, 'Pro Balbo,' viii.) Whether the Latin confederates had the *connubium*, or right of intermarriage, has been questioned by some; Niebuhr, however (vol. ii., 'On the Franchise of the Latins') maintains that they had.* As for the public or political rights of Rome which mainly constituted what was called the "*civitas*," the Latins were not "*censi*" at Rome, and they could not aspire to the honours and offices of the Roman state, except those who had previously filled certain municipal offices in their own town for a time, after which, by transferring their domicile to Rome and inscribing their names in one of the tribes, they acquired the *civitas* and all its rights and privileges. It appears also that there were other means by which a Latin or other Italian freeman might obtain the Roman *civitas*, by rendering some important service to the Roman state. With regard to the right of suffrage, it is not clear under what conditions the *municipes* of the Latin cities enjoyed it, but it appears that they came at times to vote at Rome on certain occasions, but then they had no fixed tribe, and voted in a tribe which was drawn by lot, and they might, as it has been said already, be ordered away by the magistrates previous to the day of voting, as was done by the consul Virginius, the colleague of Spurius Cassius. In the year B.C. 123, they came to Rome to vote in favour of the laws

* Notwithstanding all that has been written on the subject, it is not so easy to say precisely what the *connubium* was. The only intelligible definition is that of Gaius (i. 56), who, when speaking of the marriage of a Roman citizen with a Roman woman or with a *Latina* or *Peregrina* with whom the *connubium* existed, observes that the effect of the *connubium* was that the children followed the condition of the father, were consequently Roman citizens and subject to the *patria potestas*. That the like consequence followed if a Latin married a Roman woman, as to the rights of such children as Latin citizens, is merely the corresponding and correlative part of the *connubium*. But that the *connubium* alone enabled a Latin citizen who married a Roman woman to confer on his children the rights of Roman citizens, and himself to acquire the *patria potestas*, seems inconsistent with the notions of Roman citizenship. The subject of the *Jus Latii*, and of the *connubium* in connection with it, is very difficult to understand, and the obscurity is by no means diminished by the way in which Niebuhr has handled it.

proposed by Caius Gracchus, but the consul C. Fannius ordered them away immediately. The civil condition of the Latins, or Jus Latinum, was therefore inferior to that of the Romans, but next to it in importance, and a kind of intermediate step towards obtaining it. They had, even at Rome, some advantages over the Peregrini, or aliens, who were domiciled in that city.

When the Romans began sending out colonies to several towns of Latium, such as Ardea, they probably placed the colonists on the same footing as the old Latin inhabitants, namely, under the Jus Latinum. And afterwards they followed the same system with regard to colonies which they sent to other parts of Italy, and which were called Latin colonies, though this name did not mean that they consisted of Latins, but that the colonists, whether Romans or Latins or from other parts of Italy, were placed, with regard to Rome, on the same footing as the inhabitants of Latium. The two principal advantages of their condition were—1st, that they enjoyed municipal independence, had their own senate, chose their own local magistrates, and were not subject to the Roman prætor; and 2nd, that those who filled important municipal offices for one year in the colony acquired the full right of the Roman civitas, and, by transferring their domicile to Rome, might aspire to all the honours and offices of the republic.

At the time of the second Punic war there were thirty of these colonies in various parts of Italy. Twelve of them, after the battle of Cannæ, being weary of the protracted war, refused to give any further assistance in men and money against Hannibal, saying that the Romans ought to make peace with Carthage. These colonies were Ardea, Nepete, Sutrium, Alba, Carseoli, Cora, Suessa, Circeii, Setia, Cales, Narnia, Interamna. ('Livy,' xxvii. 9.) The other colonies remained faithful, continued to furnish their contingents, and were thus the means of saving Rome from destruction. These, it would appear from a passage of Cicero ('Pro Cæcina,' 35), received as a reward the commercium with Rome, or the faculty of acquiring Quiritarian ownership ('Gaius,' ii. 40), of taking by testamentary gift from Roman citizens, and of making a will according to Roman forms, &c.

When by the Julian law the people of Latium and other allies received the full Roman franchise, the Latin colonies shared also the boon. They obtained the civitas, all their citizens had the same civil rights as those of Rome, and if they came and settled at Rome, they enjoyed all the political rights. At this period therefore the old Latinitas, as a distinct civil condition of part of the inhabitants of Italy, was at an end.

But in the following year, under the consul Cn. Pompeius Strabo, the towns of Transpadane Gaul, which were filled with a mixed population of Italians and Gauls, had adopted the Latin language, and remained faithful to Rome in the midst of the defection of the Social war, were raised to the rank of Latin colonies, though no colonists were sent to them. By this new Latinitas, which was called "Minus Latium," or the "lesser Latin franchise," compared with the old Latinitas, the Transpadane towns continuing to govern themselves according to their own laws, were allowed the commercium, but not the connubium, with Rome; and they obtained such share of political privilege that persons who filled magistracies and offices of honour in such towns thereby acquired the full Roman franchise, and they alone. Afterwards many other towns and provinces were raised to the rank of Latin colonies in the same degree; as, for example, the towns of Sicily obtained it from Julius Cæsar.

This is the Latinitas, or Jus Latinum, which existed in later ages of the republic and under the empire, until Caracalla bestowed the Roman citizenship upon the provinces. The principal conditions of this Latinitas will be found in the following passages of Ulpian. Ulp. Frag. Tit. ii. s. 16, Tit. v. s. 4 & Tit. xix. s. 4, in the last of which there is another kind of Latini mentioned; namely, the Latini Juniani. This was a new kind of Latinitas, introduced by the Lex Junia Norbana, passed under the consulship of M. Junius Silanus and C. Norbanus Flaccus, in the tenth year of the reign of Tiberius, and the twentieth of our era. By this law freedmen who were emancipated without certain forms ('Gaius,' i. 17, 22, &c.) and their offspring were placed not under the Jus Civium Romanorum, but under the Jus Latinum, and this even under peculiar restrictions. They had the commercium, but not the connubium. (Savigny, 'Ueber die Entstehung und Fortbildung der Latinität als eines eigenen Standes im Römischen Staate,' in the 'Zeitschrift für Geschichtliche Rechtswissenschaft,' 4th vol., 2nd No., Berlin, 1823.) Justinian ('Cod.,' b. vii., ch. 6) at last abolished this Junian or individual Latinitas, and as the Latinitas of the colonies had ceased long before, all distinction between Latin and Roman was then at an end.

The great importance which the Romans attached to the grant, not only of the political franchise or suffrage, but also of the connubium and commercium, was an effect of their exclusive policy. When they subdued a confederate people, such as most of the Italian nations were, they left to each town its laws and its local magistrates, but forbade the general assemblies of the nation; they restricted or entirely forbade the intercourse between one town and another, so that the people of each could not marry out of their respective district. They pursued afterwards the same policy in the countries which they conquered beyond the limits of Italy, as in Macedonia, which they divided into four parts, forbidding all communication between them.

We must now speak of the Jus Italicum. Sigonius understood it to be a sort of middle condition, between that of the Latini and that of the Peregrini, or aliens, with regard to Rome. But Savigny contends, and apparently with reason, that the Jus Italicum did not affect single individuals, but whole towns, namely, provincial towns out of Italy, to which it was granted, and that it consisted—1st, in the right of having their own free institutions and administration; 2nd, in being free from tax to Rome; 3rd, in having the ownership of property in the territory of those towns regulated according to the Quiritarian or Roman laws, and consequently subject to usucapion, cessio juris, mancipatio, and vindicatio. This last provision was an important security to property, and it placed the towns Juris Italici above all other provincial towns, whether governed by a prætor from Rome or liberæ, which had not the same right. Towns having the Jus Italicum are mentioned by Pliny in Spain and Illyricum; Constantinople is mentioned in the Theodosian code as enjoying the Jus Italicum, and in the Pandects ('De Censibus,' b. l., tit. 15) other towns are mentioned as possessed of the same right. (Savigny, 'Ueber das Jus Italicum,' in the 'Zeitschrift' above mentioned. See also, on the whole of this intricate matter concerning the Jus Latii and Jus Italicum, Sigonius, *De jure Antiquo Italiae*; Cicero, *Pro Balbo*, with the *Notes* of Grævius and Manutius; Niebuhr's 'History of Rome.')

LATITUDE. [LONGITUDE AND LATITUDE.]

LATITUDE, METHODS OF FINDING. [LONGITUDE AND LATITUDE, METHODS OF FINDING.]

LATUS RECTUM. [ELLIPSE; HYPERBOLA; PARABOLA.]

LAUDANUM. [OPIMUM.]

LAUGHING GAS. [NITROGEN; nitrous oxide.]

LAUGHTER, as physically defined, is an emotion entirely confined to the human species. It is a peculiar agitation of the body, an organical titillation as it were, which, rising suddenly and irresistibly, affects at once the face and throat, the thorax and the abdomen. Although this physical phenomenon is usually more or less loud, it is sometimes almost imperceptible, and only traceable by a slight muscular motion of the face and mouth. It is usually a pleasant sensation, but occasionally, as in cases of hysteria, it assumes a painful character, and is no longer under the slightest control of the will. While however the corporeal phenomenon is so simple, the nature of the mental state, and of the object by which it is produced, is more complicated and debateable. On this subject a great variety of opinions has prevailed. Among the ancients there is more of unanimity than among the moderns. According to Aristotle, the ridiculous is some error in truth or propriety, but at the same time neither painful nor pernicious (τὸ γὰρ γελοῖον ἐστὶν ἀμάρτημα τι καὶ αἰσχρὸν ἀνώδυνον καὶ οὐ φθαρτικόν. 'De Poet.,' 6, § 1). Nearly coincident with the foregoing is the view of Cicero, who, while he declares that the ridiculous is incapable of any rigorous definition, admits that the chief, if not the sole object of laughter, is that which, without impropriety, marks out and exposes an impropriety ("Hæc enim ridentur vel sola vel maximè quæ notant et designant turpitudinem quandam non turpiter;" 'De Oratore,' 2, n. 235). Quintilian considers it to be absolutely indefinable ("Anceps ejus rei ratio est," lib. vi., c. 3). At the same time, by adducing the opinion of Cicero, that the improper and the deformed constitute the province of ridicule, and affirming that ridicule is near allied to contempt ("a derisu non procul abest risus;" *Ibid.*), he approximates to the strong opinion of Hobbes among moderns, according to whom, the source of laughter is "a sudden glory arising from conception of some eminency in ourselves, by comparison with the infirmity of others, or with our own formerly" ('Human Nature,' ch. ix., s. 13). With Hobbes's opinion, that of Helvetius coincides, who makes pride the source of laughter. Beattie and Priestley agree in making the ridiculous to arise out of a misrelation or incongruous union of objects; while Lord Kames considers a contrast to be the essence of the laughable. The latter view is adopted by Mendelssohn and J. Paul Richter. The former ('Dialogue' iii., 'Klein phil. und æsth. Schriften') makes it to be grounded on a contrast between perfection and imperfection, which however must be unimportant and but slightly interesting to us, and must amount to no more than an extravagance or inconsistency. The latter (in his 'Vorschule der Ästhetik,' p. 143) makes the ridiculous to be the contrary of the sublime, and consequently the infinitely small. Closely coincident with this view is that of Campbell ('Philosophy of Rhetoric,' b. i., ch. ii.), who observes that "ridicule in futile objects hath a similar effect to that produced by what is called the vehement in solemn and important matters." Lastly, Kant ('Kritik der Urtheilskraft,' p. 225, 2nd ed.) makes the ridiculous to arise from the sudden conversion into nothing of a long-raised and highly-wrought expectation.

According to Shaftesbury ('Characteristics,' 'Essay on Wit and Humour') ridicule is the test of truth, and he adduces in support of his view the words of Gorgias of Leontini, "Confute ridicule by seriousness and seriousness by ridicule" (τὴν μὲν σπουδὴν διαφθεῖρειν γέλωτι, τὸν δὲ γέλωτα σπουδῇ. Arist., 'Rhet.,' lib. 3, ch. xviii.). In order to adjust the sentence to his own view, Shaftesbury adopts the Latin version, "seria risu, risum seriis discutere;" it is however clear from the context where the passage is quoted, that Gorgias was there recommending an orator to endeavour to remove the impression which his opponent may have made upon his auditors by employing a directly

opposite style of address. But the maxim of Shaftesbury admits only of a negative application, for ridicule, at most, is only fitted to refute error. In truth however it is not properly levelled at the false, but at the absurd in tenets and opinions. The ridiculous is not any fixed and constant property of certain objects, but it is purely relative and dependent upon the subjective states and conditions of individual minds. The simpleton and the boor laugh heartily at what scarcely provokes a smile in the educated man and the sage; and on the other hand, much will excite a laugh in the latter, which would not move a muscle in the face of the former. Such again is the effect of a gay or a gloomy temperament, that a Democritus will laugh where a Heraclitus would weep.

LAUREATE, POET, an officer in the lord chamberlain's department of the royal household. The appellation "laureate" seems to have been derived through the Italian, from the Latin *laurus*, "a bay," in allusion to the ancient practice of crowning poets. Petrarch received the crown at Rome in 1341, and Tasso in 1594. The earliest mention of a poet-laureate in England, under that express title, is in the reign of Edward IV., when John Kay received the appointment. Warton, however, in his 'History of English Poetry,' shows that the poet-laureate is undoubtedly the same officer who in the reign of Henry III. is styled *Versificator regis*, the "king's versifier," and to whom a hundred shillings were paid as his annual stipend. Skelton (writing in the reign of Henry VII.), in three or four of his poems, styles himself "poet laureate;" but the laureateship of which he speaks was a degree granted by the university (in his case of Oxford) for proficiency in 'grammar,' in which versification was included. With the degree was given a laurel wreath. Skelton was one of the last who received this degree. But though

"By hole consent of ther Senate
He was made poete lawreate,"

and in consequence, wore as laureate a suit of white and green, on which the word Calliope was embroidered, he also held the office of 'laureate to the king,' Henry VIII., whose tutor he had been. Ben Jonson is said to have been the poet-laureate to King James I. In the reign of Charles I., 1630, the first patent of this office appears to have been granted, which fixed the salary or pension attached to it at 100*l.* a year, with an additional grant of a tierce of Canary wine from the king's stores; before this there seems to have been no fixed salary, the sum paid being rather in the shape of a gratuity. The succession of poets-laureate since the time of Charles II. has been—John Dryden, Nahum Tate, Nicholas Rowe, Laurence Eusden, Colley Cibber, William Whitehead, Thomas Warton, Henry James Pye, Robert Southey, William Wordsworth (with a salary of 300*l.* a-year), and, since 1850, Alfred Tennyson. A commutation was agreed to of 27*l.* for the allowance of wine, by Southey, while he held the office.

LAURIC ACID. [LAURYL.]

LAURINE ($C_{44}H_{80}O_6$), an acid and bitter principle contained in the berries of the laurel; its smell resembles that of laurel oil. It is insoluble in water, and little soluble in cold alcohol, but more so in boiling alcohol and in ether; it crystallises from solution in needles. When heated it melts, and volatilises without leaving any residue. To sulphuric acid it first imparts a yellow and afterwards a reddish-yellow colour; in cold nitric acid it liquefies, and floats upon the surface; it bears considerable resemblance to solid expressed oils; the berries contain only about 1 per cent. of this substance.

LAURONE. [LAURYL.]

LAUROSTEARIC ACID. [LAURYL.]

LAUROSTEARIN. [LAURYL.]

LAUROSTEARONE. [LAURYL.]

LAURUS NOBILIS, the true (*Cæsar's*) laurel, or sweet bay, *Medical properties of.* Of this tree or large shrub, the berries only are officinal in this country, the leaves and berries on the Continent. Both contain a volatile oil; the berries also a fixed or expressed oil, called laurel fat or oil of bays. The berries analysed by Bonastre yielded: volatile oil, 0.8; laurin, 1.0; fixed oil, 12.8; wax (stearin), 7.1; resin, 1.6; uncrystallisable sugar, 0.4; gummy extractive, 17.2; bassorin, 6.4; starch, 25.9; woody fibre, 18.8; soluble albumen, traces only; an acid, 0.1; water, 6.4; salts, 1.5; ashes, 1.2. The volatile oil can be procured from the leaves or berries by distillation. It consists of two distinct isomeric oils, separable by re-distillation. Laurin is a true camphor, similar to that obtained from other Laurineæ. It may be extracted by rectified alcohol.

The fixed oil may be obtained from either the fresh or dried berries; the latter require to be macerated or exposed to steam previous to being pressed. The most remarkable point in regard to this oil is, the part of the fruit in which it is lodged, viz. —the endocarp, most fixed oils being in the seed, but this fruit, the olive, and a few others, have it in the endocarp.

The bruised leaves, and the berries, are tonic, carminative, and febrifugal; but they are little used in medicine. The fixed oil is in extensive use in veterinary medicine.

It is important to remark that the use of bay leaves, in cookery, to flavour puddings, cheese-cakes, custards, &c., has led in several instances to serious mistakes. In many cases the leaves of cherry-laurel, which contain a volatile poisonous oil, and the elements of prussic acid, are used by cooks as recklessly as bay-leaves—having got

the name simply of laurel, instead of *cherry-laurel*. Even sculptors have encircled the brows of their marble heroes with the wrong leaf.

LAURYL ($C_{24}H_{48}O_2$). An hypothetical radical contained in lauric acid and the compounds derived from lauric acid. It is homologous with acetyl, propyl, butyl, &c. [NEGATIVE RADICALS.]

Hydride of lauryl ($H, C_{24}H_{47}O_2$) is not known, but a derivative of it, termed *laurone*, or *laurostearone*, has been obtained by the destructive distillation of laurate of lime. It is a crystalline body: melting point 151° Fahr. It contains ($C_{22}H_{42}, C_{24}H_{44}O_2$), the electropositive hydrogen in hydride of lauryl being replaced by the electropositive radical ($C_{22}H_{43}$); a radical bearing exactly the same relation to the lauryl that the methyl does to the acetyl in acetone.

Lauric acid, laurostearic acid, or *pichurinstearic acid* ($C_{24}H_{48}O_4 = C_{24}H_{43}O_2 \left\{ \begin{smallmatrix} O_2 \\ H \end{smallmatrix} \right\} O_2$), was first obtained from the fixed oil of bay-berries (*Laurus nobilis*), hence the name. It is also contained in the solid fat of sassafras nuts or pichurin beans [NECTANDRA, *Puchury minor*, in NAT. HIST. DIV.], in cocoa-nut oil, and in cacao butter. By saponification with potash these fatty matters yield laurate of potash, from which the lauric acid may be separated by tartaric acid, gentle application of heat causing the bitartrate of potash to subside and the melted lauric acid to float on the surface.

Lauric acid is, at ordinary temperatures, a transparent crystalline mass. It is very soluble in alcohol or ether, the solution possessing a strongly acid re-action. By careful manipulation it may be obtained in silky needles. Its specific gravity is 0.883; melting point between 108° and 110° Fahr.

Laurostearin is a combination of lauric acid and glycerin, forming the natural fats already mentioned. When purified by repeated crystallisation from boiling alcohol it forms a mass of white, brilliant, acicular crystals. Melting point about 112° Fahr.

Laurates have the general formula ($C_{24}H_{43}MO_4$); they are uncrystallisable.

Laurin is a substance crystallising in prisms on evaporating the alcoholic mother liquors from the preparation of laurostearin. It differs from the latter body in being very soluble in cold alcohol. Its composition is said to be $C_{44}H_{80}O_6$.

LAVANDULA. The medical uses of the products of various species are given under this head in the NAT. HIST. DIV.

LAW. In treating of the word *law* we will first explain its etymology, and the etymology of the equivalent words in the principal languages of the civilised world; we will next determine the strict and primary meaning of law, together with its various secondary meanings; we will afterwards state the most important species of law, in the strict sense of the word; and finally, we will make a few remarks on the origin and end of law.

1. *Etymology of Law, and the equivalent words in other languages.*—In the Greek language the most ancient word for law is *thémis* (*θέμις*, which contains the same root as *τίθημι*), meaning "that which is established or laid down." The common Greek word for law, after the Homeric period, is *νόμος*, which first occurs in the 'Works and Days' of Hesiod (v. 274-386, Gaisford), and contains the same root as *νέμω*, to allot or distribute. The only word which the Greek language possessed to signify a legal right was *dikaion*, or *dikaíωμα*. (See Hugo, 'Geschichte des Römischen Rechts,' p. 962, ed. xi.)

Jurisprudence was never cultivated as a science by the Greeks before the loss of their independence. Many causes concurred to prevent the Greeks from adding jurisprudence to the numerous subjects which they first subjected to a scientific treatment. The chief of these causes was perhaps the generally arbitrary character of the Greek tribunals, both in the democratic and oligarchical states. The Lacedæmonians had no written laws (see Aristotle's account of the jurisdiction of the Ephors in 'Polit.,' ii. 9; compare Müller's 'Dorians,' b. iii., ch. 6, s. 2; ch. 11, s. 2; and see Justinian's 'Institutes,' lib. i., tit. 2, s. 10), and they were besides too great contemnners of learning and science to cultivate law in a systematic manner. The Athenians possessed a considerable body of written laws, and, with their extraordinary talent both for speculation and action, they would probably have contributed something towards reducing law to a science, if the large numbers of the judges (*dikastrai*) in their courts had not led to a popular and rhetorical treatment of the questions which came before them, and, by diminishing the sense of personal responsibility, facilitated arbitrary decisions. (Xen., 'Mem.' iv. 4, 4.)

For the first scientific cultivation of law the world is indebted to the Romans. "How far our ancestors," says Cicero, "excelled other nations in wisdom, will be easily perceived on comparing our laws with the works of their Lycurgus, Draco, and Solon; for it is incredible how rude and almost ridiculous every system of law is, except that of Rome." ('De Orat.,' i. 44.) Apart from the general ability of the Romans in the business of civil and military government, the systematic cultivation of law in Rome is perhaps owing chiefly to the fact that the Roman tribunals were composed of a single judge, or magistratus. (Hugo, *Ibid.*, p. 345.) The persons filling the offices of *prætor urbanus* and *prætor peregrinus* (the magistrates who ultimately exercised the chief civil jurisdiction) were changed annually; and it was found convenient that every new prætor should, on his accession to his office, publish an authentic statement of the rules which he intended to

observe in administering justice. In process of time these rules, known by the name of the *prætor's edict*, were handed down, with little alteration, from one prætor to another; and they furnish a text for the commentaries of the Roman lawyers, many of whose expository writings were drawn up in the form of treatises *ad edictum*.

The scientific cultivation of law among the Romans naturally led to the formation of a technical legal vocabulary in their language. The Latin is accordingly very rich in legal terms, many or most of which have been retained in the modern languages of western Europe, especially in those countries whose legal systems are founded on the Roman law. The only terms, however, with which we are at present concerned are those which denote the most general notions belonging to the subject of jurisprudence. *Lex*, which has the same etymological relation to *lego* that *rex* has to *rego*, meant properly a measure proposed by a magistrate in the *comitia*, or assembly of the people. A *lex* was not necessarily a rule, and might relate to a special case (Hugo, *Ibid.*, p. 327); but as most of the *leges* proposed by the magistrates were general, the word came to signify a written law. *Jus* denoted law generally, whether written or unwritten; it also denoted a legal right or faculty. *Lex* signified "a law;" *jus* "law" generally. (Austin's 'Province of Jurisprudence,' p. 307.)

The Romance languages have retained the word *lex* in the Latin acceptation (*legge* Italian, *ley* Spanish, *loi* French). They have however lost the word *jus* (though they retain many of its derivatives), and have substituted for it words formed from the passive participle of *dirigo* (*diritto* Italian, *derecho* Spanish, *droit* French), probably after the analogy of the German *recht*.

Nearly all the Teutonic languages (including the Anglo-Saxon) possess some form of the word *recht*, with a double sense equivalent to the Latin *jus*, namely, *law* and *faculty*. The modern English uses *right* in the sense of *faculty* alone. The High German has *gesetz* (from *setzen*, "to place," like *θεσμός* and *θέμις*), for a written law equivalent to *lex*. The Low German languages have, instead of *gesetz*, a word formed from *legen*, to lay down, which in Anglo-Saxon is *laga* or *lag*, in modern English *law*. The word *law*, however, in modern English, has not the limited sense of *gesetz*, but is coextensive with the Latin *jus*, when the latter does not signify *faculty*. We do not wish to dwell unnecessarily on these etymologies, but we will shortly notice that, besides *regt*, the Dutch language has the word *wet* in the sense of *law*. This word is derived from the ancient *withan*, Gothic, "to bind," and is equivalent etymologically to the Latin *obligatio*. The English verb *to wed* is the same word. *Ehe*, which signifies *marriage* in modern German, originally meant *law* or *ordinance* ('Nibelungen Lied,' v. 139, 5061); so that the Dutch *wet* and the English *wed* stand to one another in the same relation as the ancient and modern senses of *ehe*.

2. *Proper and improper Meanings of the word Law.*—A *law*, in the strict sense of the word, is a general command of an intelligent being to another intelligent being.* Laws established by the sovereign government of an independent civil society are styled *positive*, as existing by *positio*. [SOVEREIGNTY.] When law is spoken of simply and absolutely, *positive* law is always understood. Thus in such phrases as "a lawyer," "a student of law," "legal," "legality," "legislation," "legislator," &c., *positive* law is meant. *Positive* law is the subject-matter of the science of jurisprudence. [JURISPRUDENCE.] Every general command of a sovereign government to its subjects, however conveyed, falls under the head of *positive* laws. The general commands of God to man (whether revealed or unrevealed) are called the laws of God, or the Divine law: they are sometimes also known by the name of "natural law," or "law of nature." The Divine law (according to the phraseology just explained) is the standard to which all human laws ought to conform. On the mode of determining this standard some remarks will be made lower down.

Besides *positive* law, which is known to be a command enforced by a sanction,† and the Divine law, which is presumed to be so, there are some classes of laws which are not commands, though they bear an analogy, more or less remote, to laws properly so called. Thus by the term "law of nations," or "international law," are signified those maxims or rules which independent political societies observe, or ought to observe, in their conduct towards one another. An independent political society is a society which is not in the habit of rendering obedience to a political superior; consequently, an independent political society cannot receive a command or be subject to a law properly so called. But inasmuch as the maxims of international morality are general, and determine men's wills by the fear of provoking the hostility of other independent societies against their own country, there is a close analogy between the so-called "law of nations" and *positive* law.

Other classes of laws not imperative, but having as close an analogy to laws proper as the maxims composing international law, are the "law of honour" and the "law of fashion;" the laws of certain sports

* "Lex nil aliud quam *regula imperans*," says Bacon, 'De Augm. Scient. lib. viii., aph. 83. The word *regula*, or *rule*, is ambiguous: it sometimes signifies a *norma*, maxim, or canon simply; it sometimes signifies a *norma*, maxim, or canon, accompanied with a command. Moreover, it is a metaphor to say that the rule or *norma* itself commands. Bacon's definition would therefore be more precise if expressed as follows:—"Lex est *norma summi imperantis*."

† A sanction is the evil with which any one is visited in consequence of disobedience to a command.

and games also stand in a similar predicament. The term *law* is also employed in certain cases where the analogy to laws properly so called is much more remote. Instances of this usage are such expressions as the "laws of motion," the "law of attraction or gravitation," the "law of mortality" in a given country, the "law of population," the "laws of human thought," the "law of a mathematical series." In laws of this class (which may be styled "metaphorical laws") there is no command and no intelligence to work upon; nothing more is signified than that there is a certain uniformity of phenomena, analogous to the uniformity of conduct produced in men by the operation of a law properly so called. [ANALOGY.]

3. *Species of Positive Law.*—The *positive* laws of any country, considered as a system, may be divided with reference to their *sources* (or the modes by which they become laws) into *written* and *unwritten*. This division of laws is of great antiquity; the expression *unwritten laws* occurs in Xenophon's 'Memorabilia,' in a conversation attributed to Socrates (iv. 4, 19), in the 'Antigone' of Sophocles (v. 450-7, comp. 'Aristot. Rhet.' i. 13, 2), in the 'Republic and Laws of Plato' (v. 563 and 793, ed. Steph.), and in Demosthenes ('Aristocrat,' p. 639, ed. Reisk). In these passages it appears to signify those rules of law or morality which (being founded on obvious dictates of utility) are nearly common to all countries. Unwritten law, in this sense, corresponds with the *jus naturale* of the Roman lawyers. In the language of the Digests and the Institutes, the terms *written* and *unwritten law* ("jus quod constat ex scripto aut ex non scripto") are used in a more precise manner, to signify those laws which had been promulgated by the Roman legislature in writing, and those rules of law which had been tacitly adopted by the same legislature from usage.* For (as it is stated in a passage of the Digests) "since the laws derive their binding force from nothing but the decision of the people, it is fitting that those rules which the people have approved of without reducing them to writing should be equally obligatory. For what difference is there whether the people declares its will by vote, or by its conduct?" (Dig. i. 3. 32.)

Sir William Blackstone, dividing the law of England into "the *lex non scripta*, the unwritten or common law, and the *lex scripta*, the written or statute law," goes at some length into the explanation of unwritten law generally, and the elements of which it is composed, as well as into a specific account of the matter composing the unwritten law of England. (1 Com. p. 63.)

In that passage Blackstone clearly explains that unwritten law is so called, not because it does not exist in writing, but because it was not promulgated by the legislature in a written form. His statement of the sorts of laws severally comprehended by the classes of written and unwritten law in England is erroneous. Written law comprehends not only the statutes made by the parliament or supreme legislature, but also the written regulations issued by subordinate legislatures, as orders in council, and rules of court made by the judges. Unwritten law, moreover, comprehends not only the common law which is administered by the courts styled 'courts of common law,' but also the greatest part of the law styled 'equity,' which is administered by the courts styled 'courts of equity.'

Unwritten law has been called by Mr. Bentham *judge-made law*; a name which correctly denotes the mode by which it becomes law.

It may be remarked that a written law is called a law, but that a rule of unwritten law is never called a law. This phraseology corresponds to the distinction between *lex* and *jus*, and *gesetz* and *recht*, which was explained above.

Positive laws are also divided, according to their *source*, into laws made by *supreme*, and laws made by *subordinate* legislatures. In other words, laws may be issued by the sovereign legislature, or by functionaries deriving their authority from the sovereign legislature.

The *sources* of law are not unfrequently confounded with its *causes*; in other words, with the facts which induce the sovereign to invest certain maxims with the legal sanction. Thus it is fancied that a rule of customary or consuetudinary law exists as law, by virtue of custom or usage, and not by virtue of the authority of the sovereign or his representative, who has imparted to it a binding force. This subject is clearly explained in Mr. Austin's 'Outline of a Course of Lectures on General Jurisprudence,' pp. 10, 11.

The laws of a state, considered as a system, may be divided, with reference to their *subject-matter*, into *public* and *private*. The division of *jus* into *jus publicum* and *jus privatum* originated with the Roman jurists, and occupies a conspicuous station at the beginning of the Digests and Institutes. No trace of this division exists, as far as we are aware, in any Greek author. *Jus publicum* is defined to be 'quod ad statum rei Romanæ spectat,' 'quod in sacris, in sacerdotibus in magistratibus consistit.' *Jus privatum* is that 'quod ad singulorum utilitatem pertinet.' The institutional treatises of the Roman lawyers appear to have been confined to *jus privatum*; the Institutes of Justinian do not touch upon *jus publicum*, except in the final chapter *De Publicis Judiciis*, and this chapter is wanting in the Commentaries

* The distinction of law into written and unwritten does not seem to have been regularly made by the Roman jurists; for it does not occur in Gaius, from whose Commentaries the substance of the second title of the first book of the Institutes is borrowed. The distinction in question is introduced, both in the Digests and the Institutes with a reference to the Greek writers, doubtless philosophers.

of Gaius on which the Institutes of Justinian are mainly founded. Hence it appears that the Roman lawyers included under *jus publicum* not only the powers of the sovereign, and the rights and duties of persons in public conditions but also criminal law. Their definition of *jus publicum*, however, does not properly include criminal law, and the term, as used by later writers, has not in general this extension. *Publicus* is the adjective of *populus*, and signifies that which belonged to the sovereign body of the citizens; hence *jus publicum* signified that law which concerned the government of Rome, and its magistrates and other functionaries. *Privatus* seems to have meant originally that which was separated or set apart from any common stock; hence it came to signify that which did not concern directly the public or state.

The formal division of law into public and private is not to be found in the institutional treatises of English law. It is, however, used by Lord Bacon, in his treatise 'De Augmentis,' lib. viii., aph. 80; where he advises that after the model of the Roman jurists, *jus publicum* should be excluded from institutional treatises.

Sir W. Blackstone, in the first book of his 'Commentaries,' treats of the rights and duties of persons, in their public and private relations to each other (pp. 146, 422). The former branch of this division, which occupies chapters 2 to 13, comprehends *jus publicum*, in its limited sense, which nearly corresponds to the English term 'constitutional law.' The *droit politique* or *constitutionnel* of Mr. Bentham, in his 'Traité de Legislation' (tom. i., p. 147, 325-6, ed. 1802), is also equivalent to *jus publicum*, in its strict sense. (Austin's *Outline*, p. lxvii.)

Positive law is further divided, with reference to its subject, into the law of persons and the law of things. The Roman jurists, who were the authors of this division, arranged these two classes under the head of *jus privatum*, together with a third, viz., the law of actions, or of judicial procedure. A full explanation of this important division is not consistent with the purpose of the present article: a brief and lucid statement will be found in Mr. Austin's 'Outline' already cited, pp. xvi-xviii. The most important conditions or *status*, composing the law of persons, are *public* or *political*, and *private*. The former species includes all persons sharing the sovereign power and all public functionaries; the latter includes the conditions of husband and wife, parent and child, master and servant, guardian and ward, &c. The term *jus publicum*, when used in a precise sense, is equivalent to the former of these species. Sir W. Blackstone, misled by the ambiguity of the Latin word *jus*, has rendered *jus personarum* and *jus rerum* by 'rights of persons,' and 'rights of things.' The origin of this portentous blunder is explained in Mr. Austin's 'Outline,' p. lxiii.

Positive law is also divided, with reference to the legal consequences of a breach of legal duty, into *civil* and *criminal*.

Civil law is that department of law in which every breach of a duty may be made the subject of a legal proceeding, for the purpose of conferring on the person wronged a right from the enjoyment of which he is excluded by the defendant, or of obtaining from the defendant compensation for a right violated by him. *Criminal law* is that department of law in which every breach of duty may be made the subject of a legal proceeding instituted by the sovereign or his representatives, for the purpose of inflicting punishment on the person charged with the breach of duty. The scope of a civil action is the redress of the plaintiff, by conferring on him the right, or compensation for the violation of a right, which he claims from the defendant. The scope of a criminal prosecution is to inflict punishment on the defendant for the breach of a legal duty which is imputed to him. *Penal law* is not identical with *criminal law*; for an act or omission may be liable to legal punishment in consequence of an action instituted by a *private person*. The action in English law termed a *qui tam* action is partly a civil and partly a penal, but is in no respect a criminal action. By the *civil law*, in England, is commonly understood the Roman law generally, or that portion of it which is received in the ecclesiastical courts.

Law is sometimes opposed to *equity*. *Equity*, in this sense, implies an arbitrary or discretionary power in the tribunal to decide, not according to prescribed rules of law, but according to its own conceptions of moral justice. In the language of the English law, *common law* is opposed to *equity*, concerning which opposition see EQUITY. *Common law* is so denominated as being founded on usages common to the whole nation, and not peculiar to a certain district. (1 Blackst. 'Comm.' p. 67-8.) In like manner, "the Book of Common Prayer" is so designated in order to distinguish it from forms of prayer intended for *private* devotion. It may be remarked, that, in the language of the Roman law, *jus civile* is opposed to *jus prætorium* (the law made by the judicial legislation of the prætors), in the same manner that, in the language of the English law, *common law* is opposed to *equity*.

A *law* is likewise opposed to a *privilegium*. *Privilegium* is an ancient term of the Roman law, inasmuch as it occurred in the Twelve Tables. (Cicero, 'Leg.' iii. 19.) It signified, according to its etymology, a measure directed at a single person (*hominem privum*), as distinguished from a law which applies to *classes* of persons; for it is stated in a fragment of Ulpian preserved in the Digests, "jura non in singulas personas, sed generaliter constituuntur." (D. i. 3. 8.) The latter part of the word *privilegium* is connected with *lex*; but we have

already stated that *lex* originally did not necessarily signify a rule. More properly, however, a *privilegium* signifies a special command of the sovereign, not founded on an existing general command or law. Such a *privilegium* may either be beneficial to the person or persons affected by it, as an exemption from all personal actions which the king of England can (or could) grant by his *writ of protection* (Blackst. 3 'Com.,' p. 289); or it may deprive him of some of his rights, or inflict some punishment upon him. The difference between a law and a *privilegium* is explained by Sir W. Blackstone as follows:—"Municipal (that is, positive) law is a rule; not a transient sudden order from a superior to or concerning a particular person, but something permanent, uniform, and universal. Therefore a particular act of the legislature to confiscate the goods of Titius, or to attain him of high treason, does not enter into the idea of a municipal law; for the operation of this act is spent upon Titius only, and has no relation to the community in general; it is rather a sentence than a law. But an act to declare the crime of which Titius is accused shall be deemed high treason; this has permanency, uniformity, and universality, and therefore is properly a rule" (or law). (1 'Com.,' p. 44.) The distinction here adverted to is that meant by the Greek writers when they speak of governments administered according to law, and governments administered not according to law. (See particularly Aristotle, 'Polit.,' iv., 4, 5.) In the latter class of states, the acts of the government were a succession of *privilegia* (generally styled by the Greeks *ψηφίσματα*, although *ψηφίσματα* were often laws, strictly so called). Montesquieu's distinction between monarchy and despotism is founded upon the same principle. ('Esprit des Lois,' ii. 1.) Government by *privilegia* is properly called *arbitrary* government, the government being administered not according to rules, but according to the *arbitrium* of the sovereign one or many.

Concerning the difference between the making of laws and the execution of them, or (as they are termed) the *legislative* and *executive* functions of government, see LEGISLATION.

Law is sometimes opposed to *fact*; that is to say, the rule of law is distinguished from the facts or events to which it is applied in practice. In this sense it is said that every one is presumed to know the law; whereas ignorance of the fact is an excuse. (For the doctrines of the Roman law on this subject, see 'Dig.' 22. 6.) The distinction between law and fact is important in our system of jurisprudence, with reference to trial by jury; for, according to the theory of our law, the judge decides concerning the law, and the jury concerning the fact. This maxim is, however, little more than theory; for in practice the jury, by its power of returning a general verdict, is judge both of the law and the fact. [JURY.] (See Best on 'Evidence,' 3rd edit. p. 103.)

Laws, considered singly, have been divided into numerous species, as declaratory, remedial, penal, repealing, &c., laws. Concerning these see Austin's 'Province of Jurisprudence,' p. 22, and Dwaris on 'Statutes,' ch. 10.

4. *Origin and End of Positive Law.*—It has been above stated that all positive laws are commands, direct or indirect, of the person or persons exercising supreme political power in an independent society. Consequently the notion that positive laws are derived from a compact between sovereign and subjects (styled the *original* or *social contract*) is a delusion.

The proper end of positive law is the promotion of the temporal happiness, or well being, of the community over which the law extends. Thus Aristotle, in his 'Politics,' says that "political society was formed in order to enable men to live, and it continues to exist in order that they may live happily." (l. 2.) "Finis et scopus (says Lord Bacon) quem leges intueri atque ad quem jussiones et sanctiones suas dirigere debent, non alius est quam ut cives feliciter degant." ('De Augm.,' lib. viii., aph. 5) The meaning of Aristotle and Bacon, in the passages just cited, was no other than that expressed by Mr. Bentham in his well-known formula, that the end of political government is "the greatest happiness of the greatest number."

We have stated that the proper end of positive law is the promotion of the temporal happiness of the community. The end of the political union is the promotion of the happiness of its members in the present state of existence; that is to say, in the existence which is comprehended between birth and death. The promotion of men's happiness in the existence which commences after death is the end of the religious or ecclesiastical union. (See Warburton's 'Divine Legation,' b. 1, s. 2, vol. i., p. 215, 8vo ed.)

From the benevolence of the Deity, it is presumed that those rules which tend the most to produce the happiness of his creatures are most agreeable to him; and consequently the term "Divine law" (also called natural law) is used to signify those maxims to which human laws ought to conform. In the vast countries where the Mohammedan and Brahminical religions prevail, a great proportion of the positive law is supposed to be derived from the direct revelation of a supernatural being; and therefore the Divine law and the positive laws of the state in great measure coincide. The Christian dispensation, however, does not (like the Jewish) contain any system of rules out of which a body of positive law can be formed, or which can be enforced by a civil government. Consequently, in Christian countries a very small part of positive law is founded upon precepts derived from immediate revelation: the far greater part of positive law is or ought to be fashioned

upon rules of Divine law, which are only discoverable by a process of inference from the phenomena of human society.

LAW, CRIMINAL. The object of the English, as of every other system of criminal law is the prevention of injuries by the terror of punishment. But it is not every injury the commission of which the law thinks fit to prevent by such means; in most cases it is satisfied with the redress of injuries after they have been committed, by either restoring the party injured to his right, where that is possible, or by giving him compensation in damages. In law, an injury is any violation of a legal right or omission of a legal duty: a crime, then, may be defined to be such a violation of a legal right or omission of a legal duty as subjects the person guilty of it to punishment. Such acts or omissions for which the law affords redress only have, in England, been usually denominated civil injuries as contradistinguished from crimes. It is to be observed, however, that, in strictness, every crime includes an injury, in respect of which some individual or the public may be entitled to redress. In felony, indeed, such injury is said to be merged in the crime; but this doctrine appears to have originated in the circumstance of all felonies having, with one or two exceptions, been originally punishable with death and having worked a forfeiture of all the offender's property, and so rendered redress impossible.

Crimes, according to the English law, are divisible into two great classes, which depend upon the mode of proceeding peculiar to each, namely, into—

1. Such as are punishable on indictment or information (the common law methods of proceeding).

2. Such as are punishable on summary conviction before a justice or justices of the peace or other authorised persons, without the intervention of a jury (a mode of proceeding derived entirely from special statutory enactments).

It is proposed, in the first place, to treat of offences punishable on indictment or information, and afterwards to shortly refer to those punishable on summary conviction.

Offences punishable on Indictment or Information.

Indictable offences are distributable into four classes or divisions—namely, treasons, *præmunires*, felonies, and misdemeanors. Persons who commit the offences which constitute the last-mentioned division may also be prosecuted by criminal information instead of being indicted.

The distinction between these classes is for the most part a merely arbitrary one, without any apparent reference to rule or principle, the consequence of which is, that offences in their nature wholly undistinguishable are, in many instances, separated and subjected to punishments widely disproportionate, and to forms of procedure widely dissimilar. In fact, the only real distinguishing feature between one class of crimes and another, at the present day, is to be found in certain peculiarities of punishment and procedure incident to each. Formerly, however, the classes of crimes were marked by distinctive characteristics; but they have subsequently, either by artificial constructions of the courts or by legislative enactments, been made to embrace offences of a very different nature from those originally included within them. For instance, the crime of treason, whether high or petit, implied a violation of the allegiance due from an inferior to a superior. In the case of high treason, so called "by way of eminent distinction," it was the violation of the allegiance due from a subject to his liege lord and sovereign; and in case of petit treason, which was limited to the murder of a husband by his wife, a master by his servant, or an ecclesiastic by his inferior who owed him faith and obedience, it was the breach of the allegiance of private and domestic faith.*

The characteristic above pointed out can no longer be traced in many of the various constructive treasons which have been from time to time created by the courts. It will be sufficient here to give a single illustration of the mode in which the law of treason has been stretched to reach cases totally inconsistent with its original design. By one of the clauses of the statute of treasons (25 Edw. III. c. 2) it is declared to be treason to *levy war against the king*. A riotous assembly attempting by force to redress a public grievance—as, for example, to pull down *all* inclosures or to burn *all* meeting-houses—has been held to be a *levying of war* within the meaning of this clause, although there has been no direct intention or design whatever against either the state or the person of the king. This construction is said to depend upon the *generality* of the design. If the intention be to pull down *particular* inclosures or meeting-houses only, the offence is a mere riot, and in quality a simple misdemeanor. Although the generality of the design may be a reason for awarding a higher punishment in the former than in the latter case, there appears to be no foundation in reason or principle for construing an offence, which but for such generality would be a misdemeanor only, to amount to the crime of treason in levying war against the king.

Again, the term "*præmunire*" was originally applied to offences which consisted in the introduction of any foreign jurisdiction, more especially the authority of the see of Rome, into the kingdom, but has subsequently, to use the language of Mr. Serjeant Hawkins ('*Pleas of*

* Petit Treason was abolished by the 9 Geo. IV. c. 31, s. 2, and the offences constituting it declared to be murder only.

the Crown,' b. 1, c. 19), "been applied to other heinous crimes, for the most part having relation to the offences originally coming under the notion of *præmunire*, but in some instances none at all." The Habeas Corpus Act (31 Car. II. c. 12) contains an instance of the latter mode of application. By the 12th section of that Act it is made a *præmunire* to send any inhabitant of England, Wales, or the town of Berwick-upon-Tweed, a prisoner beyond the seas in defiance of its provisions to the contrary.

The term "*præmunire*" was adopted from the first word of the original writ on which the subsequent proceedings were founded: "*Præmunire* (for *præmoneri*) *facias* A. B. quod sit coram nobis," &c. [*PRÆMUNIRE*.] The Criminal Law Commissioners proposed to abolish *præmunires* as a class of crimes. (Seventh Report.)

The crime of felony had its origin in very remote times, and was founded upon feudal principles. Its incidents were not formerly, as they are now, of a mere arbitrary nature, peremptorily annexed to certain criminal acts without reference to rule or principle. The crime originally consisted in a violation of the feudal contract by the misconduct of the lord or of the tenant; and where committed by the tenant, occasioned as a consequence the forfeiture of his feud to the lord. (4 Black. 'Comm.,' p. 96; 4th and 7th 'Repts. of Crim. Law Commrs.')

Those crimes, therefore, which induced such forfeiture, and, by a small deflection from the original sense, those which induced the forfeiture of goods also, were denominated felonies; and afterwards, by long use the term *felony* came to signify the actual crime itself, and not the penal consequence. "So that upon the whole," to use the words of Mr. Justice Blackstone (4 'Comm.,' p. 95), "the only adequate definition of felony seems to be that which is before laid down, namely, an offence which occasions a total forfeiture of either lands or goods, or both, at the common law; and to which capital or other punishment may be superadded according to the degree of guilt." Where the punishment is less than capital, the offender loses his goods only; where capital, his lands as well as his goods. The crimes which occasioned such forfeiture were originally, with one or two exceptions, capital; but at the present day there are offences for which no greater punishment can be inflicted than imprisonment for a term not exceeding three years, which are felonies, and consequently occasion the forfeiture of all the offender's goods and chattels; whilst other crimes, for which the punishment may be as high as penal servitude, are misdemeanors only, and work no forfeiture. It is apparent from this that the present law is very defective, and that the amount of punishment is no longer the test of distinction between a felony and misdemeanor. It was proposed by the Criminal Law Commissioners ('Seventh Rep.' p. 16) to remedy this by making the liability to transportation the test of distinction, that is, that all offences liable to a less punishment than transportation should be misdemeanors only.

The term "*Misdemeanor*" is used in the English system of Criminal Law to denote such indictable offences are of a lower degree than felony.

We shall now point out the peculiarities of punishment which distinguish one class of crimes from another at the present day. In order to this, the penal consequences incident to the whole body of offences constituting each class will be first stated, and then in what respects those consequences differ from each other. The classes will be taken in the same order as above.

Treasons.—Treasons, with one exception mentioned below, are capital; but whether capital or not, the offender, *upon conviction*, forfeits to the crown the personal estate of every description, whether in action or possession, or settled by way of trust, which the offender has otherwise than as an executor ('Cro. Car.' 566), or a trustee, or a mortgagee (13 & 14 Vict. c. 60.) at the time of conviction; and in the case of capital treasons, *upon attainder by judgment of death or outlawry*, the blood of the offender is corrupted, but not so as to obstruct descents to such offender's posterity, when they are obliged to derive a title through such offender to a remoter ancestor (3 & 4 Will. IV. c. 105, s. 10), and all the freehold lands and tenements of inheritance in fee-simple or fee-tail, and all other hereditaments (except copyholds), whether in possession, reversion, or remainder; and all the rights of entry on freehold lands and tenements which the offender has (otherwise than as a trustee or mortgagee, at the time of the offence committed or at any time afterwards), and also the profits of all freehold lands and tenements which the offender has in his or her own right for life, so long as such interest shall subsist, and, if the offender be a male, his wife's dower, are forfeited to the crown (4 Black. 'Comm.,' 381; 26 Hen. VIII. c. 13, s. 5; 33 Hen. VIII. c. 20, s. 2; and 5 & 6 Edw. VI. c. 11, ss. 9 & 13); and all the copyhold estates belonging to the offender at the time of the offence committed are forfeited to the lord of the manor ('Com. Dig.' Copyhold (M) I.). The above penal consequences are general to all capital treasons, unless, as is sometimes the case, the act which creates the particular treason expressly exempts from some of them. The before-mentioned non-capital treason renders the party guilty of it liable to those only of the above consequences which accrue upon conviction, since the others follow only upon the party's being attainted, that is, sentenced to death or outlawed, which latter, in the case of capital treasons and felonies, is of the same effect as being sentenced to death. The existence of this non-capital treason would appear to be the result of inadvertence. By the Forgery Con-

solidation Act (11 Geo. IV. & 1 Will. IV. c. 66) it was declared to be treason and punishable with death to forge the great and other royal seals and the sign manual. By the 2 & 3 Will. IV. c. 123, the punishment of death was repealed for forgery in all but the two cases of wills and powers of attorney to transfer stock (it has been since taken away in these cases also by the 7 Will. IV. & 1 Vict. c. 84); but the *quality* of the offences enumerated in the Forgery Consolidation Act was left without alteration; so that to forge the royal seals, &c, would appear to be still treason, though no longer a capital offence.

The judgment of death in the case of treason is that the offender, if a male, be drawn on a hurdle to the place of execution, and be there hanged by the neck until dead; and that afterwards the head be severed from the body of such offender, and the body be divided into four quarters, to be disposed of as her Majesty shall think fit (54 Geo. III. c. 146); and, if a female, that the offender be drawn to the place of execution and be there hanged by the neck until dead (30 Geo. III. c. 48, s. 1). The queen, however, may, by warrant under her sign manual, countersigned by a principal secretary of state, direct, where the offender is a male, that he shall not be drawn, but taken in such manner as in the warrant shall be expressed to the place of execution, and that he shall not be hanged, but be beheaded, whilst alive, instead (54 Geo. III. c. 146, s. 2).

2. *Præmunires*.—The penalties of præmunire, as shortly summed up by Sir Edward Coke (1 'Inst.' 130 a.), are, "that from the conviction the defendant shall be out of the king's protection, and his lands and tenements" (that is, in fee-simple or for life, but not in tail beyond his life interest therein), "goods and chattels, forfeited to the king: and that his body shall remain in prison at the king's pleasure, or, as other authorities have it, during life." These penalties were first imposed by the stat. 16 Rich. II. c. 5 (commonly called the Statute of Præmunire); and it is by reference to that statute that all subsequent præmunires have been made punishable. It was formerly supposed that a person convicted of præmunire, being put out of the king's protection, might be killed with impunity, as being the king's enemy; but by the 5 Eliz. c. 1, ss. 21 and 22, it was enacted that it should not be lawful to kill any person attainted in a præmunire, saving such pains of death or other hurt or punishment as theretofore might, without danger of law, be done upon persons sending or bringing into the realm, &c., any process, &c., from the See of Rome. The statute of Elizabeth was, however, repealed by the 9 & 10 Vict. c. 59. Præmunires, although they occasion a forfeiture of the offender's lands and goods, are not felonies. To constitute a felony the offence must have worked a forfeiture at the common law; but in the case of præmunire the forfeiture is made a part of the punishment by statute merely, which is not sufficient. (4 Black. 'Comm.' pp. 94 and 118.)

3. *Felonies*.—All felonies, as stated above, were originally, with one or two exceptions, punishable with death; but the offender, unless the felony was excluded from the benefit of clergy, was entitled for a first offence, to be discharged from the capital punishment upon praying that benefit. [BENEFIT OF CLERGY.] But now, since the passing of the 7 & 8 Geo. IV. c. 28, no felony is punishable with death unless it was excluded from the benefit of clergy before or on the 14 Nov. 1826, or has been or shall be made punishable with death by some statute passed since that day. Where not capital, felonies are punishable either in the manner prescribed by the statute or statutes specially relating to such felonies, or, where no punishment has been or may hereafter be specially provided, with penal servitude for seven years, or imprisonment for any term not exceeding two years, with the addition, if the court shall think fit, of whipping, where the offender is a male, hard labour and solitary confinement, or any of them. (7 & 8 Geo. IV. c. 28, ss. 7 and 8.) Such confinement must not, however, be for a longer period than one month at a time, or three months in a year. (7 Wm. IV. & 1 Vict. c. 90, s. 5.) In the case of *all* felonies, whether capital or not, the offender immediately on conviction forfeits to the crown all the personal estate of every description, whether in action or possession, or settled by way of trust, which he has otherwise than as an executor ('Cro. Car.' 566), or a trustee or mortgagee (13 & 14 Vict. c. 60), at the time of conviction (Bac. 'Abrid.' "Forfeiture" (B); Co-Litt. 391 a); and in the case of all capital felonies, upon attainer by judgment of death or outlawry, forfeits to the crown the profits of all estates of freehold (4 Black. 'Comm.' 385), and of things not lying in tenure (Bac. 'Abrid.' "Forfeiture" (A)), and to the lord of the manor the profits of all estates of copyhold (Hawk. 'P. C.' b. 2, c. 49, s. 7; Lord Cornwallis's case, 2 Vent. 38-9), which the offender has, otherwise than as a trustee or mortgagee (13 & 14 Vict. c. 60), at the time of the offence committed, during his life; and his blood is corrupted (but not so as to obstruct descents to the posterity of such offender where they are obliged to derive a title through him to a remoter ancestor (3 & 4 Will. IV. c. 106, s. 10), and after his death his copyholds which he holds in fee-simple are forfeited to the lord of the manor. (Scriven 'On Copyholds,' 523, note (d).) And also in the case of murder, all his freehold lands and tenements in fee-simple escheat (subject to what is called the crown's year, day and waste) to the lord of the fee. (54 Geo. III. c. 145; Co-Litt. 391 a; 4 Black. 'Comm.' 385.) The Court of Chancery may appoint a new trustee in the place of a trustee convicted of felony, and may make an order vesting the estate in the new trustee. (15 & 16 Vict. c. 55, s. 8.)

The judgment of death in the case of all capital felonies, except

murder, is that the offender be hanged by the neck until dead (2 Hale's 'P. C.' 411); and, in the case of murder, it is the same, with the addition that the offender's body shall be buried within the precincts of the prison in which he shall have been confined after conviction. (2 & 3 Will. IV. c. 75, s. 16; 4 & 5 Will. IV. c. 26.) The court however is empowered, if it shall think that the offender is a fit subject to be recommended to the royal mercy, to abstain from pronouncing judgment of death upon him, and to order such judgment to be entered of record instead; and the judgment so recorded has the same effect as if pronounced and the party were reprieved. (4 Geo. IV. c. 48, ss. 1 and 2; 6 & 7 Will. IV. c. 30, s. 2.)*

The following felonies are still punishable with death:—

1. Destroying ships of war or her majesty's arsenals, dock-yards, naval, military or victualling stores, or other ammunition of war, &c. (12 Geo. III. c. 24, s. 1.)
2. Murder. (9 Geo. IV. c. 31, s. 3.)
3. Unnatural offences. (9 Geo. IV. c. 31, s. 15.)
4. Attempts to murder by administering poison, or by wounding, or by any other means where bodily injury dangerous to life is caused. (7 Wm. IV. & 1 Vict. c. 85, s. 2.)
5. Burglary, aggravated by striking an inmate. (7 Wm. IV. & 1 Vict. c. 86, s. 2.)
6. Robbery, aggravated by wounding the person robbed. (7 Wm. IV. & 1 Vict. c. 87, s. 2.)
7. Piracy, aggravated by endangering the life of any person on board of the vessel in respect of which the piracy is committed. (7 Wm. IV. & 1 Vict. c. 88, s. 4.)
8. Setting fire to a dwelling-house, any person being therein. (7 Wm. IV. & 1 Vict. c. 89, s. 2.)
9. Destroying vessels with intent to murder, or whereby human life is endangered. (7 Wm. IV. & 1 Vict. c. 89, s. 4.)
10. Exhibiting false lights, &c. with intent to bring ships into danger, or unlawfully doing anything tending to the destruction of ships in distress. (7 Wm. IV. & 1 Vict. c. 89, s. 5.)

Besides the above offences, that of wilfully and without lawful excuse having or being possessed of any forged stamp used in pursuance of any Act relating to any duties on gold or silver plate made or wrought in Great Britain, for the purpose of marking or stamping such plate, appears to be still punishable with death.

That offence is contained in 55 Geo. III. c. 185, s. 7, by virtue of which enactment it was formerly also a capital crime to forge or utter the stamps provided for marking any such plate, or to fraudulently remove such stamps from one piece of such plate to another, or privately and secretly to use such stamps with intent to defraud the king. The punishment of death for these last-mentioned offences was repealed, however, by 11 Geo. IV. & 1 Wm. IV. c. 66, s. 1 (as to the forging and uttering), and by 4 & 5 Vict. c. 56, s. 1 (as to the removing and fraudulently using); but by some inadvertence (for it is clear that it can never have been intended) the offence of being possessed, without lawful excuse, of forged stamps for marking gold or silver plate (the least criminal of all the acts specified in 55 Geo. III. c. 185, s. 7) is still left capital.

There are two other enactments of capital offences, which also do not appear to have been repealed. The 2 Geo. II. c. 25, s. 2, and the 12 Geo. III. c. 48, s. 1, make it capital for offenders convicted under the provisions of those statutes, to escape or break out of prison; and these enactments do not seem to have been wholly repealed, either expressly or by implication. The Criminal Law Commissioners (7th Report) say, "Although many Acts have been passed which punish prison-breach by penalties not capital, yet these seem to be confined to particular gaols and prisons, and not to affect the general enactments above referred to, as regarding offenders against their provisions confined in other prisons."

4. *Misdemeanors*.—The punishment in the case of misdemeanors, where none is specially provided by statute, is generally fine and imprisonment. The statutable punishments vary from transportation for life (for which penal servitude has been substituted) to fine or imprisonment.

From what has been stated, it will be seen that the circumstance, so far as punishment is concerned, which distinguishes misdemeanors from all the other classes of offences, is the absence of forfeiture as a necessary consequence of conviction. The distinction between præmunires and felonies (which term, it should be remarked, in its largest sense, includes treasons, on account of the forfeiture which that class of crimes occasions) is, that the forfeiture which ensues upon a conviction of the former is, as before observed, in pursuance of statutable provisions; whereas in the latter case it is a common law consequence of the offence, and follows as a matter of course whenever a crime is declared to be a felony. There appears to be no distinction as regards punishment, independently of special statutable enactment, between non-capital felonies (the term is used here in its ordinary restricted sense) and the non-capital treason above described; but the difference between felonies and treasons when punishable with death is very

* See R. v. Hogg, 2 M. & Ro., 381, where it was held that since the passing of the 6 & 7 Will. IV. c. 30, death may be recorded in the case of murder as well as other capital felonies, notwithstanding the exception contained in the 4 Geo. IV. c. 48.

considerable. In the case of felonies the offender, upon attainder, forfeits to the crown the profits only of such freehold and copyhold lands as he had at the time of committing the offence, during his life, and after his death, his copyholds in fee-simple are forfeited to the lord of the manor; and even where attainted of murder, though his freehold estates in fee-simple fail after his death, it is not as a consequence of the law of forfeiture, but because they escheat for want of heirs capable of succeeding to them, owing to his blood being corrupted by the attainder; and it is on account of such estates escheating and not being forfeited that they go to the lord of the fee (that is, subject to the crown's year, day and waste), and not to the crown, unless there appears to be no intermediate lord between the offender and the crown, in which event the crown takes as ultimate lord of the fee. In the case of treason, however, the offender upon attainder, instead of forfeiting to the crown the profits merely of such freehold lands as he had at the time of committing the offence, during his life, forfeits all freehold estates of inheritance, as well those in fee-tail as those in fee-simple, and not only such as he had at the time of the commission of the offence, but those also which he may acquire at any time afterwards; and instead of forfeiting to the crown the profits of his copyholds during his life, and to the lord of the manor his copyholds in fee-simple only, he forfeits at once to the lord of the manor *all* the copyholds belonging to him at the time the offence was committed. Where the offender is a male, his wife's dower is also forfeited to the crown, which is not the case in felony. It is to be observed that the crown is empowered (see 59 Geo. III. c. 94) to restore the whole or any part of any lands or hereditaments to which it becomes entitled by escheat or forfeiture to the family of the offender, a provision which has greatly mitigated the harshness of the law of forfeiture. The Criminal Law Commissioners however recommended the entire abolition of the confiscation of property as a necessary incident to convictions for treason or felony ('Seventh Report on Criminal Law'). No forfeiture follows a summary conviction for felony under the Juvenile Offenders act (10 & 11 Vict. c. 82). The difference between the judgment of death for treason and that for felony requires no comment.

Besides the above peculiarities of punishment, these different classes of offences are distinguished by particular forms of procedure; but it will be more convenient to refer to these when describing our general system of criminal procedure.

According to the law of England, all persons above the age of seven years, except such as by reason of unripeness, weakness, unsoundness, disease, or delusion of mind, are incapable of discerning, at the time they do an act, that the act is contrary either to the law of God or the law of the land, are criminally responsible for such act; but temporary incapacity wilfully incurred by intoxication or other means is no excuse. An infant of the age of seven and under fourteen years, however, is to be presumed to be incapable of committing a crime until the contrary be proved. Duress, also, inducing a well-grounded fear of death or grievous bodily harm, will excuse a person acting under such duress in all cases except treason and murder; and a married woman committing any offence, except those last mentioned, if her husband be present at the time, shall be presumed to have acted under his coercion, and be entitled to an acquittal, unless it appears that she did not so act. A married woman also shall not be liable to conviction for receiving her husband or any other person in his presence and by his authority.

The whole of the law, written as well as unwritten, relating to the definition and punishment of offences, that is, the whole Criminal Law of England as regards indictable crimes and their punishments as it then existed, was collected and reduced into one body by the Criminal Law Commissioners (see their 7th Report), and was thus for the first time rendered accessible to the public at large. Before this reduction the Criminal Law had to be sought for in an immense mass of statutes, reported decisions, records, ancient and modern, and text-books; and, on that account, could be known but to the few, and those principally engaged in the practice or administration of the law. The digest so prepared by the Commissioners, and called by them 'The Act of Crimes and Punishments,' was comprised in twenty-four chapters, under the following heads:—

1. Preliminary Declarations and Enactments.
2. Treason and other offences against the State.
3. Offences against Religion and the Established Church.
4. Offences against the Executive Power generally.
5. Offences against the Administration of Justice.
6. Offences against the Public Peace.
7. Offences relating to the Coin, and to Bullion, and Gold and Silver Plate.
8. Offences relating to the Public Property, Revenue, and Funds.
9. Offences against the law of Marriage.
10. Offences relating to Public Records and Registers.
11. Offences against Public Morals and Decency.
12. Offences against Public health.
13. Common Nuisances.
14. Offences relating to Trade, Commerce, and Public Communication.
15. Homicide and other offences against the person.
16. Libel.

17. Offences against the Habitation.
18. Fraudulent Appropriations.
19. Piracy and Offences connected with the Slave Trade.
20. Malicious Injuries to Property.
21. Forgery and other offences connected therewith.
22. Illegal Solicitations, Conspiracies, Attempts, and Repetitions of Offences.

23. Definitions of Terms and Explanations.
24. Chapter of Penalties.

Upon the subject of punishments, the Commissioners recommended the abolition of forfeiture as an incident to convictions for treason or felony; were inclined to reject whipping as a mode of punishment, except in the case of discharging or aiming fire-arms, &c., at the queen (5 & 6 Vict. c. 51, s. 2), in which it has lately been imposed by the legislature as constituting a signal mark of ignominy; proposed that three, or at the utmost four, years should be the longest term of imprisonment to be inflicted for any offence, whether treason, felony, or misdemeanor, in cases where imprisonment forms the whole or part of the punishment; and suggested a scale of penalties, consisting of forty-five classes, to be substituted for the numerous punishments contained in the above statement. This scale might be much further reduced if the recommendations of the Commissioners should be adopted. At present it is extremely difficult in some instances to determine what punishment an offence is liable to.

A bill embodying the provisions of the 'Act of Crimes and Punishments,' subject to such omissions as were recommended by the Commissioners, was introduced, at the end of the session of 1844, in the House of Lords by Lord Brougham, but was ultimately withdrawn at the instance of the Lord Chancellor, who undertook to issue a commission for the purpose of revising it, that duty being too laborious for any government to grapple with, and if their report should be favourable to its adoption, to found one or more government measures upon it, as should be thought most expedient. A commission was accordingly appointed for this, amongst other purposes, 1845, but no practical result followed. The members of the old commission made a report containing a digest of the law of procedure as regards indictable offences (a most difficult and laborious undertaking).

Besides the 'Act of Crimes and Punishments,' and the Digest of the Law of Procedure, several other most important reports emanated from the original Criminal Law Commission. It was upon their recommendation that the Acts of the first year of her present Majesty's reign, repealing the punishment of death in the case of between thirty and forty crimes, were founded. It was a report of theirs which mainly contributed to the alteration of that harsh and inconsistent rule of our law which denied a prisoner his full defence by counsel upon a charge of felony. They also made a very elaborate and valuable report upon the Consolidation of the General Statute Law, and a report upon the subject of Juvenile Offenders—in all, the number of reports which issued from the commission between the period of its first appointment in 1823 and its termination in the year 1845 was eight.

A sum exceeding 65,000*l.* has been spent on various commissions, which have been issued during the last thirty years for the consolidation or codification of the criminal law; but that object has not yet been attained, nor have any really practical measures been adopted for such an annual revision of our statutes as would in a few years naturally produce their consolidation, if not a codification of the law itself. It is thought, however, that the well-grounded impatience of the House of Commons cannot much longer delay the passing of general acts consolidating and so far codifying the criminal law; on this ground it is desirable to abstain from any attempt to enumerate those alterations in details which have been made from time to time. One or two points only need be referred to. The summary jurisdiction recently conferred on magistrates in petty sessions is noticed under LARCENY; the liability of trustees to prosecution for breach of duty, under the head TRUSTEES. Great improvements were effected in the procedure of the courts which take cognisance of crimes by the statute 14 & 15 Vict. c. 100, which abolished all technical objections for misnomers or nondescriptions, and invested the judges with ample powers of amendment. A court of criminal appeal in cases involving questions of law has been established. Finally, transportation as a punishment to be ordered by the court has been abolished by the statute 20 & 21 Vict. c. 3. *Penal Servitude*, as it is termed, created by statute 16 & 17 Vict. c. 99, has been substituted; but criminals sentenced to long terms of penal servitude continue to be transported as before.

Procedure.

Where any indictable crime has been or is suspected to have been committed, the ordinary mode of bringing the accused to justice is as follows:—Unless he surrenders himself, he is, in the first place, to be summoned by some magistrate, having jurisdiction, to appear before him, or, as is more generally the case, a warrant for his apprehension is to be procured from some such magistrate. In order to the issuing of a warrant there must be an information laid on oath. Instead of a warrant the justice may, in his discretion, and on a mere charge or complaint, without a written information or oath, issue a summons in the first instance. After a summons duly issued and served upon the accused, he is to appear according to its directions, or in default the

magistrate may issue his warrant to apprehend him (11 and 12 Vict., c. 42). After a warrant duly granted, whether a summons have been previously issued or not, the person to whom it is directed is to proceed to arrest the accused (and if for treason, felony, or breach of the peace, may do so on any day, and at any time of the day or night), and to take him to jail or before some magistrate having jurisdiction, according to the import of the warrant, and that without any unnecessary delay. It is also lawful for a constable or private person who sees a felony committed, or attempted to be committed, or a dangerous wound given, to arrest the offender, without warrant; also any person whom he reasonably suspects of having committed a felony which has actually been committed, and persons found committing thefts or malicious injuries to property and some other offences, and by the statute, 14 & 15 Vict., c. 18, any one may apprehend a person found committing any indictable offence in the night. A constable may also, without warrant, arrest on a reasonable charge made of a felony committed or dangerous wound given, although it afterwards appear that none such had been actually committed or given; also for a breach of the peace committed in his view; but (except in the case of one of the metropolitan police, who may under certain circumstances do so upon a charge made of an aggravated assault [see 2 & 3 Vict., c. 47]), not for one committed out of his view. Justices of the peace, sheriffs, coroners, and all other peace officers, have, it would appear, the like power to arrest as constables.

On surrendering himself or appearing in obedience to a summons, or being brought before a justice of the peace under a warrant, the justice is to proceed to take the statement on oath of those who know the facts and circumstances of the case, and to reduce those statements into writing, which are then signed by the witnesses and are termed their 'depositions.' These are read to the accused and after being cautioned according to a form provided, he is at liberty to make a statement, which is taken down and transmitted with the depositions to the court, before which the accused is sent for trial. If, however, the justice or justices, are of opinion that the evidence is not sufficient to put the accused party upon his trial for any indictable offence, he is discharged, otherwise, or if the evidence given raise a strong or probable presumption of his guilt, he must either be committed to prison for trial or give bail (see BAIL).

Where a party is committed or bailed for any offence, the justice may bind by recognisance all persons who know or declare anything material touching it, to appear and prosecute, or give evidence against him. When held to bail or committed to prison, the accused is entitled to have delivered to him, on demand, copies of the examinations of the witnesses upon whose depositions he is so bailed or committed, on payment of a reasonable sum not exceeding 1½d. for each folio of 90 words. (11 & 12 Vict., c. 42)

To the above mode of proceeding there are some exceptions.

Under the Juvenile Offenders Acts (10 & 11 Vict. c. 82, and 13 & 14, c. 37), any two justices of the peace in petty sessions, or any magistrate of the metropolitan police-courts, or any stipendiary magistrate, before whom any person is charged with having committed, or having attempted to commit (or with having been an aider, abettor, counsellor, or procurer in the commission of) any offence by law deemed or declared to be simple larceny, or punishable as simple larceny, may, if the age of such person shall not exceed sixteen years, convict him in open court of such offence, and pass a sentence of imprisonment for any term not exceeding three months, with or without hard labour, or impose a fine not exceeding three pounds. If a male not more than fourteen years of age, he may be once privately whipped, either instead of or in addition to such imprisonment. On the other hand, if the justices consider the charge not to be proved, or if proved, that it is not expedient to inflict any punishment, they may dismiss the accused with or without requiring him to find sureties for his future good behaviour.

The accused person may object to the case being summarily disposed of. In order to ascertain his wish on this point, one of the justices, before asking him whether he has any cause to show why he should not be convicted, must inquire, in words prescribed by the statutes, whether he wishes to be tried by a jury; and if the accused or his parent then objects to a summary trial by the justices, they must proceed with the charge against him as if their summary jurisdiction did not exist. If the charge be dismissed, the dismissal is, equally with a conviction, a bar to any further or other proceedings. By the statute 18 & 19 Vict. c. 126, more extensive powers of summarily convicting offenders were conferred on justices. Where any person is charged before justices of the peace at petty sessions (or any magistrate of the metropolitan police district, or any stipendiary magistrate generally) with having committed simple larceny, and the value of the property does not exceed five shillings, or with having attempted to commit larceny from the person, or simple larceny, the justices may, with the assent of the accused, hear and determine the charge in a summary way. In order to do so, the justices, at the close of the examinations of all the witnesses for the prosecution, must state to the person accused the substance of the charge against him, and then inquire of him, in the language prescribed by the statute, whether he consents that the charge shall be so tried, or sent for trial by a jury. In case of dissent, there is an end of all summary proceedings; but if the accused assents to the charge being disposed of summarily, the

justices reduce it into writing; and having read it to the accused, require him to plead thereto. If he says he is guilty, he may be sentenced to three calendar months' imprisonment, with hard labour. If he says he is not guilty, the justices are to hear his defence, and then dispose of the case summarily. On the other hand, if the justices think the charge not proved, they may dismiss it, which has the effect of an acquittal; and even if the justices think the case is legally made out, but that there are circumstances rendering it inexpedient to inflict any punishment, they may dismiss the person charged without proceeding to a conviction.

The summary powers conferred by this statute are not, however, limited to trying offenders in the cases above mentioned; the justices have powers to *punish* in some other cases where the accused admits his guilt. In cases of simple larceny, of stealing from the person, or of larceny as a clerk or servant, irrespective altogether of the value of the stolen property, where the evidence for the prosecution is, in the opinion of the justices, sufficient to put the person charged on his trial, but the case nevertheless appears to them to be one which may properly be disposed of in a summary way, they are to reduce the charge into writing, and having read it to the accused person, to ask him whether he is guilty or not guilty. If he says he is guilty, that plea is entered, and the justices may commit him to jail and hard labour, for any term not exceeding six months; but before the question is put, the justices must explain to the accused that he is not obliged to plead or answer before them at all, and that if he do not so plead or answer he will be committed for trial in the usual course. It must be added, that if it is made to appear that the accused has been previously convicted of felony, the justices have no jurisdiction to dispose of the case summarily.

Before a prisoner can be put upon his trial for any treason or felony, it is necessary that a bill of indictment should be found against him by a grand jury duly returned before some court which has jurisdiction to try parties for crimes by means of a petty jury; or in the case of murder or manslaughter, he may be tried upon the coroner's inquisition. Where the offence with which he is charged is a misdemeanor, he may be tried either upon bill of indictment found, as in the case of treason or felony, or upon a criminal information filed against him in the name of the queen. For a *præmunire*, he is to be first indicted as in other cases, or may be proceeded against in the peculiar manner pointed out by 16 Rich. II., c. 5, commonly called the Statute of *Præmunire*. This latter mode may, however, be regarded as obsolete.

A bill of indictment is an accusation at the suit of the Crown, and being for the public benefit and security, may generally be preferred by any person; but it is not usual for parties to interfere unless they are individually aggrieved by the offence, or fill some office which renders it peculiarly incumbent on them to bring the offender to justice; and a recent statute (22 & 23 Vict. c. 17) has taken away the power to prefer indictments for perjury, conspiracy, false pretences, and some other misdemeanors, without the previous committal of the parties by a justice, or the leave of the court. [INDICTMENT] So soon as the grand jury have presented the bill of indictment in court, indorsed "a true bill," the indictment is complete. If the grand jury find no true bill, the accused, where in custody, is to be at once set at large, without the payment of any fees on account of such discharge (14 Geo. III. c. 20; 55 Geo. III. c. 50; 8 & 9 Vict. c. 114). An indictment may also be framed upon the presentment by a grand jury, of their own knowledge that an offence has been committed; but this mode of prosecution is seldom adopted. For further particulars relating to Grand Juries, see JURY.

A criminal information in the name of the Queen is a suggestion filed on record by the attorney-general or by the queen's coroner or master of the Crown Office, in the court of Queen's Bench, that a misdemeanor has been committed by an alleged offender. The attorney-general, or, during vacancy in that office, the solicitor-general, may at his discretion file a criminal information. In all other cases it is in the discretion of the Court of Queen's Bench to grant or refuse leave to file such informations, and such leave will only be granted on motion made, grounded on proper affidavits, and in respect of misdemeanors of such magnitude or under such circumstances as, in the opinion of the court, call for its interference. After an information is filed, all the subsequent proceedings are, in general, the same as after an indictment found for a misdemeanor.

Persons committed for treason or felony who move in open court the first week of the term, or first day of the sessions of oyer and terminer or jail delivery, to be brought to trial, may, if not indicted some time in the next term or session after their commitment, be bailed by the judges of the Queen's Bench, or justices of oyer and terminer or jail delivery, unless it appear that the witnesses for the crown could not be produced the same term or sessions; and if not indicted and tried the second term or sessions after their commitment, or if acquitted upon their trial, shall be discharged from imprisonment (31 Car. II. c. 2, s. 7). [HABEAS CORPUS ACT.]

When the indictment is found, in cases of felony, the accused is bound to plead and try *instantly*, and if in custody, is to be brought to the bar and arraigned (which is the legal term for calling on a prisoner to answer to a charge of an indictable offence) as soon as convenient after such indictment is found; but in all cases of treason, except where the overt act is the assassination of the queen, the endangering of her

life or person, or any attempt to injure her person (39 & 40 Geo. III. c. 93; 5 & 6 Vict. c. 51), and except the forgery of the great and other royal seals (7 & 8 Wm. III. c. 3, s. 13), the accused is to have a true copy of the indictment delivered to him ten days at the least before he is arraigned, and, at the same time, a list of the witnesses to be produced against him, and if indicted in any other court than the Queen's Bench, a list of the petit jury; but if indicted in the Queen's Bench, the list of the petit jury may be delivered to him at any time after his arraignment, so as it be delivered ten days before the day of trial (7 & 8 Wm. III. c. 3, s. 1; 7 Anne, c. 21, s. 11; 6 Geo. IV. c. 50, s. 21). If the accused plead, however, without claiming or having had delivered to him such copy or lists, he will be considered to have waived any objection on account of such non-delivery. If the accused, whether in case of felony or misdemeanor, be not in custody nor on bail when the indictment is found, or, being on bail, make default, his appearance may be compelled by process or by a bench warrant; and he may be prosecuted to outlawry. [OUTLAWRY.] No fee is to be demanded or taken from persons charged with or indicted for felony or misdemeanor, or as an accessory to felony, for their appearance to the indictment or information, or for allowing them to plead, or for recording their appearance or plea, or for discharging any recognisance taken from such persons, or any sureties for them (8 & 9 Vict. c. 114, s. 1).

In cases of treason, the accused is entitled, on application to the court, to have two counsel assigned him, who may have free access to him at all reasonable hours (7 & 8 Wm. III. c. 3, s. 1). The court may also, if it think fit, upon the accused's making affidavit that he is not worth 5*l.* beyond his wearing apparel, allow him to defend *in forma pauperis*; in which case neither the officers of the court, nor those who are assigned to conduct his cause, may take any fees.

The prisoner, upon being arraigned or charged with the indictment, in cases of felony or misdemeanor, may either confess the charge to be true, in which event such confession is to be recorded and judgment awarded according to law, or may plead to the indictment or demur. By pleading, he puts in issue the facts of the charge; by demurring, he admits the facts, but contends that they amount to no offence indictable by law; as, if a man were indicted for feloniously stealing game, without alleging that it was tame or confined; in which case, upon demurrer, he must be discharged. After demurrer, in cases of felony or misdemeanor, decided against the prisoner, he is not at liberty as a matter of right to plead over "Not Guilty" (Reg. v. Faderman, 1 Den. c. c. 569), but the court may permit him to do so. In either case, if the demurrer be decided for the prisoner, the judgment is that he be dismissed and discharged.

The pleas which may be pleaded by a prisoner are either to the jurisdiction of the court, and these must be pleaded before any other plea, or in abatement (now almost unknown), or in bar; and pleas in bar are either special pleas or the general issue. Special pleas may allege a previous acquittal, conviction, or attainder of the same offence, or a pardon [PARDON]; and, in the case of prosecutions for the non-repair of highways or bridges, the liability, if denied by the defendant, of the party who is liable for the repair of the same.

The general issue, or "Not Guilty," which is the plea employed in the infinitely greatest number of cases, puts in issue the whole question of the accused's guilt or innocence of the charge in all its bearings; and not only casts on the prosecutor the burden of making out every part of his charge, but entitles the accused to give in evidence every possible ground of justification or excuse which can form an answer to the indictment.

No advantage can now be obtained by a plea in abatement, as by the 7 Geo. IV. c. 64, s. 19, the court may, upon such plea, immediately cause the indictment to be amended, and call upon the party to plead to it so amended, as if no such plea had been pleaded. In cases of felony, if a special plea be found for the crown, the prisoner may plead over "Not Guilty;" but in cases of misdemeanor, the judgment for the crown is final. In either case, if it be found for the prisoner, he is to be dismissed.

If, instead of pleading, the prisoner stand mute of malice, or will not answer directly to the indictment, the court may order a plea of "Not Guilty" to be entered on his behalf, and such plea will have the same effect as if it had been actually pleaded by him (7 & 8 Geo. IV. c. 28, s. 2). But if a doubt arise whether he be mute of malice or dumb, a jury is to be impaneled to try the fact, and, if the latter be found, the court will use means to make the prisoner understand what is required of him; but if this be impossible, will direct a plea of "Not Guilty" to be entered, and the trial to proceed. Should he upon arraignment be found to be insane by a jury impaneled for the purpose under the provisions of the 39 & 40 Geo. III. c. 94, so that he cannot be tried, the court may order such finding to be recorded and the prisoner to be kept in strict custody until her Majesty's pleasure be known.

When, however, the plea of "Not Guilty" has been pleaded, the trial is to be had before some court having jurisdiction, by twelve jurors, generally of the county where the fact is alleged in the indictment to have been committed, called a petit jury, by way of distinction from the grand jury. The ordinary courts having jurisdiction to try indictable offences are the Queen's Bench, the Central Criminal Court, Courts of Oyer and Terminer, Gaol Delivery, and Quarter-Sessions

Borough Courts and the Superior Criminal Courts of the Counties Palatine; but Courts of Quarter-Sessions and Borough Courts have no jurisdiction with respect to treason or any felony punishable with death or transportation for life, or several other offences (5 & 6 Vict. c. 38, s. 1). The trial is generally to be had in the county or district in which the offence was committed.

Upon the trial being called on, the jurors are to be sworn as they appear, to the number of twelve, unless they be challenged. As to challenges, whether on the part of the crown or the prisoner, and as to petit juries generally, see JURY. It may here be observed, however, that the right of peremptory challenge, that is, of challenging at mere pleasure, without showing any cause, which exists in cases of treason and felony, is one of the peculiarities before alluded to, which distinguish those classes of crime from misdemeanors; and that the power to challenge peremptorily to the number of thirty-five jurors in cases of treason, and to the number of twenty only in cases of felony, is a distinguishing feature between treasons and felonies. When twelve jurors are procured free from exception, and have been sworn, or, if Quakers, Moravians, or Separatists, or persons who have been Quakers or Moravians, have made their solemn affirmation, in case of treason or felony, well and truly to try and true deliverance make between the queen and the prisoner whom they have in charge, and, in cases of misdemeanor, well and truly to try the issues joined between the queen and the defendant, the case, where counsel is retained for the prosecution, is to be opened by him, or, if two or more counsel are retained, by the leading one, according to his instructions, unless the case is so plain as not to require any statement. The counsel for the prosecution ought, however, to confine himself, so far as possible, to a simple statement of the facts which he expects to prove, and to abstain from any appeal to the passions of the jury, more particularly in cases where the prisoner has no counsel. After the opening, or, where no counsel is engaged for the prosecution, immediately after the swearing of the jury, the examination of the witnesses on behalf of the Crown commences. Before being examined an oath or affirmation is administered to each witness "that he will true answer make to such questions as the court shall demand of him, and will tell the truth, the whole truth, and nothing but the truth." Where there is counsel, he examines the witnesses; where there is none, that duty devolves on the court. In criminal cases a single witness, swearing to the actual offence, or to such facts as necessarily lead to the inference that it has been committed, if believed by the jury, is generally sufficient to substantiate the charge. In treason, perjury, and the offences of tumultuously petitioning, affirming that parliament has a legislative authority without the crown, or that any person is entitled to the crown contrary to the Act of Settlement, and blasphemy under the provisions of 9 & 10 Wm. III. c. 32, however, there must be two witnesses. In all cases, also, the prisoner's confession, if made in consequence of a charge against him, and in a direct and positive manner, voluntarily and without promise or threat operating on his mind at the time of making it, is sufficient, even if there be no other proof that the crime with which he is charged has been committed, for the jury to convict upon, if they believe it to be true. And the single unsupported testimony of an accomplice is sufficient (except where two witnesses are required), if the jury believe his story; but it is usual in such cases for the court to direct the acquittal of the prisoner. If, however, the accomplice be corroborated by unsuspicious evidence as to such parts of his testimony as show that his story has not been fabricated, the court will not interfere.

There are four kinds of proof by which criminal charges may be sustained: 1, *positive*, as by the direct testimony of a witness who saw the fact; 2, *circumstantial*, when a number of facts are presented which are inconsistent with any other hypothesis than that of the prisoner's guilt; 3, *presumptive*, as when the possession of a stolen article casts on the prisoner the burden of showing how he obtained it; 4, *confessional*, where the prisoner makes a voluntary admission of his guilt, as already mentioned. The general rules of evidence in criminal proceedings are the same as those which are applicable in civil cases. [EVIDENCE.] A husband or wife of an accused person, however, cannot be a witness for or against each other (unless upon a charge of criminal violence done by either to the person of the other) contrary to the rule in civil cases, which now admits the testimony of husband and wife for or against each other. The prosecutor, also, notwithstanding his connection with the proceedings against the prisoner, is a competent witness in support of the charge; for such proceedings are carried on in the name of the crown, and the prosecutor has, according to legal construction, no direct interest in the result. His wife, therefore, may be a witness either for the prosecution or for the prisoner.

In the event of the death or illness of a witness, his deposition may be read. In criminal cases, too, instruments are admitted in evidence, although not duly stamped. (17 & 18 Vict. c. 83, s. 27.)

After the examination of each witness, he may be cross-examined on behalf of the prisoner. When the cross-examination is finished, the counsel by whom the witness was called is entitled to re-examine him for the purpose of explaining any matters touched upon or referred to in the cross-examination, into which confusion may have been introduced by the questions on the prisoner's behalf. The court may also put any question it thinks proper to the witnesses, and for this purpose may recall a witness at any stage of the inquiry.

When the case for the prosecution is closed, the prisoner or his counsel (who has, since the passing of the 6 and 7 Wm. IV. c. 114, the same right to address the jury on the merits of the case in felony as he previously had in treason and misdemeanor) is entitled to address the jury, and in so doing to comment on the entire case for the prosecution; and if he intends to adduce evidence, may open that evidence with any particulars he may think proper. After the prisoner or his counsel has finished his address, the witnesses for the defence are to be sworn, and their evidence gone into. The accused is always allowed to call witnesses to speak to his *general* character, as being inconsistent with the imputed offence, and it is for the jury to estimate the value of such evidence.

When the prisoner's evidence is closed, witnesses may be called on behalf of the prosecution to give specific contradictions to the denials by the prisoner's witnesses on cross-examination, and generally to give any evidence in reply which is strictly applicable to the defence and which could form no part of the original case. Where such evidence is given, the prisoner or his counsel has a right to address the jury on it before the general reply for the prosecution.

When the defence is ended, the counsel for the prosecution, in all cases where witnesses have been called on behalf of the accused, is entitled to reply on the entire case and on all the observations made by the other side during its progress; but in practice, where the evidence given on behalf of the accused is confined to character, it is not usual to reply. After the case on both sides is closed, the court sums up the evidence, and in so doing directs the attention of the jury to the precise issue they have to try, and applies the evidence to that issue. Upon the trial of a person for a non-capital felony committed after a previous conviction for felony, the jury is not to be charged to inquire concerning such previous conviction, until they have inquired concerning such subsequent felony and have found such person guilty of the same; and where such previous conviction is stated in the indictment, the reading of such conviction to the jury is to be deferred until after such finding. Where, however, such person gives evidence of good character, the prosecutor may in answer thereto give evidence of such previous conviction, before such finding, and the jury may inquire concerning such previous conviction at the same time that they inquire concerning the subsequent felony. (6 & 7 Wm. IV. c. 111; 14 & 15 Vict. c. 19.) The summing up being concluded, the jury proceed to consider their verdict. If, on consultation in the jury-box, they are not able to agree within a convenient time, they retire, and a bailiff is sworn to keep them together without meat, drink, fire, or candle till they are agreed. This rule, however, has been relaxed in modern times. In cases of misdemeanor, where the trial lasts more than one day, the court will generally allow the jurors to return to their homes, the jury engaging to allow no one to speak to them on the subject of the trial. But in cases of treason or felony, the course has been to permit them to retire in a body to some tavern, where accommodation is provided for them by the sheriff and his officers, who are sworn to keep them together, and neither to speak to them themselves nor to suffer any other person to speak to them touching any matter relating to the trial.

When the jury have agreed upon their verdict, they signify that they are ready to deliver it; and on returning into court for that purpose, their names must be called over, and all twelve must be within hearing when it is given. The foreman of the jury is the person who is to deliver the verdict; and in cases of treason or felony, it can only be received in open court and in the presence of the prisoner: in cases of misdemeanor it may be otherwise. The verdict may be either "Guilty" or "Not Guilty," or may be a special one; and may be "Guilty" upon one count of an indictment, and "Not Guilty" upon others; or may be "Guilty" as to part of a count, and "Not Guilty" as to the remainder, where an offence is charged which includes a lesser crime of the same degree, and the latter only is proved; as where murder is charged, and the proof is of manslaughter; and persons indicted for the actual commission of felonies or misdemeanors may be convicted of the attempt (14 & 15 Vict. c. 100, s. 9.) A special verdict is the finding of all the facts specially, where the jury doubt whether they constitute the offence in the indictment, and leaves the court to give judgment according to the legal effect of the facts so found.

Where upon the trial evidence is given of insanity at the time of committing the offence charged, and the jury acquit, they are required to find specially whether the accused was insane at the time of the commission of the offence, and whether he was acquitted on that account; and if they find in the affirmative, the court is to order him to be detained till the queen's pleasure be known; and she may give such order for his safe custody during her pleasure as she may think fit. (39 & 40 Geo. III. c. 94, s. 1; 3 & 4 Vict. 3. 54, s. 3.) On a verdict of acquittal, or where he is discharged by proclamation for want of prosecution, the prisoner is to be immediately set at large in open court, without the payment of any fines in respect of such discharge. (14 Geo. III. c. 20; 55 Geo. III. c. 50; 8 and 9 Vict. c. 114.)

When a verdict of guilty has been returned against a prisoner, the court, except in the case of prosecutions pending in the Queen's Bench, may proceed at once to pass sentence upon him, unless he allege some matter or thing sufficient in law to arrest or bar judgment. In prose-

cutions pending in the Queen's Bench, however, the prisoner is allowed four days for moving in arrest of judgment; or, in cases of misdemeanor, for a new trial or writ of *venire facias de novo*. Also where the trial at any sittings or assizes is upon a record of the Queen's Bench, the judge before whom the verdict is taken may, under 11 Geo. IV. & 1 Wm. IV. c. 70, s. 9 (except where the prosecution is by information filed by leave of the Queen's Bench, or such cases of information filed by the attorney-general wherein he prays that judgment may be postponed), pass sentence at once; but such sentence is not to have the force and effect of a judgment of that court, until after the expiration of six days after the commencement of the ensuing term, during which period the prisoner may move for a new trial, or to have the judgment amended. Except in the last-mentioned case of a trial at the sittings or assizes upon a record of the Queen's Bench, or where the offence of which the prisoner is convicted is a misdemeanor punishable by a simple fine, or where the Queen's Bench, after conviction for misdemeanor, thinks proper to dispense with his attendance, sentence cannot be pronounced against a prisoner unless he be present in court at the time.

Judgment may be arrested where the offender has received a pardon since his arraignment or after conviction becomes insane, or, having been out of custody since his conviction, denies that he is the person convicted (in which last case a jury is to be impaneled to try the fact), or for some defect apparent in any part of the record, as regards either the jurisdiction of the court, the statement of the offence or any of the proceedings thereon, but not for any of the mere technical defects specified in 7 Geo. IV. c. 64, ss. 20 and 21. If the judgment be arrested, all the proceedings against him are to be set aside, and judgment of acquittal is to be pronounced in his favour; but he may be prosecuted again for the offence of which he is so acquitted.

A new trial may be had on the application of the defendant in all cases of misdemeanor pending in the Queen's Bench, where it appears to the court that the awarding one is essential to justice; as, for instance, where the verdict is contrary to evidence or the directions of the judge, or evidence has been improperly received or rejected at the trial. The court of Queen's Bench will also in its discretion, where a party is acquitted of a misdemeanor on a prosecution pending in that court, allow a new trial, on the application of the prosecutor, if such acquittal has been obtained by any fraudulent means or practice, as where the party acquitted has kept back any of the prosecutor's witnesses, or neglected to give due notice of trial.

A writ of *venire facias de novo*, the effect of which is the same as granting a new trial, may be awarded where, by reason of misconduct on the part of the jury, or of some uncertainty or ambiguity or other imperfection in their verdict, or of any other irregularity or defect in the proceedings or trial, appearing on the record, the proper effect of the first *venire* has been frustrated, or the verdict has become void in law.

Neither new trials nor writs of *venire facias de novo* are grantable in cases of treason or felony.

Where a new trial or writ of *venire facias de novo* is awarded, the parties stand in the state in which they were immediately before the first trial: the whole case is to be re-heard, and the first verdict cannot be used upon the new trial, or as evidence of any matter found by such verdict, or in argument.

After sentence pronounced against an offender, the judgment of the court may be falsified or reversed, either by plea without writ of error or by writ of error: by the former, for some matter not apparent upon the face of the record, as want of authority in the court by whom the judgment was pronounced; by the latter, for the same matters as are sufficient to arrest a judgment, and also for any material defect in the judgment itself. Where the judgment has been pronounced by a court of oyer and terminer, jail delivery, or quarter-sessions of the peace or of a county palatine, the writ of error is to be brought in the court of Queen's Bench, and for that purpose the indictment and other proceedings thereon must be removed into that court by writ of *certiorari* [CERTIORARI]: where it has been pronounced in the Queen's Bench, it is to be brought in the Exchequer Chamber, before the justices of the Common Pleas and barons of the Exchequer, from whose judgment a writ of error lies to the House of Lords. In cases of treason and felony it is in the discretion of the crown to grant or refuse a writ of error: in all other cases the fiat of the attorney-general must be first obtained, and this he ought to grant upon probable cause of error shown. When issued, the writ of error stays the execution of the judgment, where it has not been carried into effect during the time that such writ is pending, except that in cases of treason or felony the offender is not entitled to be liberated on bail. In cases of misdemeanor, however, where he is imprisoned under execution, or any fine has been levied, either in whole or in part in pursuance of the judgment, he is entitled to be discharged from imprisonment and to receive back any money levied on account of such fine, until the final determination of the Writ of Error. (8 & 9 Vict., c. 68, s. 1.) If the judgment be falsified or reversed, such judgment and the execution thereupon, and all former proceedings, become thereby absolutely null and void; and the person the judgment against whom is so falsified or reversed, if living, and, if dead, his heir or executor, is restored to all things which such person may have lost by such judgment and other

proceedings, and stands in every respect as if such person had never been charged with the offence in respect of which such judgment was pronounced against him. If, however, the execution only be erroneous, that only will be reversed; and if the judgment be reversed for some technical error merely, in the indictment or subsequent process, the party may be prosecuted again. If the judgment be confirmed, the prisoner is to be remanded to undergo the remainder of his sentence.

Where there is nothing to arrest or bar a judgment, the execution of it may be prevented by a pardon received after sentence pronounced; but, without express words of restitution, no property which the offender forfeited on his conviction or attainder, is thereby re-vested in him; nor, unless where the pardon is by act of parliament, is the corruption of his blood removed, except as regards those of his blood born after the granting of such pardon, nor are any of the consequences of such previous corruption prevented.

In capital cases the execution of a judgment may also be suspended by a reprieve, either at the discretion of the Crown, or, where substantial justice requires it, of the court. There are two instances, however, in which the court is bound to grant a reprieve, viz.: 1, where the offender, if a female, is pregnant; 2, where the offender becomes insane after judgment. If the offender allege that she is pregnant or the court have reason to suppose that she is so, a jury of twelve matrons is to be impaneled with all possible despatch to try whether or not she be quick with child. In case they find in the affirmative, the court respites the offender from time to time until she be delivered of a child or it is no longer possible in the course of nature that she should be so. After her delivery or where such delivery is no longer possible as before mentioned, or if the jury find that she is not quick with child, the court at the expiration of the period for which it has respited her, proceeds to award execution against her.

Where insanity is alleged, the court will reprieve the prisoner, if found to be insane by means of an *ex officio* inquiry, or if his insanity otherwise sufficiently appear.

Although there is no right of appeal in criminal cases, a court has been recently formed for the consideration of crown cases reserved. A practice had long existed for the judges on circuit to receive any objections taken on behalf of the accused, which appeared to them worthy of mature consideration, for the opinion of all the judges; and if they, or a majority of them, came to the conclusion that the objection was well founded, the defendant was recommended to the crown for a pardon. Although the decision of the judges in such cases was known, the reasoning by which they arrived at the conclusion did not transpire: while the power of reserving questions of law was not possessed by the courts often most in need of the assistance of the judges on such points, namely, the courts of quarter sessions. Now, however, by the statute 11 & 12 Vict. c. 78, reciting that "it is expedient to provide a better mode of deciding any difficult question of law arising in criminal trials," it is enacted that when any person has been convicted of any treason, felony, or misdemeanor before any court of oyer and terminer, or gaol delivery, or court of quarter sessions, the judge, or commissioners, or justices of the peace before whom the case has been tried, may in his or their discretion, reserve any question of law which has arisen on the trial for the consideration of the justices of either bench and barons of the exchequer; and may respite execution, or postpone the giving of judgment until such question has been decided, and in the meantime either commit the person convicted to prison or admit him to bail.

For the purpose of considering such questions (which are transmitted to them in the form of a special case) the judges meet, five at the least being required, including one chief justice or the chief baron, to constitute a court for the consideration of crown cases reserved, as it is termed, on one or more days in each term; and then in open court deliver their judgment either upon or without argument, reversing, affirming, or amending the judgment already given, or where the conviction is affirmed and no judgment has been already given, ordering when and where it shall be given.

The court which determines these reserved questions of criminal law, is not a court of criminal jurisdiction or appeal in the legal or ordinary sense of the term. It merely assists and guides with its opinion the determination of the court or judge below, in whose discretion is exclusively vested the reservation of the case, and to whom, or to his successor, the judgment (if the conviction be affirmed) is wholly left.

Should the execution of a judgment be neither prevented nor suspended, or, having been suspended, should have ceased to be so, such judgment is to be executed according to law by the sheriff or other authorised person or his deputy. In capital cases, if the offender, after hanging, be taken down before he be dead, he is to be hanged again until he be dead.

As regards the manner in which the various judgments which may be pronounced against offenders are to be executed, the subject is too extensive to be further treated of in an article like the present.

As to the restitution of stolen property, see RESTITUTION. With respect to the expenses of prosecutions for indictable offences, the general provisions on the subject are contained in 7 Geo. IV. c. 64. According to these the court before which any person is prosecuted for felony or the following misdemeanors, namely, assaults with intent to

commit felony; attempts to commit felony; riots; receiving stolen property; assaults upon peace-officers in the execution of their duty, or upon persons acting in their aid; neglect or breach of duty by peace-officers; assaults in pursuance of conspiracies to raise the rate of wages; obtaining property by false pretences; indecent exposure of the person; perjury and subornation of perjury, may, at the request of the prosecutor or any other person appearing on recognisance or subpoena to prosecute or give evidence, order payment of the costs and expenses incurred by the prosecutor in preferring the indictment, and also the reasonable expenses of the prosecutor and witnesses for the prosecution in attending before the grand jury and otherwise carrying on the prosecution; and also, whether a bill of indictment be preferred or not, may order the reasonable expenses incurred by any person by reason of attending on any such recognisance or subpoena (such attendance, where no indictment is preferred, appearing to be in *bonâ fide* obedience to the recognisance or subpoena), and, except in cases of misdemeanor, by reason of attending before the examining magistrate, and also, except in respect of attendance before such magistrate in cases of misdemeanor, compensation for trouble and loss of time.

It is difficult to discover upon what principle the selection of the cases of misdemeanor in respect of which the court is empowered to award costs under the above statute was made. Subsequent statutes have however extended the power to indictments for concealment of birth, fraudulently procuring the defilement of women or girls under twenty-one, assaults upon workhouse officers, or relieving officers, neglecting to provide for, or assaulting apprentices or servants; offences under the statute 14 & 15 Vict. c. 19, comprising serious assaults on the person, being found by night armed with intent to commit burglary, &c.; carnally knowing and abusing girls; abduction of unmarried girls under sixteen; conspiring to charge any person with felony, and conspiracy to commit felony; and assaults prosecuted by direction of justices. Other cases might with justice be included; and it may be a question whether, under certain limitations, the power ought not even to be extended to the expenses of the prisoner's witnesses. The costs are taxed by the officer of the court, and paid by the treasurer of the county, who is repaid by the Treasury out of the consolidated fund. (15 & 16 Vict. c. 82.)

Offences punishable on Summary Conviction.

It would be inconsistent with the limits of the present article to give a detailed account of the various offences punishable on summary conviction, in number far exceeding those which are indictable. They relate, however, principally to ale and beer houses, apprentices, petty assaults, the Customs and Excise, distresses, drunkenness, friendly societies, game, hawkers and pedlars, highways, turnpike roads, petty thefts not amounting to larceny, malicious injuries to property, pawn-brokers, railways, stage and hackney carriages, servants, vagrants, weights and measures, and the numerous offences punishable under the Metropolitan Police Acts.

Summary proceedings, except in the case of contempts of the superior courts of justice (which those Courts have been immemorially used to punish by attachment), were wholly unknown to the common law. Their institution appears to have originated partly in the necessity for relieving the ordinary tribunals from the immense increase of labour which would otherwise have been cast upon them, owing to the multiplicity of new offences of a trivial kind which were yearly created for the protection of society as it advanced in population and civilisation, and partly in the desire to do more speedy justice in the case of such trifling offences than would have been possible had they been made indictable. In the case of indictable offences a party cannot in general, as before observed, be put upon his trial until a true bill has been found against him by a grand jury, and cannot be convicted except by the verdict of a petit jury: to have made all these minute offences indictable would therefore have entailed upon the class of persons qualified to serve as jurors a frequency of attendance which would have been found to be most troublesome and harassing. Accordingly numerous acts of parliament have from time to time vested in one or more justices of the peace or other persons the power to try parties accused of trifling offences without the intervention of a jury. The extension, however, of this mode of proceeding has been always regarded with extreme jealousy.

The course of proceeding before justices, as far as regards summary convictions, was until recently regulated by a great variety of statutes, extending from the 18 Eliz. c. 5, to the 6 & 7 Wm. IV. c. 14. These acts have been consolidated, and the duties of the justices clearly defined by the statute 11 & 12 Vict. c. 43, which provides a procedure applicable to the great majority of cases in which a summary conviction or order may be made by justices of the peace out of sessions.

Where an information is laid before a justice or justices of the peace, that any person has committed, or is suspected to have committed any offence or act for which he is liable by law, upon a summary conviction for the same, to be imprisoned or fined, or otherwise punished, and who, when a complaint is made to any justice or justices, upon which he or they have authority by law to make any order for the payment of money or otherwise, such justice or justices are to issue a summons in a prescribed form directed to the party charged, stating shortly the matter of such information or complaint, and requiring him to appear and answer the same, and be further dealt with according to law.

This summons must be served by a constable, peace officer, or other person to whom it is delivered, on the person to whom it is directed, either personally, or by leaving the same at his last or usual place of abode.

If the person so summoned does not appear after having been served a reasonable time, the justices, upon proof to their satisfaction, substantiating the matter of the information or complaint, may issue a warrant to apprehend the accused, or may proceed *ex-parte*.

In the case of an information being laid, and satisfactorily substantiated by oath or affirmation, a warrant may be issued in the first instance; but the usual course is, in the first instance, to proceed by summons. The warrant in either case must be under the hand and seal of the justice or justices, and be directed to the constable. It must state shortly the matter of the information or complaint on which it is founded, and it remains in force until executed.

Summonses (followed by warrants if necessary), may be issued to compel the attendance of witnesses for either party.

The information or complaint is to be heard and determined by such number of justices as the particular act of parliament on which it is founded may provide, or when there is no such direction, before any one justice.

The room or place in which the proceeding takes place is to be deemed an open court, to which the public are to have free access; and the defendant may make his full answer and defence, and have the witnesses examined and cross-examined by his counsel or attorney.

When the justices have heard what each party has to say, and the witnesses, they consider the whole matter and proceed to convict, or make an order on the defendant, or to dismiss the information or complaint; every conviction or order being drawn up in a prescribed form, and lodged with the clerk of the peace, and a certificate of every order of dismissal being also given to the defendant.

It is competent to the court to award costs, either against the defendant or against the complainant, as the case may be; and for the amount of such costs, or of any pecuniary penalty, to issue a distress warrant. When there is no distress to be found, or when the statute simply directs imprisonment, a warrant of commitment issues. If the parties are satisfied that a warrant of distress would be ruinous to the defendant, or that he has no goods, the court is authorised to issue a warrant of commitment in the first instance.

It must be observed that the statute 11 & 12 Vict. c. 43, does not extend to informations, complaints, or proceedings relating to the excise or customs, stamps, taxes, or post-office, nor to the removal of paupers, nor to complaints or orders with respect to lunatics or bastards, nor to proceedings relating to the labour of children in mills or factories.

For the method of proceeding with respect to such offences, reference must be made to the statutes on the subject.

The principal authorities besides the statutes of the realm which have been consulted in the preparation of this article, are Hawkins's 'Pleas of the Crown'; Blackstone's 'Commentaries,' by Kerr; Russell, 'On Crimes and Misdemeanors'; Chitty's 'Criminal Law'; Starkie's Treatises 'On the Law of Evidence and On Criminal Pleading'; Dickenson's 'Guide to the Quarter-Sessions,' by Talfourd; the various Reports of the Criminal Law Commissioners; and Paley 'On Convictions,' by Macnamara.

LAW MERCHANT. [LEX MERCATORIIUS.]

LAWN, a space of ground covered with grass, kept short by mowing and generally situated in front of a house or mansion, or within the view from such. The number of evergreen exotics which survive our winters, and the verdure of the grass in summer, are peculiar features of England in comparison with continental Europe, where in general the grass is either burned up in summer, or the exotics are destroyed by the severity of winter. The management of a lawn is with us therefore a subject of interest to every possessor of a garden.

Previous to laying down, the ground intended for a lawn should be properly trenched and drained, in order that such trees and shrubs as may afterwards be planted upon it should succeed well. The direction of the trenches should be towards a drain, to which, if possible, their bottoms should form a regularly inclined plane, for the purpose of affording the means of escape for the water, which, in retentive soils more especially, would otherwise stagnate. Although trees and shrubs are absolutely necessary for giving due effect to the scenery of a lawn, yet in the latter, one open extensive space, lying in the full view from the windows of the house, must be preserved. For this portion, digging instead of trenching may be found sufficient; but the openings, which ought to command views from this principal area, should be trenched, as well as for the shrubs and trees; for if the operation were only performed with regard to the latter, the water would not find such free egress from the bottom as would be the case if the mode of trenching were adopted as is above recommended.

After trenching, the soil should be allowed to subside, and the greatest care should be taken to make the surface perfectly even, otherwise a great expense will be afterwards incurred by the loss of time in mowing, which can neither be so quickly nor so well performed where the surface is uneven.

If turf can be readily procured, a lawn is at once produced; and by such means a more uniform distribution of grass may be obtained than by any other means. The surface of a well-fed meadow, or of an

old common, closely cropped by sheep and geese, affords the best kind of turf; and if any tall or coarse grasses should be mixed with it, no inconvenience will arise, for everything of this sort will eventually disappear under close mowing; and such only as are dwarf and suited to the soil will ultimately remain. Where a turf is to be produced by sowing, the seeds of such species as are indigenous to the locality, and possess at the same time the property of being dwarf and fine, are to be preferred; but in the event of this method of forming a lawn being adopted, it is always desirable that a narrow slip of good turf should be carried all round the circumference. The following species may be mentioned as proper for a lawn in average situations:—*Lolium perenne*, or rye-grass; *Poa trivialis*, or *pratensis*; *Anthoxanthum odoratum*, or sweet vernal; *Cynosurus cristatus*, or crested dogtail, with a considerable quantity of *Medicago lupulina*, or black nonsuch, and *Trifolium repens*, or Dutch white clover. If the situation is particularly dry, *Festuca ovina*, or sheep's fescue, should be substituted for *Lolium perenne*; if very low and wet, then the place of the latter may be filled with *Alopecurus pratensis*, or meadow foxtail. All these grasses may be procured of dealers in agricultural seeds; it is however better for persons in the country to collect for themselves such as can be found in their neighbourhood, for then they can depend upon their being genuine. The utmost care should be taken to avoid the introduction of *Dactylis glomerata*, or cocksfoot grass, and *Holcus lanatus*, or *mollis*, for these hard, harsh, stubborn grasses resist the effects of mowing for a long time. The great plague of lawns is the dandelion (*Leontodon taraxacum*), which should be carefully rooted out as soon as seen, though there is no guarding against seeds.

The process called inoculating, or of making lawn by sowing the ground with fragments of turf, and rolling them in, cannot be recommended when a lawn is required to look particularly well, for it is a long while before the surface of the ground becomes uniform under such circumstances.

Lawns, when once established, require only to be kept neat by the ordinary routine of rolling, mowing, and sweeping, except keeping the surface perfectly even, by making up small hollows, with screened mould, early in spring. When lawns become worn out, a top-dressing of any finely-divided manure will refresh them: malt-dust applied in October is excellent for this purpose; and at the same time an additional quantity of grass-seed may be sown. Where the walks are straight, the edges of the lawn adjoining them should be perfectly straight also, and care should be taken that the grass-edging is kept rolled down and pared, so as never to exceed an inch and a half above the level of the walk.

The lawn, however, in the case of mansions of any architectural pretensions, should not be brought up close to the building; but there should be intervening terraces with flower beds. Where the mansion is dropped, as it were, upon the lawn, it takes an air of incompleteness as well as coldness. The domains of art and nature should be harmoniously united, and not brought into abrupt contrast. This plan is now almost uniformly adopted alike by eminent architects and decorative gardeners.

(Lindley, *Theory and Practice of Horticulture*; McIntosh, *The Book of the Garden*.)

LAY-BROTHERS, pious but usually illiterate persons, who devoted themselves in some convent to the service of the religious. They were usually employed as agriculturists at the grange or farm, or as artisans in the house; and were not admitted under 24 years of age, or above 43. A lower class of these were *Oblati*, who devoted themselves to more menial servitude. There were also *Fratres ad succurrendum*, assistant brothers, who wore only a short scapulary, while the professed lay-brother had the habit of the order, but wore their beards while the monks shaved. The institution of lay-brothers of the professed kind began in the 11th century. The Jesuits termed their lay-brethren *coadjutores*. There were *lay-sisters* also in the nunneries, whose duties consisted in washing, cooking, weaving, attending on the professed nuns, and other menial offices. They were not admitted under 20 years of age. (Fosbrooke's *British Monachism*.)

LAYERING is an operation by which the propagation of plants is effected by laying down or bending the shoots, so that a portion of them can be covered with earth. A shoot so operated on is called a *layer*, and the point which furnishes the layers bears the name of *stool*. Some plants are so much disposed to emit roots that if their branches happen to come in contact with the earth they immediately begin to strike. But although it may be easily imagined that the observation of this common circumstance has led to the artificial practice, yet some additional operations besides that of merely bringing a shoot in contact with the earth are found necessary for many plants on which this mode of propagation is practised. The principle by which the operation is rendered effectual for the object in view is the following:—When the shoot of a species not freely disposed to send forth roots has merely its bent part inserted in the earth, the woody matter organised by the leaves passes down to the roots nearly as usual; but if the communication along the alburnum is interrupted by an acute bend, twist, or incision, a *callus* will be formed, from which by degrees spongioles are emitted, and thus roots ultimately produced. A common error is to bury the layer too deep in the earth; for trees and shrubs, the depth should be from three to six inches, and the shoots of the previous season are the best fitted for the

operation, the incision being made immediately under a bud or joint.

The part of the shoot intended to form a layer should be divested of leaves where it is to be covered with the mould, and a slit should be made on the bent part, or the branch should be twisted half round at the bend so as to disarrange the woody tissue, or the bark should be half or three-quarters *ringed*: the top of the shoot being bent gently upwards in order to give the plant an upright tendency in its after growth, while at the same time that position keeps the incision from closing; the branch is then fixed down by pegs or hooked sticks, cut down to within an inch or so of the ground, and covered with good mould, which should have been previously well stirred, and afterwards be kept tolerably moist. In general roots are emitted in a few weeks, and by the end of a season young plants are obtained quite fit for transplantation. Some plants however require to be left for two years on the stools before they are removed, and there are some which can hardly be made to root at all in this manner.

Plants so situated as to render it impossible to bend their branches to the ground may nevertheless be layered by having their shoots introduced into a pot or box of soil elevated to them, and supported in a convenient position. This is a common practice among the Chinese, who cause branches of trees to root in this manner by partially ringing them, and covering the parts so ringed with a ball of clay, which is kept moist.

LAZARETTO is the name given to certain buildings and enclosures which are annexed to seaport towns, chiefly in the Mediterranean, for the sake of keeping therein confined the crews of ships and passengers arriving from Turkey, or other places where the plague, or other disease deemed contagious, is known to prevail. The persons thus confined are said to be in quarantine, from the Italian word *quaranta*, "forty," because the period of confinement for those arriving from actually infected places is forty days, after which, if no one has fallen ill, they are set at liberty. A lazaretto generally consists of various detached buildings with courts between, the whole surrounded by a wall, and placed in airy situations outside of the town, and on the sea-shore, and in some instances on a small island or rock near the coast. Besides the lodging-houses for persons in quarantine, there are large warehouses in which goods capable, or supposed to be capable, of communicating the disease, such as wool, cotton, leather, &c. are purified. This purification is effected by spreading them out in the air for a length of time, and stirring and turning them about, which is done by the "guardiani," or keepers of the establishment, who, it is supposed, if there were any infection, would speedily take it. These "guardiani" are kept in strict quarantine, but are well paid for the confinement and risk. These establishments are kept under very strict regulations, any infringement of which is visited by severe penalties, amounting in some cases to death. The principal lazarettos were those of Venice, Leghorn, Marseille, Trieste, Genoa, Messina, and Malta. That at Marseille occupied fifty acres, but has been lately taken in to enlarge the town. The name "lazaretto" is derived from St. Lazarus, who, in the Roman calendar, is the patron of lepers, and as leprosy was a very common disease in Italy and other parts of Europe during the middle ages, the hospitals in which lepers were confined obtained the name of lazaretto, and the lepers themselves were called *lazzari*, a word which has perpetuated itself in the *lazzaroni*, or lowest class of the inhabitants of Naples, because, as some believe, of their dress, which resembles that which was worn at one time by the lepers. Houses for lepers in England were often called *lazar-houses*. John Howard wrote 'An Account of the principal Lazarettos in Europe,' 4to., 1789, republished in London, 4to., 1791. From this work it appears, that the lazaretto of Venice was the earliest, and that the rules and tariffs of the other lazarettos in Europe were copied from it. The health-office in that city, by which the lazaretto is conducted, was instituted by a decree of the senate in 1484, during a time of pestilence.

In most commercial ports at present, the practice is, in case the incoming ship has not a clean bill of health, to place the ship itself in quarantine, that is, to prevent any intercourse with the shore, or with any other vessel, till it is clearly ascertained that there is no infectious disease on board. In England and some other countries, the doubts that have been thrown on the theory of contagion have relaxed the strict observance of these precautions; and lazarettos are falling out of use. [QUARANTINE.]

LEAD (Pb, from the Latin *plumbum*). This well-known metal has been in use from the very earliest times; it is frequently mentioned in the books of Moses, and Pliny describes the manufacture of leaden pipes. The alchemists called it *Saturn* (♄), first, because they thought it the oldest of the seven then known metals, and it might therefore be compared to Saturn, who was supposed to be the father of the gods; and second, from its power of dissolving other metals it was further likened to Saturn, who, according to fabulous history, was in the habit of devouring his own children.

With a few very rare exceptions, lead is never found native or in the metallic state. Its ores are numerous [LEAD, in NAT. HIST. DIV.], but it is chiefly from that known as *galena*, or sulphide of lead, that the metal is obtained. This ore contains from 75 to 83 per cent. of lead, according to its purity.

Lead crystallises in regular octohedra, and sometimes in four-sided

pyramids, but as usually obtained—by allowing a quantity of melted lead slowly to cool till the external part has solidified, then boring a hole through the crust and pouring out the still fluid metal from the interior, on the sides of which the crystals will be found—they present a fern-like appearance, somewhat similar to the form in which chloride of ammonium crystallises. By repeated melting in a vessel to which air has access, lead becomes more and more brittle, owing to its dissolving a portion of the oxide that forms on its surface; this may be prevented by covering it with a layer of charcoal; if already slightly oxidised it may be re-softened by well agitating it with charcoal. Lead boils at a white heat, and even at a red heat begins to volatilise. Cold hydrochloric or sulphuric acids have no action upon it, and at a boiling temperature dissolve only a small portion. Nitric acid, especially when rather dilute, converts it into nitrate of lead with evolution of binoxide of nitrogen. Acetic acid in the presence of air rapidly attacks it. [LEAD MANUFACTURE *white lead*.] Sulphate of lime and moisture also quickly corrode lead, hence in making cisterns and roofing houses, contact of the metal with plaster of Paris, &c., should be avoided. The alkalies appear to have little or no action upon lead.

Lead is soft, easily taking impressions, of a bluish-white colour, and not possessed of much ductility or tenacity. It melts at 620° Fahr., and at the moment of solidification contracts considerably, so that it is not well adapted for taking castings.

The equivalent of lead is 103.57, and its specific gravity 11.44.

A freshly cut surface of lead has a high metallic lustre, and this is retained if the metal be preserved in a hermetically sealed tube filled with perfectly dried air, or in a similar tube filled with water freed from all traces of air by long boiling. If the air, however, contain vapour of water, as is always the case under ordinary circumstances, then the bright surface rapidly tarnishes owing to the formation of a film of oxide. Pure water also in contact with air very rapidly and extensively acts upon lead, oxide is formed, carbonic acid is absorbed, and in a short time the metal becomes transformed into a white, flaky powder, composed of hydrated oxide and carbonate of lead (PbO , $\text{HO} + \text{PbO}$, CO_2). A very moist atmosphere produces the same result, though, of course, much more slowly; moreover, the hydrated basic carbonate produced is ultimately converted into anhydrous protocarbonate, owing to the replacement of the water of hydration by the carbonic acid of the atmosphere. An old leaden coffin, examined by Tuson ('Phil. Mag.,' April, 1860), was found to have been nearly all changed into this condition, 93 per cent. of it being pure anhydrous carbonate of lead (PbO , CO_2).

Compounds of Lead.

Lead and oxygen form four oxides, namely:—

- | | |
|--------------------------------|-------------------------------|
| 1. Din oxide of lead | Pb_2O |
| 2. Protoxide of lead | PbO |
| 3. Red lead | $x \text{ PbO}, \text{PbO}_2$ |
| 4. Bin oxide of lead | PbO_2 |

1. *Din oxide of lead* (Pb_2O), *suboxide of lead*, is a black powder obtained by cautiously heating oxalate of lead in a retort from which air is excluded. It is an unimportant oxide.

2. *Protoxide of lead* (PbO). *Litharge*. *Massicot*. The fused oxide that is produced in the process of cupellation, already described in treating of the purification of lead, is the protoxide. On cooling, it solidifies into a mass of reddish-yellow scales, and is known in the arts under the name of *litharge*. When ground it is used as a pigment by painters and decorators, also in the manufacture of acetate of lead, and sometimes enters into the composition of glazes used at glass-works and potteries. *Massicot* is protoxide of lead that has not undergone fusion. It is produced in making red lead.

The *hydrated oxide* ($x \text{ PbO}, \text{HO}$) falls as a white precipitate on adding an alkali to an aqueous solution of a lead salt. It is soluble in solutions of the fixed alkalis, compounds being thereby formed that sometimes are called *plumbites*. When heated it loses water, and yellow anhydrous protoxide remains.

Protoxide of lead is a powerful base, forming with acids *salts of the protoxide*. It has a great tendency to form basic salts.

3. *Red-lead* (*Minium*). This compound usually contains $\text{Pb}_3\text{O}_4 = 2\text{PbO} + \text{PbO}_2$, but sometimes has the composition Pb_2O_3 , and occasionally Pb_4O_5 ; in fact it may be looked upon as a compound of bin oxide of lead with one, two, or three equivalents of protoxide. All three varieties are of a brilliant red colour. Red lead is largely used as a pigment by the painter and the paper-stainer, and by the glass-manufacturer. [GLASS.] For the preparation of red lead, see LEAD MANUFACTURE.

4. *Bin oxide of lead* (PbO_2) is usually prepared by digesting red-lead in boiling nitric acid, whereby the protoxide is dissolved out, and the bin oxide remains as a *puce-coloured* powder. When fused with alkalis it forms crystallisable salts, called *plumbates*. The potash salt contains $\text{KO}, \text{PbO}_2, 3\text{Aq}$.

Lead and Phosphorus form a somewhat indefinite *phosphide*. It is unimportant.

Lead and Sulphur form *disulphide of lead*, Pb_2S , and *protosulphide* (PbS), obtained as a black precipitate on passing sulphuretted hydrogen through a solution of a salt of lead. The protosulphide occurs native under the name of *galena*; it has already been de-

scribed at the commencement of this article, and also in NAT. HIST. DIV., under LEAD.

Lead and Iodine form one combination, the *protoiodide of lead* (PbI). It falls as a bright yellow powder on mixing solutions of iodide of potassium and acetate of lead. It is slightly soluble in cold water, but much more so in hot water, from which solution it separates out on cooling in brilliant yellow silky scales.

Several *oxyiodides* of lead also exist.

Lead and Bromine form *protobromide of lead* (PbBr), a white precipitate resulting from the mixture of solutions of an alkaline bromide and a lead salt. From solution in hot water it separates out in white shining needles.

Lead and Chlorine form

Protochloride of lead (PbCl), *chloride of lead*. It is best prepared by precipitating nitrate of lead with chloride of sodium; it always, however, falls as a white powder when hydrochloric acid or a soluble chloride is added to an aqueous solution of a lead salt. Chloride of lead is soluble in boiling water to the extent of 3 per cent., depositing again on cooling in beautiful white silky needles. On the application of heat to it in the dry state it readily fuses, and solidifies on cooling to a semi-transparent mass termed *horn-lead*.

The *oxychlorides of lead* are numerous. One occurs native (PbCl_2PbO) [LEAD, *Berzelite*, in NAT. HIST. DIV.] at the Mendip Hills, in Somersetshire, and is hence frequently called *Mendipite*. Another, the subject of a patent, and used as a substitute for white lead, is made by acting upon galena with hydrochloric acid, dissolving the chloride of lead thus produced in hot water, and precipitating with sufficient lime water to remove one half only of the chlorine. The re-action is as follows:—

Cassel or Turner's yellow is an oxychloride of lead, much used as a pigment. It is prepared by heating chloride of ammonium with ten times its weight of litharge.

Fluorine and Lead form a white sparingly soluble *fluoride of lead* (PbF_2).

Salts of Protoxide of Lead.

Carbonate of Lead (PbO, CO_2). This compound is precipitated as a white powder whenever solutions of an alkaline carbonate and a lead salt are mixed together. It is insoluble in water, but easily soluble in nitric or hydrochloric acids.

White-lead, as it occurs in commerce, is generally basic carbonate of lead, containing about 7 per cent. of linseed oil. It is also met with unmixed with oil, and is then in the form of a heavy, white, amorphous powder, technically termed *dry white-lead*. White-lead may, however, as already indicated, be an oxychloride of lead, or even a neutral carbonate, and is often adulterated with sulphate of baryta, sulphate of lime, and carbonate of lime.

The old *Dutch method* of manufacturing white-lead consisted in suspending thin sheets of lead in long wooden boxes, at the bottom of which was weak acetic acid. See LEAD MANUFACTURE. The boxes were placed in a close stove-room, were either surrounded with horse-dung or had wine-lees put into them, and were subjected to a temperature of 85° to 90° for about a fortnight.

The changes which take place in this process may be shortly stated as follows. The spent tan, or horse-dung, or wine-lees, slowly decompose, generating heat, and evolving carbonic acid. The heat volatilises the acetic acid, and this, with the oxygen of the atmosphere, forms with the metal a basic acetate of the oxide of lead. The carbonic acid derived from the eremacausis of the organic matter decomposes this basic acetate, forming carbonate of lead and neutral acetate; the latter soon becomes basic again, and the same decomposition goes on over and over again, till the metal is entirely converted into basic carbonate.

Phosphates of lead.—The alkaline triphosphates, biphosphates, and monophosphates, give white precipitates with aqueous solution of acetate or other lead salt. They are all soluble in nitric acid, and have a composition corresponding to the alkaline phosphate that precipitated them. A *chlorophosphate of lead* ($3(3\text{PbO}, \text{PO}_5) + \text{PbCl}$) is found native. [LEAD, *pyromorphite*, in NAT. HIST. DIV.]

Sulphate of lead (PbO, SO_3) also occurs native. [LEAD, *anglesite*, in NAT. HIST. DIV.] It is formed as a white precipitate on adding sulphuric acid or a sulphate to a lead salt. It is a heavy powder, soluble to a greater or less extent in ammoniacal salts and in hyposulphite of soda. It is also slightly soluble in strong nitric or sulphuric acids: commercial sulphuric acid generally contains sulphate of lead as an impurity from the chambers in which it is prepared; dilution with water precipitates it.

Nitrates of lead are four:—

Sexbasic nitrate of lead . . .	$6\text{PbO}, \text{NO}_5 + \text{Aq}$
Trinitrate	$2(3\text{PbO}, \text{NO}_5) + 3\text{Aq}$
Dinitrate	$2\text{PbO}, \text{NO}_5 + \text{Aq}$
Mononitrate	PbO, NO_5

The last, or ordinary *nitrate of lead* is the only one of importance. It is readily made by dissolving oxide of lead in diluted nitric acid. On evaporating the solution it crystallises out in more or less opaque octohedra. It is soluble in eight times its weight of cold water; paper

or tinder saturated with the solution and dried is thereby rendered exceedingly inflammable.

Hyponitrates ($x\text{PbO}, \text{NO}_5$) and *nitrites* ($x\text{PbO}, \text{NO}_3$) of lead are formed when metallic lead is boiled with nitrate of lead. The strength of the solution and the extent of ebullition determines which of these is produced. They are all more or less crystalline.

Borates of lead result when boracic acid is fused with oxide of lead. One of them enters into the composition of Faraday's optical glass.

Silicate of lead is abundantly formed in the manufacture of flint glass. [GLASS.]

Tungstate of lead occurs native. [LEAD, in NAT. HIST. DIV.] It forms when ground up with oil a pigment resembling white lead.

Chromates of lead.—The two principal are (1) *neutral chromate*, PbO, CrO_3 , and (2) *dichromate* ($2\text{PbO}, \text{CrO}_3$).

1. *Chromate of lead*, or *chrome yellow*, occurs under many different names. [COLOURING MATTERS.] It is obtained on adding a clear solution of neutral chromate of potash, soda, or lime, to a solution of nitrate or acetate of lead, well washing the precipitate and drying it out of any possible contact of sulphuretted hydrogen.

2. *Dichromate of lead*, or *Orange chrome*.—It is made by boiling white lead in a solution of bichromate of potash, or by fusing yellow chrome with five times its weight of nitre, and well washing the product.

For a description of the details necessary to be attended to for the production of *lead chromes* of various shades, see a paper in the 'Pharmaceutical Journal,' vol. xv., pp. 66 and 69.

Tartrate of lead ($2\text{PbO}, \text{C}_4\text{H}_4\text{O}_{10}$).—Precipitate acetate of lead dissolved in water with half its weight of tartaric acid, and wash and dry the precipitate.

When tartrate of lead is heated in a closed tube it is decomposed, white vapours are evolved, and a mixture of metallic lead and carbon remain in an exceedingly minute state of division. On being thrown out into the air the mixture takes fire spontaneously, and is commonly known as the *lead pyrophorous*.

Acetates of lead. [ACETATE.]

Alloys of lead. [BRITANNIA METAL; PEWTER; SOLDER; SHOT; TYPE-METAL.]

Tests for lead.—This metal is recognised in solution by the yellow precipitate of chromate with chromate of potash; white, soluble in excess with the alkalis; white, insoluble with sulphuric acid or a sulphate. The formation of iodide of lead by adding a few drops of iodide of potassium solution, is perhaps the most characteristic test for lead, as the precipitate dissolves when heated, and is deposited again on cooling in the well-known beautiful golden yellow scales. Sulphuretted hydrogen is, however, the most delicate test for lead. The formation of arborescent crystals of lead, by suspending a piece of zinc in a solution of acetate of lead, is an illustration of how one metal, having more powerful affinities than another, becomes a test for the latter. Thus *zinc* is a test for lead.

Estimation of lead.—This is generally effected in the state of sulphate, which contains 68.31 per cent. of metal.

LEAD, MEDICAL PROPERTIES OF. In a purely metallic state, lead produces no action on the human system, except such as arises from its mechanical properties; but as soon as it has become oxidised, it can combine with the contents of the stomach, and produce different effects, according to the nature of the substances it meets with, hence even a leaden bullet, swallowed, has given rise to the symptoms characteristic of the presence of lead. "In whatever form lead is habitually applied to the body, it is apt to bring on the train of peculiar symptoms: the inhalation of its fumes, the habitual contact of any of its compounds with the skin, the prolonged use of them internally as medicines, or externally as ointments and lotions, and the accidental introduction of them for a length of time, with the food, may, sooner or later, equally induce *colica pictonum*, or painters' colic. Of all exposures none is more rapid or certain than breathing the vapours or dust of the preparations of lead." (Christison.) Thus the workmen at Lead Hills in Lanarkshire are stated never to have the lead-colic until they work at the smelting furnaces. The action of lead on the human frame differs greatly according to the kind of preparation of lead, the quantity employed, the length of time or frequency of exposure to it, and the channel of its introduction into the body, and idiosyncrasy of the individual. If injected into a vein, acetate of lead, even in small dose, will produce almost immediate effects; while if taken into the stomach it is much slower, and a considerable quantity is requisite to produce serious consequences. In the latter instance the effects are both local and remote: "One class of symptoms indicates inflammation of the alimentary canal; another, spasm of its muscles; and a third, injury of the nervous system, sometimes apoplexy; more commonly palsy, and that almost always partial and incomplete. Each of these classes of symptoms may exist independently of the other two; but the last two are more commonly combined." (Christison *On Poisons*, p. 511.) The rapidity of action is also determined by the solubility of the preparation or salt of lead; while the degree of effect is also closely connected with the solubility, the more insoluble salts being nearly powerless—a circumstance which supplies a convenient mode of disarming the others of their virulence by converting them from soluble to insoluble salts. Fatal cases from poisoning by large quantities of the salts of lead are not numerous, as there is in general time to administer antidotes; but death from the slow and insidious introduc-

tion of lead into the system is of frequent occurrence. The principal source of these is the use of water or other fluids containing lead in solution, the intermixture of lead, as adulterations or accidentally, with articles of food, or handling preparations of lead in the daily business of artisans, such as painters, plumbers, &c.

The danger of using water from leaden pipes or cisterns was known even to the Romans, "among whom, however, the reservoirs were either of marble or cement, or of copper lined with tin, or of other metals more precious" (Alderson); nevertheless, pipes and cisterns of lead are still extensively used, and the rarity of any fatal results shows that the risk has been overrated. This is sufficiently explained by the protecting power of the insoluble salts of lead, formed by the action of the ingredients of the water on the lead, which hinders the subsequent supplies of water from coming in contact with the metal. [LEAD, Col. 144.] No water should ever be drunk or employed for culinary purposes out of new cisterns; but water should be allowed to stand in them for some time without being renewed, for only after a crust has been formed does the water become safe; or to expedite this, a little phosphate of soda or iodide of potassium may be added, or a few drops of sulphuric acid may be used. The expedient of Mr. Chatterton of an inside lining of gutta percha to pipes or cisterns removes all danger. The lid or cover of cisterns should never be made of lead, as the vapour which condenses on it possesses all the solvent power of distilled water. It is also unsafe to use water which has flowed over leaden roofs, more particularly in towns, as the surface of the lead is almost invariably coated with some soluble salt; this Dr. Medlock attributes to nitrous acid being present in the atmosphere of towns. It is, however, an error to attribute all the changes which lead used for roofs or cisterns undergoes solely to the corrosive power of water. (See case by Dr. Wall, quoted in Christison, p. 488, edition 1836.) The holes with which the lead is often riddled are caused by the larva of an insect, the *Callidium bajulus*, in the stomach of which lead is often found. (Kirby and Spence's *Entomology*, i., p. 235.) The *Urocerus juvencus*, Linn. and *Anobium striatum*, likewise perforate lead.

Perfumed distilled waters, such as orange-flower water, often contain lead in solution, derived from the solder cementing the copper vessels in which these are imported, whenever lead has been employed instead of tin solder.

No kind of adulteration or impregnation with lead, from accident or ignorance, is more common than that of wine or cyder. Even a single shot of lead left by accident in a bottle after cleaning has produced severe colic; and the more extensive use of the salts of lead to fine wines, as it is termed, that is, to remove their acid taste and make them sweet, has occasioned most serious consequences. In the cyder-presses, and in the worms of stills, lead was formerly employed, but it is now nearly banished from use. Lead is sometimes employed either ignorantly or fraudulently, to render tart and bad wines marketable. The lead, if present, may be detected by appropriate tests, among others by *Hahnemann's wine test*, made by putting into a small phial 16 grains of sulphuret of lime, prepared in the dry way, and 20 grains of cream of tartar. The phial is to be filled with water, well corked, and occasionally shaken for the space of ten minutes. When the powder has subsided, the clear liquor is to be decanted off, and preserved in a well stopped bottle. This liquor, when fresh prepared, discovers lead by causing a dark-coloured precipitate. Domestic and British wines, the nature of the fruit used in preparing them unavoidably causing them to be more acid than those prepared from the grape, are most likely to be impregnated with lead, particularly as in some cookery books it is ignorantly recommended to sweeten them.

Another important source of impregnation of articles of food with lead is connected with the use of earthenware glazed with lead. Anything containing vegetable acids, if kept in such vessels, will act on the lead, and may produce poisonous effects. Even milk cannot be kept with safety in leaden-glazed dishes. For all preserves, jellies, &c., Bristol-ware, which is glazed with salt, should be employed. Nothing can be more dangerous than to keep vinegar in leaden bottles, or even in jars glazed with lead. The use of acetate or sugar of lead to clarify syrups or honey, or to render brandy pale, is to be avoided. Rum, hollands, and geneva are occasionally adulterated with lead, and cause extensive evil. Colouring cheese with red lead is equally hazardous.

Nitrate of lead in solution in water—1 part of nitrate of lead to 10 parts of water, termed Ledoyen's disinfectant—is useful put into night-tables, as a destroyer of sulphuretted hydrogen and sulphuret of ammonium. But it is inferior to manganate of potash. [DISINFECTANTS.]

In small medicinal doses acetate of lead, which is almost the only salt administered internally, produces a direct action on the secretions of the stomach, combining with the albumen, and forming compounds which are for the most part insoluble in water and acids, but occasionally forming other compounds which are soluble by the addition of a small quantity of acetic, hydrochloric, or lactic acid. As these acids exist in variable quantities and under different circumstances, the degree and kind of action will be different, according as the lead is dissolved and conveyed to distant organs, or as it remains nearly undissolved and accumulated on the mucous membrane. In the greater number of cases it is very slowly introduced into the circulation. Even

a considerable dose may display merely local effects, exciting irritation and inflammation; though these are sometimes followed by colic, convulsions, coma, or local palsy, and amaurosis or deafness.

By a repetition of small doses the secretion of most mucous surfaces is diminished, and constipation occurs; the heart's action is reduced, and the calibre of the arteries is lessened and exhalation checked: if hæmorrhage should exist, that generally stops. Acetate of lead thus appears to be decidedly sedative and astringent. It manifests its sedative effect even when applied externally, and lessens discharges from ulcers, though its application to these is not always safe. Even white-lead (carbonate of lead) ointment applied to ulcers has proved fatal.

Acetate of lead should always be dissolved in distilled, not in common water. It is a most improper application to inflamed cornea whenever that is ulcerated, as it forms a white compound which is apt to get imbedded in the cornea.

The diseases in which it proves most useful are increased discharges, either from mucous surfaces or in hæmorrhages. Vinegar should always be given at the same time. In diarrhoea, dysentery, but, above all, in cholera, when combined with opium, it is a most efficacious remedy (Dr. Graves, in 'Medical Gazette,' Oct. 14, 1837); in fevers attended with diarrhoea it is also useful. Combined with opium on which boiling water has been poured, it forms a most grateful wash to erysipelatous and other inflamed surfaces. In all cases care must be observed in its use. In poisoning by acetate of lead or by litharge, the best antidotes are sulphate of soda (Glauber salts), sulphate of magnesia (Epsom salts), or alum, to decompose or form an insoluble compound, and afterwards the stomach-pump may be used, or emetics of sulphate of zinc may be given. [PAINTERS' COLIC.]

The whole subject of the action of lead upon the human system has been very fully treated by Dr. James Alderson, in his 'Lumleian Lectures,' printed in the 2nd vol. of the 'Lancet,' for 1852, p. 72, &c.

LEAD MANUFACTURE. Lead (French, *plomb*; Italian, *plombo*; Spanish, *plomo*; Portuguese, *chumbo* (all from the Latin *plumbum*); German, *blei*; Dutch, *loot*; Russ., *svinetz*) was known and used by the Greeks and Romans for various purposes; among others, it was employed for pipes to convey water, just as it is now. The lead-mines of Britain were worked by the Romans, of which we have evidence in the pigs of lead preserved in the British Museum, and stamped with the names of the emperors Domitian and Hadrian. The early writers in this country, when speaking of the metals, are so confused, that it is by no means certain of which of them they are treating. This confusion is so great, that Sir George Harrison, when writing in exposition of the stannary laws of England, says, "in a liberal construction, copper is tin." The framers and early expounders of those laws fell into some strange mistakes regarding even the nature of particular metals: these mistakes affected lead as well as other metals.

The principal lead-mines in Great Britain are in Cornwall, Devonshire, Somersetshire, Derbyshire, Durham, Lancashire, Cumberland, Westmoreland, Shropshire, Flintshire, Denbighshire, Merionethshire, and Montgomeryshire; in Scotland, at the Lead Hills on the borders of Dumfriesshire and Lanarkshire, in Ayrshire, and in Argyllshire. In Ireland, lead is found in the counties of Armagh, Wexford, Wicklow, Waterford, Clare, and Down. No certain account of the produce has ever been obtained: the proprietors or occupiers of the principal mines declining, from prudential motives, to give detailed statements to that effect. In recent years, however, approximate estimates have been made, which we shall notice in a later paragraph.

The ore of lead, when extracted from the mine, is called *galena*, and is combined with various earthy matters. This galena, an impure sulphide or sulphuret, is the most important among the ores of lead; it contains 86 parts of lead to 14 of sulphur. Of other ores of lead, very few are used as sources of the metal. The mining operations need not be specially described here. [MINING.]

The first processes subsequent to its extraction are those of crushing or pounding and washing the ore, in order to separate as far as possible by mechanical means the impurities from the metal. The ore is then smelted, sometimes in a common smelting-furnace and sometimes in a reverberatory furnace, both of which are very similar in form and construction to the furnaces used for melting and puddling iron. [IRON MANUFACTURE.] When the fusion has been continued long enough to cause the expulsion of the sulphur contained in the ore, and the separation of the earthy matter in the form of scoria, the latter, which from its smaller specific gravity floats on the melted metal, is removed from the furnace through an aperture provided for the purpose; and the lead is allowed to run into a large iron pan, from which it is ladled into cast-iron moulds. It then constitutes what is called *pig-lead*. The scoria still contains a portion of lead, and is subjected to the heat of another furnace, called a slag-hearth, for its separation, which occurs upon its fusion; the metal then falls into a cavity, whence it is run and also cast into pigs.

Before tracing the lead to its employment in manufactures, we must notice a very remarkable reward which ingenuity has reaped. The pig-lead always contains more or less of silver. The proportion is sometimes exceedingly minute, being not more than one ounce per ton in the metal raised in Derbyshire and Shropshire, while in every ton of the lead from Devon and Cornwall there is found from 20 to 40 ounces of silver: in some instances very much more. The produce of other

mineral contains the more precious metal in various proportions between these two extremes. The extraction of the silver is always performed when it exists in a proportion sufficient to pay the expense of the process, which varies in different localities according to the cost of fuel. The process of extraction, which is called *refining*, depends upon the well-known circumstance that lead, when heated to redness, absorbs a large portion of oxygen from the air, and is converted into an oxide; while silver does not undergo any such change, but retains its metallic form at almost any temperature. A *cupel*, which is a shallow dish of adequate dimension, is filled with a mixture of burnt bones and fern ashes pressed down, upon which the lead to be refined is placed in the furnace. As soon as the lead is melted, a blast of air, introduced by the usual means, is made to play forcibly upon the surface. In a short time a crust of yellow oxide is formed, which is driven away as fast as it appears to the opposite side of the furnace, until all or nearly all the lead has been thus converted to an oxide. The silver, which remains behind, is still combined with some portion of lead, and must be subjected to a second process similar to that here described, in order to liberate it in sufficient purity. The litharge, into which the lead has been thus converted, is easily restored to its metallic state by again heating it in a furnace in combination with carbonaceous matter, to which it gives up its oxygen.

This process, although valuable to a certain extent, is defective. There is a considerable waste of material when thus treated, varying according to the quality of the lead. The oxide is very volatile at high temperatures; and so much of it escapes in a vaporous form during the process of refining, that the difference of weight before and after its completion is on the average about two-fifteenths. Under these circumstances, a very beautiful process was brought forward in 1829 by the late Mr. Hugh Lee Pattinson. As a poor boy employed in a small chemist's shop at Alston, he became familiar with the operations at the lead-works in the vicinity of that town; and in after years this experience led him to the *crystallising* method of extracting silver from lead. Having observed that, in a mass of melted lead, crystals were formed as the temperature was diminished below the point of fusion, Mr. Pattinson conceived that these crystals might be more homogeneous, and would consequently be united with a smaller proportion of silver, than the remaining uncrystallised mass. This idea, proving upon experiment to be correct, has been made practically useful by subjecting the lead to repeated processes of crystallisation by means of a simple apparatus. This consists of a series of hemispherical iron pots, each capable of holding five tons of lead, ranged side by side, and furnished with separate fireplaces. The mode of operation is as follows:—One of the pots is charged with lead, and when this is melted, the surface is skimmed in order to remove such impurities as are thrown up. The fire is then withdrawn, and the lead is suffered to cool gradually. When the process of crystallisation begins, the crystals are withdrawn by means of ladles with perforations to allow the uncrystallised part to run through. These crystals are transferred to the second pot, where they undergo a second melting and crystallisation, and subsequently a third in another pot. This is continued until the crystals collected are found to contain no more than from 10 to 15 dwts. of silver per ton, and are consequently melted and cast into pigs for sale as refined lead. The process here described is repeated with the remaining portion of the lead until it is so rich in silver as to contain from 300 to 500 ounces per ton, after which the silver is extracted by the old process of cupellation. As the proportion of lead to which the cupelling process is applied does not exceed one-twentieth of the whole quantity of metal, the loss is diminished in a like proportion; by which means the expense of the extraction of silver is so far economised, that it will answer to apply the process to lead which originally contains any proportion greater than three ounces of silver to the ton.

There is much that is interesting in this process. Not only is there a great saving of lead, but the silver extracted is considerable in amount. Shortly after Mr. Pattinson's death, in 1858, it was stated that his crystallising process has been the means of adding 200,000 ounces to the silver annually produced or extracted from English ores.

We shall now notice a few of the principal manufactures connected immediately with this metal—such as *sheet lead*, *lead pipes*, *lead shot*, *litharge*, *red lead*, and *white lead*.

To make *sheet lead*, the pigs are brought to a state of fusion in a large pot or cistern, near which is placed the table on which the sheet is to be cast. These pigs are about three feet long by six inches wide, and weigh about 170 pounds each. Two methods of making sheet lead are adopted, *casting* and *rolling*. In the casting method, the table, which is usually from 18 to 20 feet long and six feet wide, was formerly made of wood; and indeed wooden tables are still frequently used, but in many works cast-iron has been substituted. The wooden table has its surface protected by a layer of fine sand, which is wetted and spread evenly and firmly over it before the melted lead is poured on. To prevent the lead from running over the sides a ledge is provided, two or three inches thick, and two inches high, which forms the margin of the table. An instrument called a *strike* is also provided to regulate the thickness of the sheet, and to spread the melted metal evenly over the table. This strike, which is made wider than the table, rests by its two ends on the ledges; the size or diameter of the part within those ledges being adjusted according to the intended thickness of the

sheet, which will be equal to the distance between the lower side of the strike and the layer of sand. In casting the sheet, the fused metal is taken from the cistern with an iron ladle, and put into a triangular shaped iron shovel or peel, placed at the head of the table, which peel being raised so as to pour out the lead upon the table, the strike is brought into use to spread it evenly over the whole surface; the surplus, if any, falling into a vessel placed for its reception at the foot of the table. Sheet-lead of different thicknesses is described by those who use it as being of so many pounds weight to the superficial square foot. The usual kinds for covering roofs and gutters vary from about $\frac{1}{16}$ th to $\frac{1}{4}$ th of an inch in thickness, with a weight varying from about 6 pounds to 12 pounds per square foot. In the method of making sheet lead by *rolling*, the lead is first melted in a very large vessel which will contain six tons; from this, when freed from all impurities, it is allowed to flow through an opened valve into a cast-iron frame called

Lead Foundry.

the mould, about six feet square by six inches deep. The lead, thus cast into a thick block, is, when cold, lifted out of the mould by a crane, and placed in the lead mill. This mill consists of two ponderous

Lead Rolling Mill.

iron rollers, between which the lead is made to pass by steam power, and an iron frame with wooden rollers to facilitate the movements of the lead; the passage is repeatedly made, until the metal is brought down to the required thickness. For some kinds of sheet-lead the successive rollings or millings amount to as many as eight hundred, by which the length is increased from six feet to four hundred feet.

Lead pipes are sometimes made, when great exactness of shape is not required, by bending a length of sheet-lead of the necessary width over a mandrel, and soldering the edges together. The more usual method of manufacture, however, is by casting and drawing. The casting-box employed is an iron cylinder made in two parts, and put together longitudinally with flanges; inside of this cylinder is placed an iron rod or core, which is so fixed as to be concentric with the cylinder without touching it; a space is thus left, into which the melted lead is poured. When this is set, the core is removed and the cylinder opened, so as to withdraw the pipe. The pipe being in its present state

much thicker than is needed, must be lengthened, while its substance is reduced, by drawing it through a succession of holes in steel plates, diminishing gradually in diameter, similarly to the method

Drawing Bench for Lead Pipe.

Lead shot is made by pouring the melted metal from a great height into water. This process was invented in 1782 by a workman named Watts, residing at Bristol; who is said to have conceived the idea in a dream, and to have proved its practicability by pouring some melted lead from the tower of the church of St. Mary Redcliffe at Bristol. Having secured the invention by a patent, he sold it to parties possessed of adequate capital; and the patent having long since expired, the process is now in common use. In order to give to the lead the quality of assuming a more perfectly globular form in cooling, the metal is previously alloyed with 2 per cent. of arsenic, or with a small quantity of mercury, which latter is used in order to obviate an objection caused by the poisonous quality of arsenic. Shot formed by granulation are made in a high tower, in the top of which the melting-room is built. Close to the furnace is placed a large colander or perforated plate, into which a portion (determined by experiment) of the scoria produced in melting the metal is placed; after which the metal is ladled into it. Being somewhat detained by the scoria, the lead is partially cooled and divided into separate portions, which pass through the colander in the form of globules; these globules follow in such rapid succession as to have the appearance, to a cursory observer, of a continued stream. The globules fall into a vessel of water placed on the lower floor of the tower. Near Newcastle, deserted coal-pits are used instead of lofty towers. At New York, lead shot are made in a building of moderate height, with a blast of air constantly rushing upwards; this quickens the cooling, and the shot are said to comprise a smaller number of defective globules. Under any system of manufacture, however, the shot are of various sizes, and a small proportion are imperfect as regards sphericity. Having been perfectly dried by artificial heat, they are sorted according to their sizes by means of a series of sieves, the meshes of which have different degrees of fineness. A sieve having the smallest mesh is first used, that the smallest sized shot may pass through and be collected. What remain are transferred to the sieve next in fineness, to separate shot of the second size, and so on in succession. The process of separating the imperfect shot is very simple. A shallow wooden tray is suspended by cords from the ceiling of the room, and into this a certain quantity of shot is put. By raising one end of the tray, and giving it a motion from side to side, the shot will roll about: such as are perfectly spherical finding their way off the tray into a reservoir placed at its lowest side; while those which are of imperfect form run against and are detained by the sides of the tray, so that they can be collected in a separate vessel after the perfect shot have all run off. A very delicately constructed machine is now used in some shot-works instead of this tray. The shot thus sorted are then polished by putting about half a ton together into an iron barrel which that quantity will nearly fill. By means of a rotary movement given to the barrel, the shot are made to rub against each other, and thus acquire a black colour and a lustrous appearance. The finished shot, varying from $\frac{1}{8}$ th to $\frac{1}{30}$ th of an inch in diameter, are finally tied up in bags.

Litharge, Red-lead, and White-lead are compounds, the chemical nature of which has been noticed in connection with the chemistry of lead; we treat here simply of a few manufacturing details. Litharge is produced in the act of cupellation for extracting the silver, already described. It is used in the making of flint-glass; and in preparing certain salts of lead which are employed in dyeing and calico-printing; or, when mixed with coal and heated in a furnace, it may be made to yield up its metallic element, which is then called *refined lead*. *Red-lead*, or minium, is made by the medium of a reverberatory furnace. The pigs of lead are melted in these furnaces, and while in a fluid state, the metal is raked and stirred by means of an apparatus suspended from a chain, and held by a workman. The stirring continues several hours, by which time the metal, through imbibing oxygen, has lost its fluidity, its whitish colour, and its metallic lustre, and has become a grayish-yellow powder. A further process separates a small portion of unchanged lead from the powder, which then becomes a yellow pigment called *massicot*; and this massicot, by a second exposure to the reverberatory furnace, becomes converted into the still more useful pigment red lead. *White-lead* forms the basis of nearly all the pigments used by the house-painter. It is very unwholesome, giving rise to a disease called the *painter's colic* [PAINTER'S COLIC], and attempts have

adopted in drawing iron rods. The machinery employed for this process has at different times been much improved in its construction; so that it is now of rare occurrence to meet with an imperfect pipe.

frequently been made to supersede it by other substances, but it still remains the staple article of the trade. It is a carbonate of lead, and is produced in various ways; but the usual process in the Newcastle district is the following. In a large square room ashes are laid on the floor; then a thick layer of tanner's spent bark; then a series of earthen pots, each containing about a pint of vinegar; then a series of small plates of sheet-lead, covering the open mouths of the vinegar-pots; then a layer of boards; then a second layer of tan; then a second series of vinegar-pots, covered by a second series of leaden plates—and so on: until a pile 20 or 30 feet high is built up. The room thus filled often contains 10,000 or 12,000 pots of vinegar, covered by three or four tons of lead; and in a large factory there may be ten or a dozen of such rooms. The room is then closed, and is kept closed for many weeks. The tan gives forth heat enough to induce chemical action, and an intricate series of decompositions and re-compositions follow. The result is, that the lead combines with oxygen and carbonic acid to form a flaky white substance, which, after a few more processes, becomes *white-lead*—sold either as a dry earthy substance, or as a kind of thick paste ground up with linseed oil. The late Mr. Pattinson was among those who introduced substitutes for white-lead. One was an oxychloride, made from a solution of chloride of lead with a solution of lime, soda, or other alkali.

In the lead trade, the imports, which are only small, are almost wholly from Spain, the produce of exceedingly rich mines situated at Adra in Granada. The quantity furnished by these mines varies much; their greater or less produce has a great influence upon the price of lead in every market of the world; and at times has acted injuriously upon the mine-owners in this country. The home produce was about 78,000 tons of ore in 1848, yielding 55,000 tons of lead; and 97,000 tons of ore in 1857, yielding 69,000 tons of lead—the ratio being about 70 per cent. of lead in the ore. England produces three-fourths of all the lead ore raised in the United Kingdom. At the prices of 1857, the lead was worth about 1,500,000*l.*, besides the silver extracted from it. The Alston district, on the confines of Northumberland and Durham, yielded the largest return in 1857 (17,000 tons); but Cornwall gave the richest per-centage of silver, averaging 37 ounces to the ton. The imports of lead (pig and sheet) in 1858, were about 14,000 tons. The exports in the same year were about 20,000 tons; besides 6000 tons of white lead, red lead, and litharge.

LEAD-LINE. Ships are said to be *in soundings* when the sea bottom can be reached by a weight lowered from a ship with a line attached. Of late years the depths at which this can be conveniently done have increased in extent. Lead-lines are carried by every ship or vessel afloat, and are either called *hand lines* or *deep sea* (or “dip sea”) *lines*. The hand-lead weighs usually about 7 lbs., and its line varies in length from 20 to 35 fathoms, or sometimes 40 fathoms, being marked as follows:—

At 2 fathoms from the lead, with a strip of black leather.			
3	“	“	with ditto notched.
5	“	“	with a piece of white rag or bunting.
7	“	“	with a piece of red rag or bunting.
10	“	“	with a wide strap of leather with a hole in it.
13, 15, and 17,	as at	3, 5, and 7.	
20	“	“	a cord with two overhand knots.
25	“	“	a cord with a half knot.
30	“	“	a cord with three overhand knots.
35	“	“	a cord with a half knot.
40	“	“	a cord with four overhand knots.

The marked depths are called *marks*, the unmarked are called *deeps*. Hence we say “*by the mark seven*,” but “*by the deep nine*,” &c., and for portions of a fathom in shallow water we denote (say, for instance) $3\frac{1}{4}$ and $4\frac{1}{2}$, by the words “quarter less four” and “and a half four,” &c.

A good leadsman will swing the lead over his head and throw it well forward, so that it may reach the bottom by the time the ship's motion brings it abreast the gangway, when he dexterously feels the ground and gets his “cast,” and reads and sings the true depth. It is usual to have a hollow in the bottom of the lead filled with tallow, to which loose substances at the bottom adhere, and show the nature of the bed

of the sea; this alone frequently acquaints a mariner with his ship's position.

The heaving of the lead forms one of the most interesting, as it is often one of the most intensely exciting, of all nautical operations, and it is so important that the Board of Trade have attributed the loss of a large amount of life and property to a neglect of it. It has been the theme of heart-stirring song and the plaintive voice of the leadsman calling the depths with studied professional tone and precision, as he feels beneath him the distance of the hidden danger, still enchants the ear of the evening wanderer upon coasts along which the sailor stems his way. To those even who are ignorant of the nature of the operation of sounding, the peculiar harmony of the leadsman's song acts like a momentary spell upon the sense, and arrests the step until the last note expires, and the evening or night resumes its stillness.

LEAGUE, LEUCA, LEUGA, LEUVA, LEWEKE, &c., an itinerary measure, which in modern English always means the twentieth part of a degree of latitude, or three of what are called geographical miles, each of which is the sixtieth part of a degree. The variation of the degrees of latitude is not sufficient to make this measure sensibly incorrect for nautical purposes; and the league of our sailors may be described and easily remembered as 3.456 statute miles of 1760 yards each. The same marine league is used by the French and other nations; besides which, the French have among their itinerary land measures two distinct leagues (or *lieues*, in some of the provinces *lègues*), the first of 2000 toises, or 2.42 English statute miles, which is the legal posting measure; the second of 25 to the degree, or 2.77 English miles. These are selected from among the French measures for their celebrity, and not as being the only ones; for before the Revolution there was no legal itinerary measure, and the length of the league varied from province to province. (Paueton.)

The *leuca* of the ancient English law writers is necessary to be determined before the rights given by many charters can be defined; but unfortunately the length of this measure is enveloped in utter confusion. The modern lawyers, we believe, evade the question by setting it down as a mile; thus the legal minimum distance between two markets, which was certainly 7 *leucæ*, is now called 7 miles. We shall, in the present article, collect a few testimonies on the length of the *leuca*, and must leave the reader to form the best opinion which he can upon the varying presumptions which they afford.

By citations in Ducange, Paueton, &c., it appears that Hesychius distinctly describes the *λεῦγη*,* and Jerome, Jornandes, &c., the *leuca* (stated by Camden to be derived from the Celtic *leach*, a stone) as a Gaulish measure; and the original Gallic league was set down by the Romans as a mile and a half of their own measure, which was in all probability a rough estimation, first used in the Itinerary of Antoninus. In that work the distances from place to place in Gaul are frequently given in leagues (always in whole numbers), which are in every instance reduced to Roman miles at the rate of a mile and a half to each league. (See also Amm. Marcell., xvi., c. 12.) Hence, taking the Roman foot at 11.62 English inches (which is a mean between the most trustworthy measures) and the pace of 5 feet at 58.1 inches, the Roman mile of 1000 paces is 1614 English yards, and the *leuca* was therefore 2421 yards, subject to the error of the Roman estimation; or 1.376 modern English miles, with the same reservation.

This *leuca* in all probability was brought by the Normans into England. It is true that the Saxon charters of Ingulphus describe distances in *leucæ*; but the genuineness of these charters is now considered more than questionable, and perhaps this very circumstance is a presumption against them.

The evidence against the genuineness of the history of Ingulphus, when all put together, looks very strong. (Wright, 'Biog. Brit. Lit.,' Anglo-Norman period, p. 28.) There is nothing to set against it except our knowledge that the reaction against a work which has once been received, when suspicion of forgery arises, is strong and even bitter: a modified conclusion may possibly be arrived at in time. It must be remembered, also, that the same research which has thrown doubt upon Ingulphus has detected much tendency to Normanism in England even before the invasion by William: how much, is perhaps hardly known. It may therefore possibly be that the *leuca* was to some extent used in Saxon England.

The *leuca* soon began to vary in size. Ducange cites an old metrologist who speaks of two *leucæ*, the one legal, of 3000 paces, the other common, varying much in different countries. In the confusion incident to our subject, it will be worth while to remember that it was not uncommon, when a measure was found too short for convenience, to double it without altering its name: thus among the list of old coins (1540) given by John Dee, is found the *penny of two pence*. The registers of Battle Abbey (Sir H. Ellis) and the 'Monasticon Anglicanum' (Ducange) describe the *leuca* as containing 12 *quarantænæ*, or furlongs. Now the furlong (forty-long) is always 40 perches, and the perch, though varying much, yet was settled very early at 16½ feet. This gives a modern statute mile and a half to the *leuca*; so that a certain set of old authorities countenance the notion that the *leuca* was in their time very little more than that of the Gauls. It is not worth

* The reading in Hesychius is, *Λεύγη, μέτρον τι γάλακτος*. We do not know who made the correction *Γαλατικόν*, but this word or *Γαλάταις* is probably the right reading.

while to take into account any possible variations of the foot, since all the information we can obtain is too rough even to make the whole difference between the Roman and modern English foot of consequence.

The earlier statutes do not define the itinerary measures; confining themselves entirely to those by which land and goods were bought and sold. And the itinerary measures seem to have been on the increase, perhaps for the following reason: the jurisdiction of towns, monasteries, &c., was usually defined as extending a *leuca* or a given number of *leucæ* in every direction from their precincts, so that it became the interest of these powerful bodies to make the *leuca* as long as possible. The old French term *ban-lieu*, *banni-leuca*, or league of the edict or regulation, refers to the space over which jurisdiction was granted. Ingulphus, or his personator (for such a fact the two are almost equally good authorities), perhaps lets us a little into the secret when, speaking of his own monastery, he says, "Prudentissimi metatores, contra malitiam emulorum nostrorum piissimè providentes, potius plus quam minus ponere voluerunt." The same Ingulphus informs us that in his time the usual league was of 2000 paces, or 1.835 modern English miles, if the Roman pace be meant: but he adds that the English, adopting a Norman word to their own measure, frequently spoke of *leucæ* when they meant miles. But it may be questioned whether the mile and the *leuca* ever became interchangeable words in writings or charters, at least in England: in several Continental countries the term mile never became vernacular, and *miliare* is therefore translated by league.

There is sufficient evidence to show that, whatever the mile of a later date may have been, the *leuca* was generally two miles, though instances occur in which it is still described as 1500 paces. The following are extracts with which we have been favoured from manuscripts in the British Museum. In the registers of the monastery of Canterbury (of the 14th century) we have the following:—"Mensura unius pollicis incipit ex transverso radicum unguinum pollicis. Tres pollices unam palmam faciunt: quatuor palmi faciunt unum pedem. Pes et dimidium faciunt cubitum parvum: Sex parvi cubiti faciunt cubitum magnum. Quinque pedes faciunt passum unum. Centum viginti quinque passus faciunt stadium unum. Octo stadia faciunt unum miliar. Duo miliaria faciunt unam leucam." This gives a *leuca* of 10,000 feet. Again, in the same manuscript: "Memorandum quod virga communis continet xvi. pedes et dimid. videlicet quinque ulnæ et dimid. secundum standardum Regis. Idem xl. virgat. continent i. quarantenam. Item vii. quarantenæ et dimid. iii. virgat. et ii. palm. continent unum miliar. Item duo miliar. continent i. leucam." This gives a *leuca* of the same length. In a manuscript supposed to be of the time of Edward IV. we find "v. fote make a pase, and ther go viii. forelongs to a mile in Yngland, and ii. ynglysch myle make a ffrenshe leweke."

Bracton (Henry III.) and Fleta (Edward I.?) both assert (see the citations in Cowell, Comyns's 'Digest,' &c.) 6 leagues and half a league and the third part of a half (or 6½ leagues) as being the distance between two markets which do not injure each other; because 20 miles is a reasonable day's journey: now (both of them say) if the *dieta*, or day's work, be divided into three parts, the first is for going to the market, the second for business, and the third for returning. This appears to mean that no market should be established within a third of a day's journey of any one who is already within a third of a day's journey of the established market, so as to give him the option of going to either; that is, the two markets must be at least ⅔ of 20 miles apart, which being further described as 6½ leagues, shows that the *leuca* is 2 miles. This quotation is important, as establishing the meaning which the old law writers attached to the word.

It may then, we think, be confidently asserted, that the league, which began as a mile and a half (Roman), soon became lengthened, until it remained fixed at two of the miles of the day. It appears, also, that this length of 2 miles was a settled league at so early a period, that it is the measure of our oldest law writers, and of most of the oldest charters. It depends, therefore, upon the mile of the 13th and 14th centuries; and we must refer to the article MILE for the discussion of its absolute length. In order that matters of computation very nearly related may not be separated, we refer to that article some independent evidence on the length of the league, which makes no mention of the mile. We shall finish this article by stating our conviction that the length of the league or *leuca* was, in the time of the old law writers, very near, one way or the other, to two modern statute miles and nine-tenths of a mile: the old mile being to the modern statute mile in the proportion of 145 to 100.

LEAP YEAR, the name given to every fourth year of the Julian calendar, in which one additional day (a twenty-ninth day of February) is reckoned. This correction constitutes the distinction of the Julian calendar: the necessity for the Gregorian correction arises from the years being made a very little too long, one with another, by making them consist of 365½ days each, as is done when a day is added to each fourth year. The Gregorian correction is made by omitting three leap years in four centuries, and it is settled that the common years, which would otherwise be leap years, shall be those which terminate centuries in which the first pair of figures is not divisible by four. Thus the years 1800 and 1900 are not leap years, but 2000 is leap year; 2100, 2200, 2300 are not leap years, but 2400 is leap year. [KALENDAR.]

LEASE. A lease, or letting, is sometimes called a demise (demissio.) It is sometimes said that Lease is from the Latin "locatio;" but as the verb which corresponds to the noun Lease is Let, it seems that the word Lease is the noun which corresponds to the verb Let. The verb let is akin to the French "laisser," and the German "lassen."

He who lets land is called the lessor, and he to whom land is let is called the lessee.

There are various legal definitions of a lease. A lease has been defined to be a conveyance of lands or tenements from lessor to lessee for life, for years, or at will, generally in consideration of a rent or other annual recompense to be paid by the lessee to the lessor. The reservation of a rent is not essential in a lease; but payment of rent is now the chief condition on which lands are let.

To constitute a lease, it is necessary that the lands must be let for a less time than the period for which the lessor has an interest in the lands demised. If a man parts with all his interest in the lands or tenements, the conveyance is an assignment, and not a lease. The relation that is created by a lease between the lessor and the lessee is usually expressed by the phrase landlord and tenant. The lessor has a reversion in the lands which are demised, that is, after the expiration of the lease the land reverts to him. The lessor, by virtue of this reversion, seignory, or lord's title, has the power of distraining on the land for the rent which is agreed on, and for the services which may be due by the terms of the lease; and fealty is always due to the lessor. The ordinary lease is that for a term of years, by which lease a rent, generally payable in money, at stated times, is reserved to the lessor. These stated times are usually quarterly periods.

The words used in a lease for the purpose of conveying that interest in the lands which constitutes a term of years are "demise, grant, and to farm let." These words are derived from the law-Latin expressions "demisi, concessi, et ad firmam tradidi." The word "firma," farm, is said to signify originally "provisions," and "to farm let" does not properly signify to let to be farmed, in the modern sense of the term, but to let on the condition of a certain rent being paid in farm, that is, in provisions. If this explanation is correct, a "farmer" is one who had the use of lands on condition of paying a "farm" or rent in provisions, such as corn and beasts. But the word "farm" now signifies the lands which a man hires to cultivate upon the payment of a rent.

The interest which a man acquires in land by a lease for years is a term of years, or an estate for years. The word lease is used in common language also to signify the estate or interest which the lessee acquires by the lease; but the word lease signifies properly the contract or conveyance by which the lessee acquires the interest in the lands.

The words "demise," &c., above mentioned, are the proper words to constitute a lease for years: but any words are sufficient, which clearly show "the intent of the parties that the one shall divest himself of the possession (of the land), and the other come into it for a determinate time." When the written contract was not intended to be a lease, but an agreement for a future lease, it was often difficult to determine whether the contract were not so expressed as to make it a lease.

At common law, it was necessary for the lessor to enter on the lands in order to make the lease complete, and no writing was necessary. But the Statute of Frauds (29 Car. II. c. 3, § 1) enacted, that all leases, estates, interests, of freehold or terms of years, created by livery and seisin only, or by parol, and not put in writing and signed by the parties so making the same or their agents thereunto lawfully authorised by writing, shall have the force and effect of leases or estates at will only, except leases not exceeding the term of three years from the making thereof, upon which the rent reserved to the landlord during such term shall amount to two-thirds at the least of the full and improved value of the thing demised. The Act 8 & 9 Vict. c. 110, enacts that a lease required by law to be in writing made after Oct. 1, 1845, shall be void in law unless made by deed.

The word "lands," which refers to the subject matter of a lease, comprehends what is upon the lands, as houses and other buildings, though houses and buildings are generally mentioned specifically in the lease.

The law of leases comprehends a great number of rules, which may be conveniently reduced to the following general heads:—

1. The things which may be subjects of leases.
2. The persons who may grant leases, and their powers to grant.
3. The form of leases, and the legal construction of the agreements contained in them.

The examination of these subjects belongs to treatises on Law. The article 'Leases and Terms of Years,' in Bacon's 'Abridgment,' is generally referred to as a good compendium of the law. A lease may contain any agreements that are lawful. The object of the present article is to consider what agreements farming-leases should contain or should not contain, in order that the lease may be most beneficial to the landlord and the tenant, and by consequence to the public generally.

The chief subjects of leases are houses and buildings of all kinds, cultivable lands, and mines. Many persons who have not the complete ownership of houses and lands are enabled to grant leases under particular powers; and there are many statutes under which particular

classes of persons are enabled or restrained as to the granting of leases such as bishops, deans and chapters, and others.

The kind of leases of which we shall treat here are farming leases, which are granted by persons who have full power to grant them on such terms as they please. The particular form of such leases, as already intimated, is a matter that belongs to the subject of public economy; and it is almost beyond the province of direct legislation.

At present a great part of the land in England and Wales is held by large proprietors, and the number of land-owners who cultivate their own estates is comparatively small. In many parts of the kingdom the number of small land-owners who cultivate their own farms has certainly been decreasing for some centuries, and they are probably fewer now than in some former periods of our history. In England the great sub-division of land has been prevented by the form of government and the habits and feelings of those who have had the chief political power: and the great increase of wealth that has arisen out of the manufacturing and commercial industry of the country has tended to prevent the subdivision of land and not to increase it. Those who acquire great wealth in England by manufactures and commerce generally lay out a large part of it in the purchase of land; for the ownership of land is that which enables a man to found a family and to perpetuate it, to obtain social respect and consideration, and also political weight in the administration of public affairs. It facilitates his election to the House of Commons, and if he plays his part well, it may introduce him in due time to the House of Lords, and place him among the nobility of England.

Those who cannot acquire land enough to give them political weight, are still anxious to acquire land as a means of social distinction, and as a permanent investment which must continually rise in value. Thus there is a constant competition among the rich for the acquisition of land, which raises its price above its simple commercial value; and a man of moderate means does not find it easy to purchase land in small quantities and on such terms as will enable him to obtain a proper remuneration for the cultivation of it.

The great mass of the cultivators in England are now tenant farmers, who hold their land either by leases for years or by such agreements as amount to a tenancy from year to year only; and there is the like kind of competition among them to obtain land upon lease, that there is among the wealthy to obtain land by purchase. The consequence is that more rent is often paid for land than it is worth: a consequence of the limited amount of land and of the number of competitors for it. This circumstance, however, combined with others, enables the landlord to impose conditions which are unfavourable to the tenant and to agriculture, and finally to himself.

Several things are essential to the good cultivation of land, whether it is held by lease or is the property of the cultivator. These essentials are, a knowledge of the best modes of husbandry, adequate capital, and a market in which the farmer may freely buy and sell all that he wants. Now, in the present state of agriculture in this country, not one of these three conditions exists in the degree which is necessary to ensure good cultivation. The greater part of the land in England, as already observed, is cultivated under leases or a tenancy from year to year; and the covenants in the leases are often such as to be an insuperable obstacle to good agriculture. The condition then of the tenant farmer, as determined by his lease, is that which we have to consider.

Many landholders have several objects in view in letting their lands besides the getting of rent. One of these objects is to maintain their political weight by commanding the votes of their tenantry; and this is mainly effected by not granting them leases of their lands for determinate periods, such as seven, fourteen, or twenty-one years; but by making them very nearly tenants at will, or liable to quit at six months' notice. He who depends for his subsistence on having a piece of land to cultivate, out of which he may be turned on a short notice, will not be an independent voter. Nor can the landlord expect to have a good tenant who will improve his land and a political tool at the same time. The uncertainty of the tenure will prevent a man of skill and capital from investing his money upon so uncertain a return. There may be many cases in which the personal character of the landlord is a sufficient guarantee to the tenant that he will not be disturbed in the possession of the land, even where he has no proper lease, so long as he cultivates it fairly and pays his rent.

But the most intelligent landlords themselves admit that the only proper tenure of the tenant is that of a lease for a determinate period; and it is on this condition alone, as a general rule, that a landlord can get men of capital and skill to cultivate his land. It has been maintained by arguments which are unanswerable, that if lands were let to farmer tenants on leases for a determinate number of years, and on conditions which should not interfere with the land being cultivated in the best mode, there would be a great amount of fresh capital applied to the cultivation of the land, with all the improvements of modern husbandry. It is contrary to experience and to all reason to suppose that a good farmer will apply his skill and capital to improvement of another man's property, unless he has the security that he will be remunerated.

The improvements which would follow from a good system of leasing, would be the abolition of the evils which now exist in conse-

quence of uncertain tenure and of bad leases. It is affirmed by the best authorities that the amount of capital which is now applied to the cultivation of the land in England is very inadequate, that a large part of the farmers have not sufficient capital to improve their lands, nor the necessary skill and enterprise; and it is maintained that these evils are mainly owing to the want of a sufficient security of tenure or the want of a lease, or, where there is a lease, to the absurd restrictions with which many of them abound.

It has been said, and truly enough, that there is no advantage to the landlord in granting a lease to bad cultivators, and that there are many such. Such a lease would not indeed be any advantage to the farmer himself or the community in general; but he who has land to let, and will let it on terms that are mutually profitable to the landlord and the tenant, will be much more likely to get a tenant of competent skill and capital, than he who gives the farmer an uncertain tenure or binds him in the fetters of a bad lease.

The preservation of the game and the enjoyment of the pleasures of the chase, or of the profits derived from the wild animals, is another object which some landlords secure by their lease with as much minuteness and strictness as they do their rent. [GAME LAWS.] Thus, in addition to getting a rent from his land, the landlord often wishes to command the votes of his tenant and secure his game. With reference to these objects and certain other imaginary advantages which he purposes to secure by directing the mode of cultivation, he has a lease drawn up with conditions, restrictions, penalties, and feudal services, which no care on the part of the farmer can prevent him from breaking in some particular, and which no man of capital, skill, and independent feeling would consent to sign.

But these farming leases are often copies of old leases, made in other days, and are unsuited to the present state of agriculture. The things which they require not to be done and those which they require to be done, are often inconsistent with good agriculture, or, in other words, they prevent the land from yielding that amount of produce which it would yield under the best system, not only without thereby being impoverished, but with the certainty of permanent improvement. Ignorance on the side of the landlord of his true interest is one of the reasons why many of these absurd leases still exist.

There can be no principle in the letting of land, if the object be simply to secure the best rent to the landlord and the permanent improvement of the land, which makes it different from the letting of any other piece of property. The good farmer hires land to cultivate, with the hope of deriving profit from the application of his skill and capital. He does not want the advice and direction of another man: he trusts to himself. The first object of the landlord is to get as much rent as his land is worth, and to secure it against deterioration during the tenant's occupation. The terms of the lease, then, should simply be the payment of the rent agreed on, and the observance of such conditions as are found by experience and known to practical agriculturists to be necessary to secure the permanent value of the landlord's land. It is admitted by all reasonable people that the landlord should have ample security by the lease for his land being given up to him at the end of the lease in as good condition as he gave it to the tenant. The tenant wants no directions from the landlord, and no conditions in his favour, beyond the simple condition of being allowed to cultivate the land in the best way that he can for his own profit during a period sufficiently long to secure him a return for his outlay; and he acknowledges that he must submit to all conditions in favour of the landlord which are not inconsistent with his free cultivation, and which shall secure the permanent value of the landlord's property. Perhaps many landlords who now grant hard leases would admit this general principle: but when they came to details, they would insist on many conditions as necessary to secure their permanent interest, which a good farmer would object to as not necessary for that purpose, and also as inconsistent with his profitable cultivation.

The framing of such a lease as we have described in general terms, must be the joint work of intelligent and liberal landlords and of good tenant farmers. It may require some time, some more experience, and suggestions from many quarters before such a lease is got into the best form. But it is an object worth the consideration of all persons interested in the cultivation of the land, and some attempts in this direction have been made already.

The covenants contained in a lease, however few they may be, often occasion difficulty and dispute upon the expiration of the tenancy. The landlord may often claim more than his due, and the tenant may be disposed to do less. These difficulties are not peculiar to farm tenancies; they occur continually in the case of dwelling-houses let for a term of years upon the condition of keeping them in good repair. If such disputes cannot be settled amicably, or by reference to arbitration, the only way is by legal proceedings. It has been suggested that in the case of dwelling-houses in large towns like London, some easy mode of finally settling such disputes might be established. In such cases, the evidence of surveyors is the evidence on which a jury must give their verdict in case of legal proceedings; and it would be quite as satisfactory to all parties, if the evidence that is submitted to a jury, for their judgment, were submitted to a few competent persons to be chosen in some uniform manner, and whose decision should be final.

In 1845 an act was passed (8 & 9 Vict. c. 124) entitled 'An Act to facilitate the granting of certain Leases.' Its object is to substitute abbreviated forms for those previously in use, and it is provided that in taxing any bill for preparing and executing any deed under the act, the taxing officer, in estimating the proper sum to be charged, is to consider 'not the length of such deed, but only the skill and labour employed, and the responsibility incurred in the preparation thereof.' It is enacted in section 4, 'That any deed or part of a deed which shall fail to take effect by virtue of this act shall nevertheless be as valid and effectual, and shall bind the parties thereto, so far as the rules of law and equity will permit, as if this act had not been made.' There are schedules to the act, one of which gives, in column 1, short forms of expression which may be used in place of the ordinary expressions in leases, which are contained in column 2; and it is enacted by section 1, 'That whenever any party to any deed made according to the forms set forth in the first schedule of this act, or to any other deed which shall be expressed to be made in pursuance of this act, shall employ in such deed respectively any of the forms of words contained in column 1 of the second schedule hereto annexed, and distinguished by any number therein, such deed shall be taken to have the same effect and be construed as if such party had inserted in such deed the form of words contained in column 2 of the same schedule, and distinguished by the same number as is annexed to the form of words employed by such party; but it shall not be necessary in any such deed to insert any such number.' This act does not extend to Scotland. The amount of words saved by this act is not sufficient to compensate for the difficulties that may arise from persons using the abbreviated forms in cases where they may not intend them to have the full meaning which this act gives to them. He who wishes to guard himself either as a landlord or tenant by suitable covenants will do better to express his meaning at full length, without availing himself of the abbreviated forms which this act invites him to use.

Leases in general require either an ad valorem stamp, now of very moderate amount, or the common deed stamp, without which the instrument cannot be given in evidence.

LEASE AND RELEASE. Recent legislation has swept away the mode of conveyance by lease and release, which was formerly almost universal. The importance which this legal device formerly had in the system of conveyancing, makes it necessary to give an account of it here. There are various kinds of release, but that intended in the phrase in question, is the relinquishment of some right or benefit to a person who has already some interest in a tenement, and such interest as qualifies him for receiving or availing himself of the right or benefit so relinquished. (Burton's *Law of Real Property*, 45.) Before the passing of the Statute of Uses "it appears that a lease for two or three years was sometimes made, and perfected by entry of the lessee, for the single purpose of his afterward receiving a release of the reversion. Thus arose a sort of compound conveyance, called a lease and release, which, if the grantor were seised in fee simple, had the same effect as a feoffment." (*Ibid.*, 62.)

When it had been determined that the Statute of Uses operated so as to give an estate in land without entry, a lease for a year by bargain and sale was made by the vendor to the purchaser. A use was thus raised to the bargainee, without any enrolment, which in the case of freehold interests was required by the statute of enrolments; and the use thus raised or created for the bargainee was converted, by the Statute of Uses, into a legal estate. Thus the bargainee became immediately capable of accepting a release of the freehold and reversion: and a release was accordingly made to him, dated the day next after the day of the date of the bargain and sale. The release made to a purchaser who has an estate by virtue of the bargain and sale may either be a release at common law as referred to in the passage just quoted, or it may be a release under the Statute of Uses, which is now always meant when we speak of the conveyance called a lease and release.

This conveyance is said to have been first contrived by Serjeant Moore, at the request of Lord Norris, in order that some of his kindred should not know, by any search of public records, what settlement he should make of his estate. The validity of it was formerly doubted. But it was resolved (18 Jac. I.) by the chief-justices Montague and Howard, and chief-baron Tanfield, that upon a deed of bargain and sale for years of land, though the bargainee never entered, if afterwards the bargainor makes a grant of the reversion, reciting the lease, to divers uses, it was a good conveyance of the reversion, (*Lutwich v. Mitton*, Cro. Ja., 604.) And in a subsequent case, where there was a bargain and sale for years, followed by a release, judgment was given, — 'that the lease being within the Statute of Uses, there was no need of an actual entry to make the lessee capable of the release; for, by virtue of the statute, he shall be adjudged to be in actual possession.' (*Barker v. Keate*, 2 Mod., 249.)

In consequence of this interpretation of the law lease and release became the most common assurance for the transfer of freehold estates.

Only a nominal consideration was mentioned in the bargain and sale; and it was held that even a reservation of a pepper-corn rent was a sufficient consideration to raise a use by a bargain and sale on which to found a release.

The recital of a lease for a year, in a deed of release, was good evidence of such lease against a releasor and all claiming under him (but not against strangers), without proving that there was such a deed, and that it was lost or destroyed. Not only estates in possession, but estates in remainder and reversion were conveyed by lease and release. Estates in remainder and reversion expectant on estates for lives might be conveyed by lease and release; as also incorporeal hereditaments, such as advowsons, tithes, rents, &c., for they are expressly named in the Statute of Uses, or comprised under the general word hereditaments. (4 Cru. Dig., 114, 115.)

Lease and release was one of those which were technically called *innocent conveyances*, in contradistinction to those which are termed *tortious*.

A conveyance by lease and release did not divest any estate, or create a discontinuance or forfeiture. Thus Littleton says:—"By force of a release nothing shall pass but the right which he may lawfully and rightfully release, without hurt or damage to other persons, who shall have right therein, after his decease." And in a subsequent section he says:—"If tenant-in-tail lets the land to another for term of years, by force whereof the lessee hath possession, and the tenant-in-tail release all his right in the same land, to hold to the lessee and his heirs for ever, this is no discontinuance: but after the decease of the tenant-in-tail, his issue may enter; for by such release nothing passeth but for time of the life of the tenant-in-tail."

The Act 4 & 5 Vict. c. 21, made the lease for a year unnecessary, and instead thereof it was only required that the act should be referred to in the releasing clause, which thereupon took the same effect as if the lease had been actually made. Subsequently the Act 8 & 9 Vict. c. 110, by enacting that corporeal tenements should be deemed to lie in grant as well as in livery took away all necessity for the legal device of a release; and the simple word grant now supplies the place of the old cumbrous machinery.

LEASE IN SCOTLAND. [TACK.]

LEAST ACTION, PRINCIPLE OF. [ACTION, LEAST.]

LEAST SQUARES, METHOD OF. This is a method, which, since its first introduction, has been shown to be the method of finding the most probable truth, when a number of discordant observations have been made upon a phenomenon. The earliest attempt at anything of the sort was made by Cotes, in a tract entitled 'Estimatio Errorum in mixta mathesi,' in which he very distinctly recommends a process which is identical with that of the method of least squares. It is remarkable that Cotes proposes this theorem not merely as a mode of finding a convenient mean (as was done by Legendre and Gauss), but as giving positively the most probable result. He even introduces the hypothesis of observations having different weights (though not with perfect correctness), and comes as near as possible to the assertion afterwards proved by Laplace. It will be worth while to quote the passage, as follows:—"Mihi vix quidquam ulterius desiderari videatur postquam ostensum fuerit quâ ratione Probabilitas maxima in his rebus haberi possit, ubi diversæ observationes, in eundem finem institutæ paullulum diversas ab invicem conclusiones exhibent. Id autem fiet ad modum sequentis exempli. Sit p locus objecti alicujus ex observatione primâ definitus, q, r, s , ejusdem objecti loca ex observationibus subsequentibus; sint insuper P, Q, R, S , pondera reciproce proportionalia spatiis evagationum, per quæ se diffundere possint Errores ex observationibus singulis prodeuntes, quæque dantur ex datis errorum limitibus; et ad puncta p, q, r, s , intelligantur pondera P, Q, R, S , et inveniat eorum gravitatis centrum z : dico punctum z fore locum objecti maximè probabilem qui pro vero ejus loco tutissimè haberi potest."

Legendre, in his work on comets (1806), first distinctly proposed the application of the method to any case, and Gauss afterwards stated that he had been in the habit of using it since 1795. Finally, Laplace, in his Theory of Probabilities (1814), and we believe in a previous paper published in the 'Memoirs of the Academy of Sciences,' showed that this method was in all cases the one which the principles of that theory pointed out as giving the result, which, from the observations, has the greatest weight of probability in its favour. The details and demonstration of this method may be found in the work of Laplace, cited in the Berlin 'Astronomisches Jahrbuch,' for 1834 and the two following years, and in the treatise on Probabilities in the Encyclopædia Metropolitana.

The most simple case of this method has been in use as long as accurate observations have been made, under the name of taking an average or a mean. If three observations give 93, 94, and 98, then the mean of the three is 95, and if this be assumed as true, it is also assumed that the errors of the observations were 2, 1, and 3. The sum of the squares of these is $4+1+9$, or 14, and this is the least possible sum which can be thus obtained. If for example, we assume anything but 95, say 95.1, the assumed errors are then 2.1, 1.1 and 2.9, the squares of which are 4.41, 1.21, and 8.41, the sum of which is 14.03, more than 14.

But the more extended cases of the method of least squares are those in which the result is not simply observed, but is to be determined by operations upon the results of observation. In all cases the rule is the same: namely, that result has the greatest probability in its favour, the assumption of which makes the sum of the squares of the errors the least possible, provided that all the observations are

equally worthy of confidence. Without entering into further explanation, we shall give the results of one case.

Suppose that A and a are to be determined by observation, the required result being $A \div a$, or the solution of the equation $ax = A$. Suppose also, which is essential to the simple form of the method which we now give, that all the observations, both of A and a , are made under equally favourable circumstances. Say that four observations are made of each; those for a being p, q, r , and s : those for A being P, Q, R , and S . If then all the observations were perfectly correct, each of the equations $px = P, qx = Q, rx = R, sx = S$, would be identical with $ax = A$. Supposing, however, that the observations are discordant, take what value of x we may, the several quantities $px - P, qx - Q, rx - R, sx - S$, will not be (as they should be) each equal to nothing. Whatever their value may be, the whole of each value will be error: and the sum of the squares of the errors, or

$$(px - P)^2 + (qx - Q)^2 + (rx - R)^2 + (sx - S)^2$$

must be made the least possible. The value of x which satisfies this condition is

$$\frac{Pp + Qq + Rr + Ss}{p^2 + q^2 + r^2 + s^2}$$

which is the most probable value.

The method of least squares is now universally used in astronomy, which is perhaps the only science in which so delicate a test is absolutely necessary.

LEATHER MANUFACTURE. Leather (*cuir*, French; *leder*, German; *leer*, Dutch; *læder*, Danish; *läder*, Swedish; *cuoio*, Italian; *cuero*, Spanish; *kusha*, Russian,) is prepared from the skins of animals, or, it would perhaps be more correct to say, consists of that substance after it has been chemically changed by the process of tanning. This change is effected by means of a substance residing in several vegetable matters, to which the name of *tannin* has been given. When this tannin, which is soluble in water, is applied to the hides of animals from which the hair, epidermis, and any fleshy or fatty parts adhering to them are removed, and which hides then consist wholly of *gelatin*, also soluble in water, these two soluble substances so unite chemically as to form the wholly insoluble substance called leather. The object of the tanning process is to produce such a chemical change in skins as may render them unalterable by the external agents which tend to decompose them in their natural state; and in connection with the subsequent operations of dressing, or currying, to bring them into a state of pliability and impermeability to water which may adapt them for the many useful purposes to which leather is applied. Effects in some degree similar are produced by forcing oil or grease into the pores of the skin, or by preparation with alum.

The preparation of skins by tanning or other analogous processes has been practised from the earliest times; and, although it has engaged the attention of several scientific men, and has been the subject of many curious experiments, it has received less modification from recent improvements in chemical science than many other manufacturing processes. Several plans have been suggested with a view to expedite the process, which, on the old system, is a very tedious one, but having been found to deteriorate the quality of the leather, they have been wholly or partially abandoned; and others, which appear to be more successful, are as yet adopted by a few manufacturers only.

Before noticing the tanning and currying processes, it will be desirable to glance at the chief kinds of hides and skins converted into leather.

Among the hides of *oxen*, those supplied by bulls are thicker, stronger, and coarser in the grain than those of cows; while the hides of bullocks are intermediate between those of the bull and the cow. The thickest and most substantial leather now in general use is that made from the hides of the half-wild cattle of South America. Such leather is employed for the soles of boots and shoes; for most parts of harness and saddlery; for leather trunks, buckets, hose for fire-engines, and pump-valves; for the thick belts used in military accoutrements; and for the gloves of cavalry. The thick *buff-leather* formerly used as armour, and which was pistol-proof, and would resist the edge of a sword, was made from the hide of the urus or wild bull of Poland, Hungary, and the middle and southern provinces of Russia; the animal itself being called *buffe*, whence the common name of the leather made from its hide. The skins of *calves*, though thinner than those of cows, are thicker than most other kinds of skin which are converted into leather. They are tawed or alumed for the use of bookbinders, and are tanned and curried for the upper leathers of boots and shoes. It was formerly customary, in the south-west of Ireland, to slaughter cows when in calf; and the celebrated Limerick gloves were made of the exceedingly fine and delicate skins of the unborn calves. *Sheep-skins* vary much in quality. A long fleece always indicates a thin skin; much of the jelly laid up in that organ being, perhaps, the material from which the fleece is elaborated. When simply tanned, sheepskins are employed for inferior bookbinding, for leathering bellows, and for various other purposes for which a cheap leather is required. All the *whit-leather*, as it is termed, which is used for whip-lashes, bags, aprons, &c., is of sheepskin; as are also the cheaper kinds of *wash-leather*, of which brushes, gloves, under-

waistcoats, and other articles of dress are made. Mock or imitation morocco, and most of the other coloured and dyed leathers used for women's and children's shoes, carriage-linings, and the covering of stools, chairs, sofas, writing-tables, &c., are also made of sheepskin. *Lamb-skins* are mostly dressed white or coloured for gloves; and those of *goats* and *kids* supply the best qualities of light leather, the former being the material of the best morocco, of all colours, while kid leather, both white and coloured, affords the finest material for gloves and ladies' shoes. Leather from goat-skins, ornamented and sometimes gilt, was formerly used as a hanging or covering for walls. *Deer* and *antelope* skins, shamoyed or dressed in oil, are used chiefly for riding-breeches. Shamoyed leather breeches were formerly very much used, especially in the army; but being found unhealthy to horsemen exposed to much wet weather, they were superseded by cloth trousers, except in a few special regiments. *Horse-hides*, which, considering their size, are thin, are tanned and curried, and are used by the harness-maker, especially for collars; and occasionally, when pared thin, for the upper leathers of ladies' walking shoes. *Dog-skins* are thick and tough, and make excellent leather; but they have been in a great measure superseded, as a material for dress shoes, by horse-leather and by tanned rat-skins. *Seal-skins* produce a leather similar but inferior to that supplied by dog-skins; and *hog-skins* afford a thin but dense leather, which is used exclusively for covering the seats of saddles. *Porpoise-skins* have lately been made, in Canada, into strong and beautiful leather.

Tanning.—The larger and heavier skins operated upon by the tanner, as those of bulls, buffaloes, oxen, and cows, are technically distinguished as *hides*; while the name *skins* is applied to those of smaller animals, as calves, sheep, and goats. The process necessary to convert hides into the thick hard leather used for the soles of boots and shoes, and for similar purposes, will be first noticed. The hides are brought to the tanner either in a fresh state, when from animals recently slaughtered, or, when imported from other countries, dried or salted, and sometimes both, for the sake of preserving them from decomposition. In the former case the horns are removed, and the hide is scraped to cleanse it from any small portions of flesh or fatty matter which may adhere to the cutis; but in the latter it is necessary to soften the hides, and bring them as nearly as possible to the fresh state, by steeping them in water, and repeated rubbing or beating. After this the hair is removed; sometimes by steeping the hides for several days in a solution of lime and water, which has the effect of loosening the hair and epidermis, or outer skin; and sometimes by suspending them in a close chamber called a *smoke-house*, heated a little above the ordinary temperature of the atmosphere by means of a smouldering fire; in which case the epidermis becomes loosened by incipient putrefaction. In either case, when the hair and epidermis, or cuticle, are sufficiently loosened, they are removed by scraping with a curved knife, the hide being laid upon a convex bench, or 'beam.' The hides are prepared for the actual tanning, or immersion in a solution of bark, by steeping them for a few days in a pit containing

Fig. 1.—Steeping Hides and Skins.

a sour solution of rye or barley flour, or in a very weak menstruum consisting of one part of sulphuric acid mixed with from five hundred to a thousand parts of water. By this process, which is called 'raising,' the pores of the hides are distended and rendered more susceptible of the action of the tan, and the substance of the skin is apparently increased; but, as the process does not add to the gelatin of the skin, a hide which is much thickened by the raising process loses its substance when condensed by the shoemaker's hammer.

Different tanners vary very much in the above processes. Some believe that much of the original gelatin of the hides is never combined with the tannin, but is wasted, owing to defective modes of liming, unhairing, and cleansing. The German tanners often adopt a process called *sweating*, by laying the hides in a pack or pile, and

covering them with spent tan to produce a fermentative heat. On these points much remains yet to be discovered. There are also many variations in practice, in relation to the actual tanning, or conversion of the prepared pelt into leather. Oak bark, crushed or ground to a coarse powder in a bark-mill, is the substance most commonly used to supply the astringent principle. In the old method of tanning, which is not yet entirely abandoned, the hides and powdered bark were laid in alternate layers in the tan-pit, which was then filled with water to the brim. After some months the pit was emptied and re-filled with fresh bark and water; and this process was repeated whenever the strength of the bark was exhausted. In this way the time required for impregnating the hides varied, according to their thickness and other circumstances, from one to four years. The process has been greatly expedited by the improvements introduced in consequence of the experiments of M. Seguin, a French chemist; nevertheless it may be well to observe that skins which are quickly tanned, by the use of strong solutions, produce leather of less durable quality than that which is slowly formed: 100 lbs. of skin, quickly tanned in a strong solution of bark, will produce 137 lbs of leather, while the same weight of skin, slowly tanned in a weak solution, produces only 117½ lbs.; the additional 19½ lbs. in the former case tending to swell the tanner's bill, although it deteriorates the leather, and causes it to contain less of the animal solid.

The variations of practice among different tanners extend to the substance used as an astringent, as well as to the manner of applying it. Ground oak-bark, which was formerly the only material in common use, and is still the most general, produces good leather of a light fawn colour. Valonia produces leather of great solidity and weight, the colour of which is inclined to gray, and which is more impervious to water than that made with oak-bark. Catechu, or terra-japonica, produces leather of a dark reddish fawn colour, which is light, spongy, and very pervious to water. Another substance which has been used of late years is a kind of bean-pod, called divi-divi. These substances may be used either individually or in various combinations. In the methods of preparing tanning solutions there is also considerable variety. Some tanners use cold water for the purpose, and others hot water or steam; others again, instead of pure water, employ ooze, or tanning liquid which has been exhausted by use. A further point of difference is found in the strength of the solutions used, which vary exceedingly. When the impregnation of the hides with tannin is effected by laying them flat in the tan-pits, they are frequently taken out to renew the solution; and the skins which have lain near the top of one pit are laid near the bottom of the next, so as to equalise the amount of hydrostatic pressure. Sometimes the tanning is facilitated by suspending the skins vertically in the liquid, by which means they are penetrated quickly; but the plan requires considerable room, and, unless the skins are frequently moved, it occasions injurious folds in the leather. Another plan, which answers well for small light skins that require but a short time for tanning, is to sew up each skin into the form of a bag, to fill it with tan-liquor, and then immerse it in the pit. The great space required is the principal objection to this plan. In whichever of the above ways the tanning is effected, the hide is subjected to the action of solutions increasing progressively in strength, until it is so perfectly penetrated, that when cut through it presents a uniform brown colour; any appearance of a light streak in the middle of its thickness being an indication of imperfect tanning. When the process is complete, the hides are hung up in a shed, and allowed to dry slowly; and, while they are drying, they are compressed by beating or rubbing, or by passing them between rollers, to give them firmness and density. A yellow deposit is now found upon the surface of the leather, to which the name of bloom or pitching is technically given; and, although this deposit is subsequently removed by the shoemaker in the operation of buffing, and forms a useless addition to the weight and cost of the leather, the prejudice of purchasers requires that it be left on the surface by the tanner.

Although, owing to the many differences in the practice of tanning, no definite time can be stated for the various operations mentioned above, it may be observed that the usual period required for tanning such hides as are used for the soles of men's boots is from six to twelve months; and that from fifteen to eighteen months are required in preparing those of the thickest kinds, which are termed butts or backs. Occasionally hippopotamus hides are tanned, requiring an enormous time for the process; and instances have been known of wild boar hides remaining seven years in tan, to produce leather two inches in thickness.

Before describing the processes for thinner leather, it will be necessary briefly to notice some among the numerous plans for shortening the time involved in the tanning of thick hides. Several schemes have been devised for forcing a tanning solution through the pores of the hide by mechanical pressure. Mr. Spilsbury obtained a patent for this purpose some years ago; but it failed; for it appears that tannate of gelatin was formed on the outer sides of the skins in the form of long masses of slime; while the leather had lost much in weight, was very porous, and unequally tanned, in consequence of the tan-liquor penetrating most readily the thinnest or weakest parts of the hide. A process patented by Mr. Drake consisted in sewing two skins together (after they had received a slight tanning in the ordinary way), so as to form a water-tight bag, which was filled with tan-liquor. The bag thus

formed was compressed between two vertical gridiron-like frames or racks, by which it was prevented from bulging at the sides, and the liquor was confined to a thin vertical stratum. The aqueous portion of the tan-liquor percolated through the hides; and this penetration of the leather was facilitated by heating the room so as to promote evaporation from the exterior surfaces of the bags or skins. In another somewhat similar plan, contrived by Mr. Cox, the hides were sewed up in the form of bags, and supported by a casing of canvas. In the process of Mr. Chaplin, the bags were laid in an inclined position, and turned periodically to equalise the action of the tan. In another plan, which has been tried under several forms, the tanning liquid is applied to both sides of the hides, which are placed in an air-tight vessel, and is forced into their pores by hydrostatic pressure, the air being previously pumped out. The operation may be repeated as often as necessary, with infusions gradually increasing in strength; air being allowed to fill the pores of the hide between each immersion. Mr. Cagwell's plan consists in laying the hides upon a quantity of sawdust, contained in shallow boxes, of which any required number may be arranged in a suitable framework, about twelve inches above one another. The hides are not laid flat, but have their edges a little raised, so that their upper surfaces form shallow troughs capable of holding a layer of the tanning solution, which must be replenished from time to time as it filters through the hide and the sawdust, or other soft porous substance upon which it is laid. The spent liquor runs off from the bottom of the box or trough, which is somewhat inclined for that purpose, into a vessel or channel provided for it. Messrs. Herepath & Cox's process is founded upon the principle of washing a sponge, by alternately allowing it to imbibe water, and then forcibly expressing it. The weak infusion, or ooze, is forced out of the pores of the hide before it is subjected to a stronger, so that the fresh ooze may be able to act more efficiently. This is effected by connecting a number of hides together by strings, so as to form a continuous belt, and passing them between rollers turned by steam or other power, while they are being removed from one solution to another. In order to produce a tolerably uniform belt or continuous sheet of hides, they are either placed alternately head to head and tail to tail; or, if laid across the belt, with the heads and tails towards each side alternately. The lower roller is about thirty inches in diameter, and is covered with horsehair cloth; and the upper roller, which is pressed against the lower one with any determinate degree of force by means of weighted levers, is only about eighteen inches in diameter, and is covered with woollen cloth. By this process a strong hide may be tanned more quickly than by the old method. Much attention has lately been paid to Mr. Preller's process, by which leather is now made at Bermondsey. The hides are first washed; then unhaired; then partially dried; and then covered uniformly with a paste or composition. This paste consists of starchy or glutinous matters, such as barley meal, rice flour, or starch, combined with an oily matter, such as butter, milk, oil, or grease. The paste is smeared on the flesh side of the hide, which is then put into a cylinder or drum, and rotated for some hours with steam occasionally admitted. The hides being taken out and dried, they are pasted and rotated a second and even a third time. At the end of this process they are found to be affected all through by a kind of substitute for tanning. It is said that an ox-hide may be tanned in this way in two days and a half, and a calf-skin in sixteen hours. It seems to be generally admitted that the leather thus made is light, pliable, strong, and durable; it is found useful for certain special purposes, such as driving bands for machinery, picks for looms, and for enamelling. A plan has been brought forward by Mr. Clarkson for so applying a solution of chloride of soda and alumina, and then one of tannin, as to give a surface of leather to the hide, sufficient for many useful purposes.

We might greatly lengthen this list of new processes, but these few will illustrate the whole; especially, as the old operations of the tan-pit have not yet been very extensively departed from in practice. Really good leather is still very slowly made. One inventor has gone so far to employ galvanic agency to drive the tan into the pores of the hide; but the result is unrecorded.

Sumached leather.—We have hitherto alluded chiefly to the preparation of the thick hides used for sole-leather; but the thinner and weaker hides, as well as the skins of calves and other animals, are also prepared for use as upper-leathers; in which case it is necessary to reduce their thickness by shaving or paring them down upon the flesh or inner side, before they are subjected to the action of the tanning infusions. Such hides or skins also require, after leaving the hands of the tanner, to be rubbed, softened, and dressed by the currier, in order to bring them to the necessary degree of flexibility and smoothness. Horse-hides, which are comparatively weak and thin, are sometimes dressed on the grain side, under the name of *cordovan* hides, from the circumstance of such leather having been formerly made at Cordova in Spain. Calf-skins supply the kind of leather most generally preferred for the upper part of boots and shoes.

Of the thin skins prepared for ornamental purposes, many are tanned with a substance called *sumach*, prepared from a plant of the same name. The most important kind is that called *Morocco*, which is made from goat-skins. In the routine of operations, the processes of cleansing the skins from fleshy impurities, and removing the hair, &c., present no material variation from those before described. During these

processes, the lime employed to assist in the depilation enters the pores of the skin so completely, that it would impede the action of the

Fig. 2.—Unbairing Goat-skin.

tanning liquid if allowed to remain. It is therefore removed by immersion in an alkaline solution, which opens the pores in a way resembling the process of raising, described in a previous paragraph. The tanning is then performed by sewing up each skin into the form of a bag, with the grain or hair-side outwards, and nearly filling it with a strong solution of sumach in water. The bag is then fully distended by blowing into it, and the aperture is tied up; after which it is thrown into a large shallow vessel filled with hot water containing a little sumach. The distended bags float in this vessel, and are occasionally moved about with a wooden instrument, until the solution

Fig. 3.—Tanning Goatskins with Sumach.

which they contain has thoroughly penetrated their substance. Owing to the thinness of the skins and the heat to which they are exposed, this operation is performed in a few hours. The process is expedited by taking the bags out of the solution and piling them upon a perforated bench or rack at the side of the tub, so that their own weight may force the confined liquid through the pores. When the tanning is completed, the bags are opened to remove the sediment of the sumach; the skins are washed, rubbed on a board, and dried; after which they are ready for dyeing and finishing with a ridged instrument, which imparts to the surface that peculiar grain by which morocco leather is distinguished. An inferior kind of leather, known as imitation morocco, is prepared in a similar manner from sheep-skins.

Tawed leather.—*Tawing* is the name applied to the process by which the skins of sheep, lambs, and kids are converted into soft leather by the action of alum. Of this kind of leather gloves are usually made. Skins intended for tawing pass through a series of preliminary operations resembling those by which skins are prepared for tanning; but they are then subjected to a solution of alum and salt, to which, for the superior kinds of leather, flour and yolks of eggs are added, instead of a vegetable astringent solution. Sometimes the skins are put into a kind of barrel with the solution, and then the whole is made to rotate rapidly, by which the skins are quickly penetrated; and in other cases the impregnation is effected in an open tub, the skins being worked in the pasty liquid with the hands, or trampled upon by the naked feet of a man, until the emulsion is thoroughly incorporated with them. They subsequently require a good deal of stretching and rubbing over a kind of blunt-edged knife, and some other finishing operations, to give them the requisite smoothness and suppleness. Many of the gloves sold as kid are really made of lamb-skins, of which considerable numbers are imported from the shores of the Mediterranean. These are brought with the wool on; and, as it

would be injured by the action of lime, it is loosened by inducing fermentation or incipient putrefaction in subterranean vaults or cellars; an operation which requires great nicety, since the pelt

Fig. 4.—Dressing Kid Leather.

would be injured by allowing the fermentation to proceed too far. After the wool has been removed, and the skins have been scraped to free them from a slimy substance which exudes from the pores, the pelts are immersed in lime-water for a few days, to remove the grease which yet remains in them. The subsequent operations of removing the lime, tawing, &c., are similar to those required for other skins. In tawing sheep-skins with the wool on, for housings and similar articles, the wool side is carefully folded inwards, to protect it from the tawing liquid or paste, which is then applied to the flesh side only. Alumed leather is made in very large quantities for kid gloves and shoes, real or imitative. The French are skilled in that art. At Annonay, a town about fifty miles from Lyon, the tawing operations are carried on so largely, that 4,000,000 kid-skins are dressed there annually. It has been computed that France and England together consume 6,000,000 eggs yearly, in preparing kid leather. The eggs are kept by the leather dressers in lime-water, to preserve them till wanted for use.

Chamois, or Shamoy leather.—Another kind of leather is that in which oil or grease is forced into the pores of the skin, to take the place of the animal matter. This kind of leather takes its name from a fine soft leather prepared from the skin of the chamois goat; and the process by which it is made is called *shamoying* or *shammying*. Such leather was formerly very much used as an article of clothing, especially by soldiers; and it is still applied to several useful purposes, for which its

Fig. 5.—Shamoy Leather Beating-stocks.

peculiar softness and pliability render it valuable. *Wash-leather* may be cited as a common example of this kind of preparation. The skins of deer, goats, sheep, &c. are dressed in this way; and much shamoyed leather is made from the inferior or least regular portion of split skins, in cases where the grain side has been taken off carefully of a uniform thickness for preparation in a different way. In general, when whole skins are shamoyed, the grain surface is removed by scraping or rubbing with pumice-stone. After the usual preparation

with lime-water, and subsequent washing in a sour infusion of bran or some similar liquor, to remove the lime and open the pores, the skins are made as dry as possible by wringing or pressing them, and are then exposed to the action of fulling-stocks. These consist of heavy wooden hammers, faced with copper, and set in motion by connection with a revolving shaft. The leather, or rather a roll of the skins which are to be made into leather, is placed in a trough, and beaten by the hammers until it is perfectly dry. Cod-oil is then poured upon the skins, and forced into their pores by the action of the hammers or stocks; the form of the trough being such that the skins gradually turn themselves over and over during the operation, to render the beating uniform. When the oil is thoroughly beaten in, the skins are hung up to dry, after which they are returned to the trough to receive a fresh supply of oil and a repetition of the beating. This is repeated eight or nine times, until two or three gallons of oil have been imbibed by one hundred skins; and when they are sufficiently impregnated with it, they are placed in large tubs, or hung up in close heated chambers, in which they undergo a kind of fermentation, by which the pores are distended, and the action of the oil upon the fibres is completed. Finally, the skins are immersed in a weak solution of potash, which removes whatever excess of oil may have remained in the leather, forming with it a saponaceous mixture. They are then hung up in the open air to dry.

Currying and Leather Dressing.—Currying is the general name given to the various operations of dressing leather after the tanning is completed, by which the requisite smoothness, lustre, colour, and suppleness are imparted, to adapt it to the various purposes of the shoemaker, the coach and harness maker, the upholsterer, and others. Every kind of tanned leather not intended for soles, or similar coarse purposes, is generally curried before being delivered to the workman who fashions it. The operation commences by moistening the leather with water, and beating it well upon a strong hurdle with a mallet or mace. After this beating, by which the stiffness is destroyed, the leather is laid over an inclined board, and scraped, cleaned, and pared down on the flesh side, by the careful application of various two-handled knives. It is then thrown again into water, and well scoured by rubbing the grain or hair side with pumice-stone, or with a piece of slaty grit. The leather is next rubbed with the *pommel*, a rectangular piece of hard wood, about twelve inches long and five broad; the currier uses several of these instruments, with grooves of various degrees of fineness, and also, for some purposes, pommels of cork which are not grooved at all. In using the pommel, the object of which is to give grain and pliancy to the skins, the leather is first folded with the grain side inwards and rubbed strongly with it; and subsequently it is rubbed with the pommel upon the grain side, without being doubled or folded. The leather is then scraped with tools applied nearly perpendicular to its surface and worked forcibly with both hands, to reduce such parts as may yet be left too thick to a uniform substance. Finally, the leather is dressed with the *round knife*, a singular instrument shaped somewhat like a saucer, with a cutting edge, and with a hole in the centre for introducing the hands of the workman. It is usually from ten to twelve inches in diameter, with the central hole about four or five inches. This tool is applied with its concave side downwards; and with it, while the leather is stretched over a cylindrical wooden beam, the currier dexterously pares off the coarser fleshy parts of the skin. The currier uses occasionally polishers of smooth wood or glass for rubbing the surface of the leather; and, when the leather is intended for the use of the shoemaker, he applies to it some kind of greasy composition called *dubbing* or *stuffing*.

Leather is occasionally dressed "black on the grain," or having the hair or grain instead of the flesh side coloured. The currying operations in such a case are similar to those above described; but the first blacking is applied to the wet skin immediately after scouring, by rubbing it with a solution of copperas. A brush dipped in an alkaline liquor is then passed over the surface, and an iron slicker is used to make the grain come out as fine as possible. It is then stuffed with oil, and, when dry, *seasoned*, or rubbed over with a brush dipped in copperas-water, on the grain, until it is perfectly black; after which it is slicked with a gritstone, to remove any wrinkles and smooth down the coarse grain. The grain is finally raised by repeatedly rubbing over the surface, in different directions, with the pommel or graining-board.

In connection with the dressing of leather, we may briefly notice *Japanned*, *Russia*, and *Shagreen* leather. Japanned leather of various kinds is used in coach-making, harness-making, and for various other purposes. What is ordinarily termed 'patent leather' is covered with a coat of elastic japan, which gives a surface like polished glass, impermeable to water; and hides prepared in a more perfectly elastic mode of japanning, which will permit folding without cracking the surface, are called 'enamelled leather.' Such leather is usually made black, but may be produced of any required colour. A composition, made of boiled linseed oil, vegetable black, and Russian blue, is rubbed as a thick paste on the surface of the leather by hand; it is dried in a stove heated to 150° or 170° Fahr. This is repeated from three to seven times, according to the excellence of the articles to be produced. Boots and shoes are sometimes made of thin enamelled leather, and they possess the advantage of never requiring blacking, water being sufficient to remove any dirt which impairs their gloss. *Russia* leather

called by the Russians themselves *juten*, is usually dyed red with the aromatic saunders-wood, and is celebrated for being free from mould in damp situations, and not only being proof against insects, but repelling them by its odour, so as to preserve books in the binding of which it is used. The skins are freed from the hair or fleece by steeping them in an ash-lye, then rinsed, fulled, and fermented in a proper steep, after having been washed in hot-water, for a week or more, to raise or open their pores. They are then cleaned, by working them upon the horse, on both sides. They are next soaked for forty-eight hours in a bath composed of water mixed with a paste of rye-flour. The skins, when taken out of the bath, are left in tubs for fifteen days, and then washed. Being thus prepared for the action of the astringent or tanning juices, they are immersed in a boiler containing a hot decoction of willow bark, in which they are handled and pressed for half an hour. This manipulation is repeated twice a day for a week, after which the tanning infusion is renewed, and the process is repeated on the same skins for another week. The skins are then exposed to the air to dry, dyed, and curried with the empyreumatic oil of the bark of the birch-tree. *Shagreen* is a peculiar kind of leather, or rather of prepared skin, formerly much used for the covers of watch-cases, mathematical-instrument cases, &c. The skin, after being soaked in water and scraped to remove the hair, is stretched upon a frame, and the grain-side is strewn with the hard round seeds of the *alabuta*, or goose-foot. A felt being laid over these, they are trodden deeply into the soft yielding skin; after which the frames are so placed in the shade as to allow the skins to dry slowly, when the seeds may be shaken out without violence, leaving the skin in a hard horny state, covered with deep indentations. The surface is then rasped or rubbed down with iron tools, nearly to the bottom of the holes or indentations, the skin during this operation being laid upon a block covered with wool. The skins are next softened, first with water, and then with a warm alkaline ley, and are heaped, while warm and wet, upon each other; and by this softening the depressed parts of the skin rise to their former elevation, forming prominent points wherever depressions had been made by the seeds. The skins are then salted and dyed, after which they are finished with oil or suet.

Great difficulties present themselves in the way of any application of machinery to the dressing of leather, in consequence of the varying hardness, thickness, and texture, not only of different skins, but of different parts of the same skin; yet the great amount of time and manual labour involved in the polishing and graining of morocco and other ornamental leathers has led to some ingenious contrivances for this purpose. Hebert contrived a machine consisting essentially of a stiff circular frame or wheel, eight feet in diameter, revolving horizontally upon a vertical axis, and carrying, on the underside of its periphery, a series of circular polishers or grainers; but it was not brought much into use. Leather-splitting machines, by which even very thin

Fig. 6.—Leather Splitting Machine.

skins may be divided into two thicknesses, each capable of being dressed as a perfect skin, have called forth much ingenuity of contrivance. Before such machines were introduced, the reduction of thickness necessary to bring many of the finer kinds of leather to the requisite tenuity was effected solely, as it still is partially, by paring or shaving the flesh side with a knife worked by hand, an operation occupying much time, and requiring great nicety to prevent cutting through the skin. The part shaved off, also, being necessarily in small pieces, was only available for the making of glue. By the use of a machine, however, the best portion of the leather, that with the grain side, is cut of a much more uniform thickness, and with less risk of injury; the removed portion is taken off in a more useful form; and the whole operation is conducted more rapidly. One such machine is so accurately constructed, that it has been made to split sheep-skins into

three equal parts; one of which, that on the grain-side, might be used as leather, the middle portion converted into parchment, and the slice on the flesh side, being unequal in thickness, and therefore unfit for any better use, being used for glue-making. In this machine, the skin is drawn between two revolving rollers, and is presented, as it emerges from their grasp, to the edge of a long and very sharp knife, which is kept continually moving a little backwards and forwards with great velocity. As a skin of unequal thickness could not be grasped in the proper manner between two perfectly true and rigid rollers, the upper roller, instead of being solid, is composed of a number of circular discs or rings of metal, about half an inch thick, slipped on to an axis; by this contrivance the upper roller is enabled to adapt its surface to that of the skin, which is everywhere pressed with an equal force, due to the weight of the discs of which the upper roller is composed. This machine will split a sheep-skin of the ordinary size in about two minutes, during which time the knife makes from two to three thousand vibratory motions to and fro.

Various kinds of imitative leather have engaged the ingenuity of manufacturers. One, patented many years ago, consists of an elastic coating or varnish of glue-size, boiled linseed-oil, lampblack, white lead, and pipeclay, varying in proportions according to the degree of elasticity required, and spread upon cotton, linen, woollen cloth, or felt. Hancock's substitute for leather consists of a felted fabric of flax, cotton, or other material, covered with several coats of liquid caoutchouc. Gunby's substitute is chiefly intended for the manufacture of patten-ties, but is suitable also for covering coach-tops, and for some other purposes. Crockett's *leather cloth*, and other kinds made in the United States, are very useful products. A clever imitation of Morocco leather is produced by applying a layer of India-rubber or gutta-percha to a surface of cotton-cloth; the surface is corrugated, stained, and varnished; it is elastic and durable, costs only one-third of Morocco leather, and cuts to advantage through being made in great widths. Messrs. Spill & Co., of Stepney, are now manufacturing a remarkable substance under the name of *vegetable leather*. It resembles leather-cloth in being an application of caoutchouc to a woven groundwork or back; but naphtha also takes part in its preparation, and it has other peculiarities. It is producible in pieces 50 yards long by 1½ yards wide, thereby being rendered applicable to many purposes for which hides or skins of real leather would be too small. Its thickness may be varied to any degree by varying the number of cemented layers. Many of the good qualities of leather are presented by it, at one-third the cost. The vegetable leather is used in making carriage and horse aprons, soldiers' belts, buckets, harness, book covers, and other articles.

Various modes of decorating leather are adopted, of which three or four may be briefly noticed. East's *embossed* leather is prepared with the flesh side outwards, instead of the grain side, as in ordinary leather. Sumached sheep-skin is found to be best; it requires many processes, but when completed, the leather presents a very smooth surface, which will receive an embossing by means of heated engraved rollers. Pegg's *corrugated* leather consists of two thin pieces of leather cemented to strips of vulcanised caoutchouc placed between them, then passed between heated grooved or fluted rollers, and finally rendered soft and pliable by soaking in warm water. Wood's *metallic* leather has a metallic ornamental device applied, either by printing with a paste or ink formed by mixing metal powder with starch, bees-wax, and water, or by printing with a glaire or varnish, and sprinkling with metal powder while the surface is wet. In either case the leather is dried by steam-heated cylinders, and the brilliancy of the metal brought out by passing the leather between calendering-rollers. Leake's *relievo* leather is produced by pressing the leather while moist into moulds. Some of the specimens almost equal wood carving or plaster casts in the fineness of detail of the flowers, foliage, fruits, &c., imitated. Relievo medallions have been produced with a relief of more than two inches, and much undercut. The saloon of the Queen's state steamer 'Victoria and Albert' is decorated with this relievo leather. We may here state that the stamped leather, formerly much used for hangings, was made by moistening the leather, laying it on or in a mould, and pressing it into all the minute parts of the devices of the mould by means of small wooden tools; when dry, the leather was coated with silver-leaf, or varnished with lacquer to produce the colour of gold. After this, the proper colouring was laid on by hand, and certain parts of the leather were stamped by a hand-punch to produce various small devices. The French revived this art about twenty years ago, employing hydraulic pressure in stamping. The production of leather ornaments has recently been made a sort of industrial pastime for ladies.

Leather Trade.—The leather manufacture is one of great importance in this kingdom, giving employment in all its various branches to a very great number of persons. The Census of 1851 showed that, taking into the account tanners, curriers, leather dressers, shoemakers, glove-makers, harness-makers, saddlers, and other branches of the leather manufacture, there were 350,000 persons professedly employed in those trades, besides those who were indirectly supported thereby. Our tanners, besides using up nearly all our own oak bark, require annually from abroad 250,000 cwts. of oak bark, 120,000 cwts. of other bark, and 750,000 cwts. of terra japonica, sumach, cutch, valonia, and other substances containing tannic acid. It has been computed that the manufactured articles are worth from three to four times as much as the leather itself, and that the total annual value must be at least

20,000,000%. Most of the leather made in this kingdom, and of the articles formed with it, are used at home. The importations of hides, skins, and articles of leather in 1859 were as follow:—

Hides, untanned, dry	250,296 cwt.
" " wet	611,391 "
" tanned, tawed, or dressed	4,962,192 lbs.
Leather boots and shoes	713,274 pairs
Leather gloves	4,590,261 "

The actual number of hides and skins imported for conversion into leather is not stated in the official returns; but persons in the trade estimated them a few years ago as follows:—

Hides and kips	2,550,000
Calf skins	270,000
Horse hides	230,000
Seal skins	590,000
Goat skins	460,000
Sheep skins	210,000
Lamb skins	1,430,000
Kid skins	50,000
Deer skins	90,000

The exports of leather, except manufactured articles, are very small: they amounted only to 42,136 cwt. in 1859. The leather goods (excluding saddlery) exported were 6,669,210 lbs., with a declared value of 1,359,189*l.*, or about 4*s.* per lb. on an average. The saddlery and harness were estimated only by value, 289,631*l.* The Australian colonies are the great purchasers of all these articles.

LEDITANNIC ACID. [TANNIC ACID.]

LEECHES, MEDICAL USE OF. Of the species described in the article ANNELIDA, in NAT. HIST. DIV., it is intended to treat here only of those of the genus *Sanguisuga* (Savigny), or *Jatrobdeella* (Blainville), as they only can be employed for medical purposes. The same reason induces us to confine our attention to the species *S. officinalis* (Savigny) and *S. medicinalis* (Savigny).

Though the *S. obscura* and *S. interrupta* might be employed to withdraw blood, yet the *S. officinalis* and *S. medicinalis* are chiefly so used. The former is also termed the Hungarian or green leech (*Hirudo provincialis*, of Carena; *S. meridionalis*, of Risco), while the latter is termed the German, or brown, or gray leech, also the true English or speckled leech. The one species abounds in the south of Europe, while the other is a native of the north. The *S. medicinalis* is now rare in England, owing to the draining of so many of the ponds and bogs in which it formerly abounded. The same is nearly the case in France, which used to be supplied chiefly from the district of La Brenne, but now from the frontiers of Russia and Turkey. England derives the immense number required mostly from Sweden, Poland, and Hungary.

The genus *Sanguisuga* is characterised by having the body elongated, the back convex, the belly flat, and the oral and caudal extremities narrowed, before they spread out into discs or suckers. The body consists of from ninety to one hundred or more soft rings, which do not increase in number, but only in size, with the age of the animal, which requires about eight years to come to maturity; and if it escape being devoured by others which prey upon it, it may attain twenty years. The anterior or oral extremity is rather narrower than the caudal: it is provided with ten blackish points or eyes, and a triradiate (not triangular) mouth, furnished with three cartilaginous jaws, each armed with numerous cutting-teeth. The anus is very small, situate on the dorsal surface of the last ring.

The *S. officinalis* has a green body or light blackish-green, the back marked with six longitudinal bands of an iron colour, spotted with black spots at their middle portion and edge. The belly is of a yellowish-green without spots, but broadly bordered with black. The segments of the body are very smooth. It is large, often seven inches long. It lives in pools and rivers. There are three varieties.

S. medicinalis has the body of a deep green, its back marked with six longitudinal bands of an iron colour, pretty clear, spotted with black points, generally triangular. The belly is greenish, spotted, and broadly bordered with black, and the segments of the body rough from granular eminences. It inhabits ponds and small lakes.

Of the anatomy of the leech it is not necessary to say much. The skin consists of two layers, the external or epidermis, and the internal or corium. The first is transparent, resembling a serous membrane; this is thrown off from the body every four or five days. The corium consists of condensed cellular tissue. It displays the divisions into rings, and in it resides the colouring matter of the leech.

The alimentary system consists of the mouth, the stomach, salivary glands, liver, and anus. The mouth has a triradiate figure, formed of three equidistant lines, meeting in a centre, about the middle of the oral disc. Inside are three sublingual jaws or piercers, white, and of a cartilaginous appearance. On the free, curved, sharp margin of each jaw there are about sixty small fine-pointed teeth. The alimentary canal consists of an œsophagus, a long stomach, with cœcal sacs, and

an intestine. The œsophagus is a muscular tube, and commences between the inner angle of the three jaws by a roundish opening: it dilates as it approaches the stomach, but at its termination it contracts into a circular aperture: the whole length does not exceed a quarter of an inch. The stomach occupies two-thirds of the length of the animal, and is formed of eleven compartments or cells. Each of these divisions, that is, from the second to the eleventh, gives off on each side a sac, of which those of the last cell are much the largest. The intestine is about an inch in length; at the upper orifice is a valve, and at its lower a sphincter. These organs can contain nearly half an ounce of blood; so that there is nothing remarkable in the statement that leeches have been known to exist three years in water, without any other nourishment than they could obtain from it; for the blood is received into cells quite distinct, in the first eight of which it remains for months, without undergoing any change either in colour or fluidity: over these cells the animal has a perfect control, merely allowing so much nutriment to pass into the alimentary canal as is necessary to preserve its existence. This accounts for the reluctance of the animal, after being used to abstract blood, to repeat the operation; it not only being gorged at the time, but provided with nutriment sufficient to serve it during almost a sixth portion of its life. In its native abode the true medicinal leech does not seem to take any solid aliment, but subsists on the fluids of fish, frogs, &c.

Leeches are oviparous. The ova remain in the uterus for some time, where they become invested first with a serous membrane, and then with a glutinous fluid, which remains attached to them after their expulsion, and serves as a protecting covering after they are deposited in the clay and holes of the sides of the ponds. The leeches generally deposit the cocoons from May to the end of September. It would seem that these animals do not multiply in great abundance unless they have tasted blood, particularly that of cows. On this account the leech-dealers of Bretagne drive horses and cows into the ponds to such an extent that the cattle of the district are in general wretched-looking, and the leech-gatherers not much better.

About five years are required before the leech attains a state of maturity; while very young they are quite unfit for medical purposes. They are caught in various ways, by the hand, or by a person wading in the shallow waters during the spring of the year, when they adhere to his naked legs; but in summer, as they have retired to deeper waters, a raft is constructed of twigs and rushes, by which a few are entangled. Baits are deposited, generally pieces of decayed animal matter or liver, to which the leeches resort, and are then caught; but this last method is thought to injure the health of the animal. Many sicken and die on the journey, especially during warm weather. They are conveyed either in bags or small barrels with a canvas cover.

Leeches are subject to many diseases, several of which are epidemic, and spread in the troughs with great rapidity. On the first appearance of illness the sick should be immediately separated from the healthy. Care should be at all times taken that different species of leeches be not associated in the same trough, for they prey upon each other. The *Hæmopsis vorax*, and *H. nigra* (*Pseudobdeella*, Blainv.), or common black leech, devour greedily the *S. medicinalis* or *S. vulgaris*, though they cannot penetrate the skin of vertebrated animals. The horse-leech, *Hæmopsis sanguisodea*, Sav. (the *Hirudo sanguisuga*, Linn.; *Hypobdeella*, Blainv.), is not certainly without the power of penetrating the human skin, though the black leech, often confounded with it, has no such power, from want of teeth.

A leech may be known to be in good health if it be active in the water and plump when taken out. In Prussia leeches are divided into three classes, according to their weight: the first not exceeding 30 grains; the second weighing between 30 and 60 grains; the third from 60 to 90. Leeches above 90 grains are not to be used, unless specially ordered. In each prescription the physician is required to state what description of leech he intends should be used. In the case of children such regulations are highly proper, as an excess of blood abstracted may easily produce serious and often fatal consequences. Leeches vary in the quantity they can abstract, from one drachm to half an ounce: from one to two drachms is the average. The quantity is often doubled by the expedients resorted to after the leech has been removed, either dry or wet clothes being applied, or in many cases cupping-glasses, but cataplasms of linseed-meal are most beneficial where they can be applied.

One gray or German leech is deemed equivalent to two green or Hungarian leeches. The cases requiring or justifying the application of leeches are stated under the respective diseases, and need not be repeated here. It is of more importance to indicate the proper mode of applying them. The leech, though not so accurate an index of the weather as is commonly believed, is yet sensible of atmospheric changes, and in some (probably peculiarly electric) conditions of the atmosphere cannot be induced to bite. In such cases time ought not to be wasted, nor the patient exposed injuriously or kept in a fatiguing position, but some other mode of blood-letting should be had recourse to. Moreover, if the leech be sickly, it can rarely be made to bite. Certain states of the patient also hinder or indispose them to bite. Where the skin is very thick they cannot puncture it; or if the person has been using sulphur, the exhalation of the sulphuretted hydrogen is disagreeable to them; even the fumes of tobacco, vinegar, &c., will prevent

them biting; also if grease, salt, or vinegar be on the spot to which they are applied, they refuse to attach themselves to it. The existence of hairs on the spot seem to hinder them from biting, and also from forming a vacuum to suck up the fluid, on which account they should be carefully shaved off. The leeches should be taken out of the water, and allowed to creep for some time over a dry warm cloth; in the meanwhile, the part where it is intended to apply them should be washed with *plain* (not perfumed) soap and water, then with water alone, afterwards with milk or porter. It is difficult to make them fix themselves on the particular spot wished; but a leech-glass will generally effect this, and is preferable to holding the leech in the hand. When they still refuse to bite, slightly puncturing the part with any sharp instrument, so as to cause a little blood to ooze out, is a useful expedient; or if we pluck a feather from the wing of any bird, and, cutting off the end, allow the liquid contained in it to be dropped on the spot, the leech will bite readily.

When the leech has dropped off, it should be seized by the tail or caudal end, and striped between the finger and thumb, so as to cause it to disgorge most of the blood. It is proper to allow it to retain a third of the blood. This is preferable to applying salt or vinegar to the mouth. It should then be placed in many successive fresh waters, and it may perhaps survive, and after many months be again fit for use. In winter, it should be put at first into tepid or luke-warm water; for though *cold-blooded* itself, its body has been filled with blood of a temperature of nearly, or perhaps above, 100° Fahr.

When no expedient is had recourse to, in order to maintain the flow of blood, it generally stops spontaneously; but in some cases it continues much longer than is proper. Where the blood is either deficient in coagulating power, as happens in many weak persons, or when it is in a very alkaline state, and the albumen in too dilute a condition, or owing to the very vascular state of the skin of children, the hæmorrhage is often troublesome, and in the case of children, who do not bear well the loss of a large quantity of blood, sometimes fatal. The object of any remedial means is to form a coagulum, or plug, at the mouth of the bleeding vessels. A weak solution of creasote applied to the part will generally effect this, or felt scraped from a hat, or gum in powder, or flour, or the dust of the puff-ball (*lycoperdon* or *bovista*), or the application of a compress and bandage, tying a ligature, or touching the wounds with lunar caustic. The patient should at the same time drink a saturated solution of alum, or take dilute sulphuric acid out of very cold water.

The increasing scarcity of leeches renders their preservation and propagation objects of primary importance. The death of a vast number of leeches is occasioned by errors in the method of keeping them. Though aquatic animals, it is not enough that they be supplied with water. They breathe by their entire surface, and are accustomed to change their skin every four or five days. Their body is covered, like that of all animals and plants which inhabit the water, by a slimy or mucilaginous fluid, which not only enables them to glide through the water, but keeps an aerial stratum in close contact with their respiring surface. When present in a limited degree, this mucous secretion is highly serviceable to them; in excess, it is destructive. It is impossible for them to diminish it when it has accumulated, or to denude themselves entirely of their old skin, in water only. They must have some resisting body to creep over or through in order to accomplish this object. Some leech-dealers keep clay at the bottom of the troughs, and though this is useful as a material in which the leeches can burrow in warm weather (by which they are always more injured than by cold, if not intense; and it is their habit to retreat to the deepest waters of their native rivers or ponds in summer), it is inadequate to the end. The best method seems the following recommended by Fee:—

Into a marble or stone trough a layer of seven inches of a mixture of moss, turf, and charcoal of wood is to be put, and some small pebbles placed above it; at one extremity of the trough, and midway between the bottom and the top, place a thin plate of marble pierced with numerous small holes, upon which there should rest a stratum of moss or portions of the *equisetum palustre*, or horse-tail, firmly compressed by a stratum of pebbles. The trough to be replenished with water only so high that the moss and pebbles should be but slightly moistened. A cloth is to be kept over the mouth of the trough. This is imitating as near as possible their natural condition, and the charcoal not only aids in keeping the water sweet, but appears to prevent the leeches being attacked by parasitic animals, to which they are very liable. The water should be changed about once a week, and more frequently in warm weather.

Leeches have not been observed to propagate when kept in small bodies of water, but in large reservoirs, having a body of turf and rushes, and the sides well furnished with clay, in which to deposit the cocoons, Dr. Noble of Versailles has succeeded in procuring young ones. It has also been ascertained in France that leeches which have been used, if restored to their natural haunts, propagate abundantly, and also become capable of being again applied after eight or twelve months' stay in these congenial quarters.

The great extent to which the trade in leeches is carried on renders attention to this subject of paramount importance. Four only of the principal dealers in London used to import 7,200,000 annually, and in

Paris 3,000,000 are used. But in England the consumption of leeches is now (1860) very greatly diminished.

Leeches have sometimes been swallowed; and in Syria and other places a small leech is sometimes drank with the waters of the pools, and by adhering to the throat causes great suffering. Salt or vinegar is the best means of dislodging them. Besides these Syrian leeches, there is in Ceylon, the lower range of the Himalayan Hills, Batavia, and other islands a land-leech (*Hæmadipsa Ceylonica*, Bosc.) which is of a formidable nature, not from its size, "for they are only about an inch in length, and as fine as a common knitting-needle; but capable of distension till they equal a quill in thickness, and attain a length of nearly two inches. Their structure is so flexible that they can insinuate themselves through the meshes of the finest stocking, not only seizing on the feet and ankles, but ascending to the back and throat, and fastening on the tenderest parts of the body. The coffee planters, who live among these pests, are obliged, in order to exclude them, to envelope their legs in 'leech-gaiters' made of closely woven cloth. The natives smear their bodies with oil, tobacco ashes, or lemon-juice; the latter not only serving to stop the flow of blood, but to expedite the healing of the wounds. These creatures are gregarious, and make their attacks in concert, with such well directed tactics, that it is difficult to elude them." 'Ceylon,' by Sir J. E. Tennent, vol. i. p. 301 of 2nd edition. In the same island, a cattle-leech (*Hæmopsis paludum*) is most formidable to cattle which go to drink in the ponds frequented by them. They are very insidious, and their bite at first gives little pain, but the consequences are often fatal. (Ibid p. 306.) These are probably the same as are mentioned by Pliny ('Hist. Natur.' viii. 10.) as distressing the elephants.

(Johnson *On the Medicinal Leech*; Brandt and Ratzeburg, *Getreue Darstellung der Thiere*; and Mr. Pereira's *Mat. Med.*)

LEET is the precinct or district within the cognisance or subject to the jurisdiction of a court-leet. Sometimes the term is used to denote the court itself, the full style of which is "the court-leet and view of frank-pledge." The court-leet is also called a law-day, as being the ordinary tribunal.

I.—Origin of the Court-leet.

One of the least improbable derivations of the word "leet" seems to be that which deduces lath and leet from the Anglo-Saxon "lathian," or "gelathian," to assemble; both lath and leet indicating, under different modifications, a district within which the free male residents (residents) or indwellers assembled at stated times, as well for preparation for military defence as for purposes of police and criminal jurisdiction. Of the first of these objects scarcely any trace exists in the modern leet. The title of the court as a "view of frank-pledge," points to its former importance under the extensive system of police introduced or perfected by King Alfred, which required that all freemen above twelve years of age should be received into a decennary, or tithing, called in Yorkshire and other parts of the north, "ten-men-tale" (number, tale, or tally of ten men), and forming a society of not less than ten friborgs or freeborrows (freemen), each of whom was to be *borhoe*—that is, pledge or security for the good conduct of the others. So the German "bürge," pledge or surety (fidejussor), appears to be derived from the verb "borgen," to give or take on credit. In this sense, in the 'Franklin's Tale,' Chaucer has, "Have here my faith to borwe;" and in the 'Squire's Tale,' "St. John to borwe."

In the ballad of 'The Rising in the North,' preserved in Percy's 'Reliques of Ancient Poetry,' Lady Northumberland, proposing to her husband to place herself in the hands of Queen Elizabeth, as a surety or hostage for his submission, says, "Thy faithful borrow I will be."

When a party was accused of a crime, his tithing was to produce him within 31 days, or pay the legal mulct for the offence, unless they proved on oath that no others of the tithing were implicated in the crime, and engaged to produce him as soon as he could be found. For great crimes the offender was expelled from the tithing, upon which he became an outlaw.

The duty of inspecting a decennary or tithing was called a view of frank-pledge, the freeborrows having received from their Norman conquerors the designation well known in Normandy of frank-pledges. The principal or eldest of these freeborrows, and as such the person first sworn, who was denominated the tithing-man, sometimes the headborough or chief pledge, sometimes the borsholder or borsalder (borhes-alder, or senior or ruler of the pledges), and sometimes the reeve, was in an especial manner responsible for the good conduct of each of his co-pledges, and appears to have had an authority analogous to that still exercised by the constable, an officer elected by the residents for the preservation of the peace within the district constituting the leet, tithing, or constablewick. This officer is in many places called the headborough, which designation, as well as those of borsholder and tithing-man, is frequently used by the legislature as synonymous with that of constable. It is probable that all the frank-pledges were numbered according to rank or seniority, as in places where more than two constables are required, the third officer is called the thirdborough. Blackstone, misled by the sound, supposes headborough to be the chief person or head of a town or borough. This derivation will remind the readers of 'Hudibras' of the "wooden bastile" (stocks), which

"None are able to break thorough,
Until they're freed by head of borough."

The Holkham manuscript of the Anglo-Saxon customary law says: "A tithing (there called *decimatio*) contains, according to local usage, ten, seventy, or eighty men, who are all bound (*debent*) to be pledges (*fidejussores*) for each other. So that if any of them be accused (*calumpniam patitur*), the rest must produce him in court; and if he deny the offence, he is to have lawful purgation by the tithing (that is, by their swearing to their belief of his innocence). A tithing is in some places called a *ward*, as forming one society, subject to observation or inspection within a town or hundred. In some places it is called "borch;" that is, pledges for the reasons above stated. In others it is called tithing (in the original, *decimatio*), because it ought to contain ten persons at the least."

The assizes of Clarendon directed "that all the customs of frank-pledge should be observed; that a person receiving men into his house or land, or within his jurisdiction (*soke*), who were not in frank-pledge, should be answerable for their appearance, and that no franchise or liberty [*LIBERTY*] should exclude the sheriff from entering for the purpose of seeing that views of frank-pledge were duly held."

Leets are either public or private. The public leet is an assembly held in each of the larger divisions of a county, called a hundred, at which all freemen who are residents within the hundred are bound to attend in person or by their representatives. These representatives were the reeves or chiefs of their respective tithings, whether designated by that or by any of the other appellations, each of whom was accompanied by four good and lawful men of, and elected by, the tithing which deputed them. This public court-leet was held formerly by the royal governor of the county, the ealdorman of the Saxons, the earl of the Danes, the comes or count of the Normans. This great functionary was accompanied by the shire-reeve, an officer elected by the county to collect the king's rents and the other branches of the royal revenue, who, in the absence of the ealdorman, presided in the court, and governed the county as his deputy, whence he is called by the Normans a vice-comes or vicount, though in English he retained the name of shire-reeve or sheriff, the designation connected with his original and more humble duties. This public court, which was originally called the folk-mote, being held successively in each hundred in the course of a circuit performed by the sheriff, acquired the name of the sheriff's *tourn*, by which name, though itself a court-leet, it is now distinguished from inferior private leets. The latter courts appear to have been created at a very early period by grants from the crown obtained by the owners of extensive domains (which afterwards became manors) [*MANOR*], and most frequently by religious houses, for the purpose of relieving their tenants and those who resided upon their lands from the obligation of attending the tourn or leet of the hundred, by providing a domestic tribunal, before which the residents might take the oath of allegiance and the frank-pledges might be inspected, without the trouble of attending the tourn, and to which as an apparently necessary consequence, the criminal jurisdiction of the precinct or district was immediately transferred. In these private leets the grantee, called the lord of the leet, performed the duties which, in the public leet or tourn, after the ealdorman or earl had permanently absented himself, fell upon the sheriff. Their duties he might perform either personally or by his steward; and as a compensation for this, and his trouble in obtaining the franchise, it appears to have been the practice for the great land-owner who by his money and his influence had procured the grant of a private leet to claim from residents a certain small annual payment by the name of *certum letæ*. The tenants within the precincts of a private leet, whether in boroughs, towns, or manors, formed a body politic wholly independent of the tourn or leet of the hundred; whilst such upland, or unprivileged, towns as had not been formed into or included within any private leet, still appeared, each by its tithing-man or reeve and four men of the tithing, and formed part of the body politic of the hundred. Each of these communities appears to have exercised most of those rights which it has latterly been supposed could not exist without incorporation. In many cities and boroughs the ancient authority of the court-leet was in later times superseded by charter of incorporation, in some of which the important right of popular election of magistrates was preserved entire; whilst in the great majority of cases the right, though continued in name, was fettered, if not rendered altogether nugatory, by restrictions of various characters and degrees, which are still to be seen in boroughs not regulated by the Municipal Corporation Act. In other respects the course prescribed by these charters was adapted to the changes which had taken place in the habits of the people since the institution of the court-leet. Many of the functions of the magistrates in the new incorporations were borrowed from the then comparatively recent institution of justices of the peace.

II.—Constitution of the Court-leet.

This court is a court of record, having jurisdiction of such crimes as subject the offenders to punishment at common law. The exclusive exercise of criminal jurisdiction being inherent in the kingly office, all criminal matters are denominated pleas of the crown, and the courts in which such pleas are held are the king's courts, although granted to a subject; for such grant operates merely as an authority to the grantee to preside judicially by himself or his steward, and to take the profits of the court to his own use. The authority so exercised under the king's grant is called a lordship, and the grantee is said to be the

lord of the leet. It may be claimed either by a modern grant or by prescription, that is, long established user, from which an ancient grant is presumed. The grantee, whether claiming under a grant still extant or by prescription, is commonly the lord of a manor, and the leet is usually coextensive either with the actual limits of the manor, or with its boundary at some former period. There may however be several leets in one manor, and a leet may be appendant to a town, or to a single house. It is not necessary that the lord of the leet should have a manor, or indeed that he should have any interest in the land or houses over which the leet jurisdiction extends. As the leet was originally granted for the more convenient administration of justice, the lord may be required by writ of mandamus to hold the court. Upon non-user of a leet, the grant is liable to be seized into the hands of the crown, either absolutely as for a forfeiture, or *quousque*, that is until the defect be amended; the same consequence ensues upon neglect to appoint an able steward and other necessary officers, or to provide instruments of punishment.

Private leets are commonly held, as public leets *must* be, twice in the year, within a month after Easter, and within a month after Michaelmas, and even the former cannot, unless warranted by ancient usage, be held at any other time except by adjournment. The court appears to have been formerly held in the open air. It should be held at its accustomed place, though, if sufficient notice be given, it may be held anywhere within the precinct. All persons above the age of twelve years and under sixty (except peers and clergymen, who are exempted by statute, and women and aliens), resident within the precinct for a year and a day, whether masters or servants, owe suit to (that is, personal attendance at) this court, and here they ought to take the oath of allegiance. The suit to the court-leet is said to be real (that is, regal or due to the king), because every one bound to do suit to such court as a resident, is also bound to take the oath of allegiance unless he has taken it before. But where a non-resident is bound by tenure to join with the residents in making presentments at the court-leet, the duty is not suit-real, for he shall not be sworn to his allegiance, &c., at this leet. It is merely suit-service, that is, a suit forming one of the services due from the tenant to his lord in respect of the tenure. A man who has a house and family in two leets, so as in law to be conversant or commorant in both, must do his suit to the leet where his person is commorant, namely, where his bed lies, but if he occasionally reside in both, he is bound to do suit to each.

III.—Jurisdiction of the Court-leet.

The Anglo-Saxon Hundred Court appears to have had jurisdiction in all causes, civil, criminal, and ecclesiastical; and also to have had the cognisance and oversight of all the communities of frank-pledges within the hundred, the members of these communities being bound for that purpose to attend at the Hundred Court by themselves or their elected representatives. The jurisdiction of the Hundred Court in ecclesiastical matters was taken away by an ordinance of William the Conqueror, forbidding the attendance of the bishop.

It was the province of the court-leet, as well the public leet of the hundred, as the private leet, to repress all offences against the public peace, and to enforce the removal of all nuisances affecting the public convenience.

The leet jury possess a legislative authority in establishing by-laws. By-laws made in a court-leet and embodied in the presentments of the jury in respect of matters properly cognisable in the leet, are binding upon residents, but not upon strangers. [*BY-LAW*.] A by-law imposing a penalty of 5*l.* per month for taking or placing an inmate without giving security to the overseers against any charge upon the parish was said by Lord Hale to be usual and valid. The leet jury elect their own chief magistrates, the reeve or constable, &c., of the private leet, and, as it would seem, the high constable (sometimes called the alderman) of the hundred.

Before the Norman conquest, and probably for some time after, this court of the leet was, if not the sole, at least the ordinary tribunal for the administration of criminal justice in the kingdom. Until the reign of Henry I., when, with respect to certain heinous offences, the punishment of death was substituted for pecuniary compositions, no crime appears to have been punished by death except that called in the laws of that prince "*Openthifte*," a theft where the offender was taken with the *mainour*, that is, with the thing stolen upon him. [*ROBBERY*.] Of this crime, as requiring no trial or presentment, the leet had no cognisance. Other offences, of however serious a nature, subjected the party to a mulct, or pecuniary fine, the amount of which was in many cases determinate and fixed.

Offences to be merely inquired of in leets are arson, burglary, escape, larceny, manslaughter, murder, rape, rescue, sacrilege, and treason, and every offence which was felony at common law. These offences being presented by the leet jury as indictors, and the indictment being certified to the justices of gaol delivery, the indictments may be arraigned; but they cannot be arraigned upon the mere production of the court-roll containing the presentments. Formerly all offences inquirable in leets were also punishable there by amercement; but the power of adjudicating finally upon crimes in courts leet, whether public or private, is now limited to such minor offences as are still left under the old system of pecuniary compensation. No matters are

cognisable in the leet unless they have arisen or have had continuance since the last preceding court.

An amercement is a pecuniary punishment which follows of course upon every presentment of a default or of any offence committed out of court by private persons. Amercements are to be mitigated in open court by affeerers (afferratores, from afferrare or afforare, *afferer*, to tax, or fix a price, hence the term *afforage*, used in the old French law to denote the judicial fixing of a price upon property to be sold). The affeerers by their oaths affirm the reasonableness of the sum at which they have assessed the amercement. This course is sanctioned and confirmed by Magna Charta, which directs that amercements shall be assessed by the peers of the offender, that is, the *pares curiæ*, or suitors of the same court. [JURY.] The amercements, being affeered, are estreated (extracted) from the court-roll by the steward, and levied by the bailiff under a special warrant from the lord or steward for that purpose, by distress and sale of the goods of the party, which may be taken at any place within the precinct, even in the street: or the lord may maintain an action of debt for such amercement. For a nuisance, the jury may amerce the offender, and at the same time order that he be distrained to amend it.

The steward of a leet is a judge of record, and may take recognisances of the peace; and he may impose a fine for a contempt or other offence committed in court, as where a party obstructs the jury in the execution of their duties, or by public officers in the discharge of their duties out of court. The amount of the fine is at once fixed by the steward, and therefore, though sometimes loosely called an amercement, it is not to be affeered. When a suitor present in court refuses to be sworn, it is a contempt for which a reasonable fine may be imposed; so if the jury, or any of them, refuse to make a presentment, or depart without making it, or make it before all are agreed. In all matters within the cognisance of a court-leet the lord or steward has the same power as the judges in the superior courts. He has indeed no power to award imprisonment as a punishment for offences presented in the leet, such offences being the subject of amercement only: but he may imprison persons indicted or accused of felony before him, and persons guilty of a contempt in face of the court.

Of common right the constable is to be chosen by the jury in the leet; and if the party chosen be present, he ought to take the oath in the leet; if absent, before justices of the peace. If he refuse to accept the office, or to be sworn, the steward may fine him. If the party chosen be absent and refuses, the jury may present his refusal at the next court, and then he is amerced. But a person chosen constable in his absence ought to have notice of his election. A mandamus lies to the steward of a leet to swear in a constable chosen by the jury. By 13 & 14 Car. II., cap. 12, when a constable dies or goes out of the parish, any two justices may make and swear a new one until the lord shall hold a court-leet; and if any officer continue above a year in his office, the justices in their quarter-sessions may discharge him, and put another in his place until the lord shall hold a court. But the justices at sessions cannot discharge a constable appointed at the leet; and though they can appoint constables until the lord shall hold a court, they cannot appoint for a year, or till others be chosen. A person chosen constable who is deficient in honesty, knowledge, or ability, may be discharged by the leet or by the Court of King's Bench as unfit. The steward may set a reasonable fine on a constable or tithing-man refusing to make presentments.

Though the leet has long ceased to be the principal and ordinary court of criminal jurisdiction, its power and authority have been enlarged by several statutes, which give it cognisances over offences newly created, and it does not appear to have been at any time directly abridged by legislative interference. The business of the court has chiefly been affected by the creation of concurrent jurisdictions, particularly that of justices of the peace [JUSTICES OF THE PEACE], who have cognisance of the same matters, as well as of many others over which the court-leet has no jurisdiction. Justices of the peace are always accessible, whereas the court-leet is open only at distant intervals, and for a short period, unless it be continued by adjournment, which can only take place for the despatch of existing business. Another cause of the declension of these tribunals is that except in a very few cases the jurisdiction of the leet is confined to offences punishable at common law. In statutes providing for the repression of new offences, the leet is commonly passed over in favour of justices of the peace. Blackstone reckons "the almost entire disuse and contempt of the court-leet and sheriff's tourn, the king's ancient courts of common law formerly much revered and respected, among the mischievous effects of the change in the administration of justice by summary proceedings before justices of the peace." It was not, however, left to the learned commentator to make this discovery. In the course of the very reign which witnessed the introduction of the modern system of justices of the peace, we find the Commons remonstrating against the violation of the Saxon principle of self-government and domestic administration of justice, resulting from the encroachments made upon the ancient jurisdiction of the leet by giving to the new tribunal of the justices of the peace a concurrent jurisdiction in matters usually brought before the court leet, and an exclusive jurisdiction in other important matters. In the last year of Edward III. (1377), the

Commons, by their petition in parliament, prayed the king that no justice of the peace should inquire of anything cognisable in the courts of lords who had view of frank-pledge, or of anything cognisable in any city or borough within their district, and should attend only to the keeping of the peace and the enforcing of the statute of labourers. To this petition the king returned the following unsatisfactory answer:—"The statutes heretofore made cannot be kept if the petition be granted." At this time, and until the passing of 27 Hen. VIII., c. 24, offences in leets were alleged to be against the lord's peace, not the king's.

IV. Manner of holding the Court-leet.

The common notice of holding the court is said to be three or four days; but it is now usual to give fifteen days' notice. An amercement at a court of which sufficient notice has not been given is void. But even where there is a clear prescriptive usage to give a certain number of days' notice, the resiants cannot disturb the holding of the court on the ground that such notice has not been given.

The functions of the steward of a court-leet are mostly, if not wholly, judicial. Ministerial acts are to be performed by an inferior officer called the *bedel* or bailiff, who of common right is appointed by the lord or steward, though by custom he may be chosen by the jury, and sworn with the other officers chosen at the leet; and where, in a leet appendant to a borough, the bailiff so chosen has a discretionary power in impannelling the jury, this important function is a sufficient ground for issuing a *quo warranto* to inquire into the title of the party exercising it. The steward, at the customary or at a reasonable time before the holding of the court, issues a precept under his seal, addressed to the bailiff of the leet, commanding him to warn the resiants to appear at the time and place appointed for holding the court, and to summon a jury. The notice may be given in the church or market, according to the usage of the particular place; but it is said that if it be not an ancient leet, personal notice is necessary. According to the course most usually pursued, the steward opens the court by directing the court to be proclaimed; and this being the king's court, it is necessary that three proclamations should be made. This is done by the bailiffs crying 'Oyes' (hear) three times, and then saying once 'All manner of persons who are resiant or deciners and do owe suit royal to this leet, come in and do your suit and answer to your names upon pain and peril which shall ensue.' The bailiff then delivers to the steward a list of persons summoned as jurymen, together with the suit or resiant roll. The suit-roll is then called over, and those resiants who are absent are marked to be amerced. The bailiff then makes three other proclamations, by crying 'Oyes' three times, and then saying 'If any man will be essoigned, come in, and you shall be heard.' The steward having called for the essoigns, enters them. The essoigns should regularly be adjourned to the next court for examination in the court roll or book.

Suit-real must be done in person; it cannot be done by attorney; nor can it, as it would seem, be released by the lord. But the suitor may be essoigned or excused *pro hac vice*, which is done generally upon the payment of an essoign penny.

The constables are next examined as to their compliance with the orders received by them at the previous court. After this the leet jury is formed. This jury is chosen from the body of the suitors, and consists of not less than twelve, nor more than twenty-three. In some leets the jury continues in office for a whole year; in others the jurors are elected and discharged in the course of the day. A custom for the steward to nominate to the bailiff the persons to be summoned on the jury is valid. If a sufficient number of resiants to form a jury cannot be found, the steward has power to compel a stranger to serve, even though he be merely travelling through the district, and is actually riding on his journey at the time his services are required; but a woman, though a resiant, cannot be sworn.

After the jury is chosen a foreman is named, who is sworn as follows:—"You shall well and truly inquire, and true presentment make, of all such articles, matters, and things as shall be given you in charge; the king's counsel, your companions', and your own, you shall keep secret and undisclosed. You shall present no man for envy, hatred, or malice; nor spare any man for fear, favour, or affection, or any hope of reward; but according to the best of your knowledge, and the information you shall receive, you shall present the truth and nothing but the truth." As soon as the foreman is sworn, three or four of the jury, taking the book together, are sworn to observe and keep, on their parts, the same oath which the foreman has taken on his part. The jury then receive a charge from the steward, pointing out the nature of their duties, and of the matters which ought to be presented. The jury make their presentments to the steward, who, in cases of treason or felony, must return the presentments (in these cases called indictments) to the justices of gaol delivery if the offenders be in custody; if they be at large, the indictments must be removed into the King's Bench by *certiorari*, in order that process may issue thereon. In all other cases the steward of the leet has power, upon the complaint of any party grieved by the presentment, or, on the other hand, upon any suspicion entertained as to the concealment of any offence, by non-presentment, to cause an immediate inquiry into the truth of the matter by another jury, though in the former case the more usual course now is by *certiorari* or traverse.

A court-leet may be adjourned if the business of the particular court require it. This should be done by three proclamations. A court held on the 28th April, and adjourned, after the jury had been sworn, till the 15th December, which day was given them to make their presentments, has been held not to be necessarily unreasonable.

It is not necessary that notice should be given of an order made by the leet for abating a nuisance; the party being within the jurisdiction, must take notice of it at his peril. For the same reason he is also bound to take notice of a by-law.

V. Profits of Court.

The ordinary profits of a court-leet are the fines, amercements, and essoign pence, and belong, in the case of a public leet or tourn, to the crown; in the case of a private leet, to the grantee or lord of the leet. It would rather seem, however, that the lord is bound to account at the Exchequer for these profits, though he may discharge himself by showing his title. In a private leet also, the lord, as above mentioned, is entitled to a further payment, in the nature of a poll-tax, capitagium, or chevage, by the name of certum letæ, sometimes called cert-silver, certainty-money, cert-money, and head-silver. When this payment is to be made on the day of the leet the defaulters may be presented and amerced. For such amercement the lord may distrain; but he cannot distrain for the cert-money itself, without a prescription to warrant such distress. In the absence of both amercement and prescription, the lord's remedy is by action of debt.

LEGACY (Legatum), a bequest or gift of goods and chattels by will or testament. The person to whom it is given is termed the legatee (legatarius); and every person is capable of being a legatee, unless particularly disabled by the common law or by some statute.

The bequest in no case confers more than an inchoate property on the legatee, which does not become complete until the assent of the executor or administrator with the will annexed, as the case may be, has been given. [EXECUTOR.] But, before such assent, the bequest is transmissible to the personal representatives of the legatee, and will pass by his will.

Legacies are of two kinds, general and specific. A legacy is general when it is so given as not to amount to a bequest of a particular thing, or a particular fund of the testator; a specific legacy is a bequest of a specified thing, or a specific part of the testator's estate. The whole of the estate of a person deceased being liable for the payment of his debts, legacies of both kinds are of course subject to debts: but in case of a deficiency of the estate for the payment of the legacies, the general legatees can only be paid in equal proportion; and they must, as it is technically termed, *abate*. But a specific legatee is not compelled to abate or allow any thing by way of abatement, though his legacy may be taken for the payment of debts, in case the general legacies have all been applied to pay them and there is still a deficiency to meet the demands on the estate of the deceased. Specific legatees may, however, be compelled to abate as against one another. If the part of the testator's estate which is specifically given has been disposed of by the testator in his lifetime, or at the time of his death has ceased to exist in such form as described in his will, the general rule is, that the specific legatee loses his legacy, and is not entitled to any satisfaction out of the general estate: in such case the legacy is said to be adeemed, a term which has been derived from the Roman law, though the word 'adimere' is not there used exactly in this sense. (Dig. 34, 4.) There is also a third description of legacy partaking somewhat of the nature of both kinds already mentioned, as a gift of so much money, with reference to a particular fund for payment. This is called a *demonstrative* legacy, but so far differs from one properly specific, that if the fund pointed out fails on any account, the legatee will be paid out of the general assets; yet it is so far specific that it is not liable to abate in case of deficiency of the general assets.

Legacies may be given either absolutely (*purè*) or upon condition (*sub conditione*), or upon the happening of any contingency; provided it must happen, if at all, within the duration of a life or lives in being at the time of the decease of the testator and twenty-one years afterwards, allowing in addition the period of gestation where the contingency depends upon the birth of a child. Legacies may also be given in such a way that though no condition is expressed in distinct terms, it may be clearly inferred that the testator did not intend his gifts to take effect till a definite time had arrived or a definite event had taken place. When a legatee has obtained such an interest in the legacy as to be fully entitled to the property in it, the legacy is said to be *vested*, and this property may be acquired long before the right to the possession of the legacy accrues. A vested legacy partakes of the incidents of property so far as to be transmissible to the personal representatives of the party entitled to it, or to pass by his will; a legacy which is contingent or not vested is no property at all with respect to the legatee. This distinction of legacies, vested or not vested, seems derived from the Roman law, which expresses the fact of vesting by the words '*dies legati cedit*.'

Formerly, in all cases when a legatee died before the testator, the legacy lapsed, or failed, and went to the person appointed residuary legatee by the testator, or if there was none such, to the next of kin; and lapse might also take place (as already observed with respect to a legacy given to a legatee at a particular time, or upon condition, or

the happening of a contingency) if the legatee died before the appointed time arrived, or if the condition was not performed, or the contingency did not happen. The Wills Act, 1 Vict. c. 26, sect. 33, modified the old rule, and directed that when legacies are bequeathed to a child or other issue of the testator who shall die in his lifetime, leaving issue, and such issue shall be living at the testator's death, the legacies shall not lapse unless a contrary intention appears upon the face of the will, but shall take effect as if the legatee had died immediately after the testator.

The rules by which gifts of legacies are construed are derived from the civil law, or rather are a part of that law, which prevailed in the ecclesiastical courts while those courts had jurisdiction over legacies; for although the Court of Chancery had concurrent jurisdiction with the ecclesiastical courts, yet to prevent confusion it followed the same general rules. If, however, a legacy be charged upon or made payable out of the real estate, then, as the ecclesiastical court had no concurrent jurisdiction, courts of equity are not bound to follow the same rules as to the construction of such gifts as in the case of personal estate.

The questions involved in the law relating to legacies are so numerous that it is quite-impossible even to notice them in an article of this description; and as they are chiefly of a technical nature, the reader is referred to the various treatises on that branch of the law.

Generally speaking an executor cannot be compelled to pay legacies until after the expiration of twelve months from the decease of the testator, and not even then unless the assets should be realised and the debts paid or provided for; but as the rule is only for the general convenience of executors, if it should appear that all the debts of the testator are paid, the executor may be compelled to pay the legacy before the twelve months have expired. It may be stated, however, as a general rule, that legacies are payable twelve months after the death of a testator, and with interest from that time at 4 per cent., unless the testator has made some special provision as to time of payment and interest. The rule as to the twelve months is taken from the Roman law. It has already been stated in this work [EXECUTOR], that an action at law does not lie for a legacy, until after the executor has admitted that he has assets in his hands sufficient to make the payment, or in the case of a specific legacy, has assented to it. But the law may perhaps be more correctly stated thus: Where a specific legacy consists of some determinate chattel, whether real, as a lease for years, or personal, as a particular horse, the legatee, after assent by the executor to the legacy, may take possession of it, or sue for it by action at law; but where the specific legacy consists of money, &c., and in all cases of general and of demonstrative legacies, no action at law lies unless the executor has, for some new consideration beneficial to himself, expressly promised payment. As a general rule, therefore, it may be stated that the remedies by legatees against executors are afforded by the courts of equity. (Roper *On Legacies*; Williams *On Executors*.)

On the subject of legacies (*legata*) under the Roman law, Gaius (ii., 192-255) and the *Digest*, lib. xxx., xxxi., xxxii., '*De Legatis et Fidei commissis*,' are the authorities. This is one of the subjects on which the Roman juriconsults have most successfully exercised their sagacity and diligence.

LEGACY DUTIES. [PROBATE DUTIES.]

LEGATE (from the Latin, *Legatus*). This word had various significations among the Romans. The legates were the chief assistants of the proconsuls and proprætors in the administration of the provinces. The number of legates differed according to the quality of the governor whom they accompanied; their duties consisted in hearing inferior causes and managing all the smaller affairs of the government. They appear to have been chosen and appointed by the governor, though at the first institution of the office it would seem they were selected by the senate, as advisers to the governor, from the wisest and most prudent of their own body. The word *legatus* also signified a military officer who was next in rank to the general or commander-in-chief in any expedition or undertaking, and in his absence had the chief command. (Caesar, '*De Bell. Civ.*' ii., 17.) The word *legatus* is often used to denote a person sent by the Roman state to some other state or sovereign power on matters that concerned the public interest: in this sense the word corresponds pretty nearly to our ambassador or envoy, except that the motives for sending a *legatus*, or legate, seem to have been occasional only, and the legates do not appear ever to have been permanent resident functionaries in a foreign community. Under the emperors those who were sent by them to administer the provinces of which the government was reserved to the emperors, were called legates.

Under the republic the senators who had occasion to visit the provinces on their own business used to obtain what was called a '*legatio libera*,' that is, the title and consideration of a *legatus*, or public functionary, with the sole object of thereby furthering their private interests. These legationes are said to have been called *liberæ*, or free, because those who held them had full liberty to enter or leave the city, whereas all other public functionaries whose duties were exercised beyond the limits of the city could not enter Rome till they had laid aside their functions; or because a senator could not go beyond a certain distance from Rome unless he obtained permission in

the form of a legatio. Cicero, who on one occasion inveighs vehemently against the legatio libera, could defend it when it suited his purpose; and in a letter to Atticus (i. 1) he expresses his intention to visit Cisalpine Gaul in this capacity for the purpose of furthering his election as consul.

At the present day a legate signifies an ambassador, or nuncio, of the pope. They are of the highest class of ambassadors; but are not recognised in Great Britain. [AMBASSADOR; NUNCIO.]

There are several kinds of papal legates, *legatus a latere*, *legatus natus*, &c. Legates a latere are sent on the highest missions to the principal foreign courts, and as governors of provinces of the Roman dominion, thence called legations. Legatus natus is a person who holds the office of legate as incident and annexed to some other office, and is, as we should say, a legate *ex officio*. As this office or title exempted the holder from the authority of the legates a latere, it was earnestly sought after by the bishops. The archbishop of Canterbury was formerly a legatus natus, and in 1100, Guido, archbishop of Vienne, having been sent to England as legate by the pope, was not allowed by Henry I. to exercise his office. There are now three or four German bishoprics permanently invested with the privileges of the office. Legates of a lower rank than cardinals are called *nuncii apostolici*.

LEGEND (from the Latin word *legendum*, a thing to be read) is used commonly in the sense of fabulous or doubtful narratives, such as the exploits of heroes of the middle times between history and fiction, tales of superstition, or other subjects, in which credulity and imposture find free room for exercise. Thus legends have come to signify that which is usually rather matter of tradition than of written evidence. In old authors the word occurs in its simple meaning.

Legend is also used technically to denote the words encircling a coin; to writing on tablets the word *inscription* is applied, which is also used instead of legend where a sentence, instead of encircling, occupies the place of a device on the coin.

LEGER *Lines and Spaces* (Leger, Fr., *light*), in Music, the lines and spaces added to the staff when the notes exceed the ordinary compass. The word is often improperly written *Ledger*.

LEGION. In a Roman consular army each grand division, corresponding nearly to a modern brigade, was so denominated; and the word indicates a selection of the individuals composing such division. The name is still occasionally given to a body of troops consisting of several regiments or battalions, when raised at a particular place or for a particular service.

The strength of a Roman legion varied at different periods. When Romulus divided the citizens of his newly-formed state into three portions or tribes, he also divided the men who were able to bear arms into bodies of 3000 men, and each of these constituted a legion, which was commanded by one or three prefects or tribunes. (Plutarch, in 'Rom.') Servius Tullius, who, by the enlargement of the city, formed a fourth tribe, is supposed to have raised the strength of the legion to 4000 men. About 150 years afterwards, when Camillus marched against Satrium, he had four legions, each of which consisted of that number of men (Liv., i. 22); but, twenty years later, the strength of the legion is stated to have been 5000 foot and 300 horse. (Liv., viii. 8.) This probably continued to be the general establishment of that body of troops, though particular circumstances might cause it to be occasionally increased. Scipio landed in Africa (Liv., xxix. 24) with two legions, each consisting of 6200 men (though the best commentators suppose that 5200 is meant); and while the Roman army was acting against Perseus in Macedon, each legion contained 6000 foot and 200 horse. (Liv., xliii. 12.) Vegetius, who lived in the 4th century, describes the legion (lib. ii., cap. 6) as a body consisting of 6100 foot soldiers, besides 720 horsemen; but he designates this the ancient legion, and his account is probably applicable only to the state of that body in the age of Hadrian and the Antonines. The legion declined under the later emperors, and in the time of Constantine it appears to have consisted of only 1500 men.

During the reign of Augustus twenty-five legions were placed permanently on the frontiers of the empire; and in the time of Hadrian the number of legions composing the Roman army was 30, exclusive of the auxiliaries. Their disposition in Italy and the provinces may be seen in Gibbon, vol. i., ch. 1. The legions were denoted by numbers, and they were further designated by the name of the emperor who raised them, or by the name of the place where they were raised, or where they had distinguished themselves.

The manner in which the soldiers were elected to serve in the legions is fully described by Polybius (book vi., ch. 1), who lived in the age of Fabius and Scipio; and it may be presumed that this was in accordance with the prescribed regulations, which however were only followed when the necessities of the state did not compel the magistrates to dispense with them. When an army consisting of four legions was to be raised, the citizens of the proper ages being assembled on an appointed day in the Capitol, the military tribunes drew out the tribes by lot, and from that which was first called they selected four men of nearly equal age and stature: of these the tribunes who were appointed to the first legion chose one; those who were appointed to the second legion chose another; and so on. Afterwards the whole body of the tribunes chose four other men, and of these the tribunes of the second legion first chose one; those of the third legion then chose another; and so on, the tribunes of the first legion taking the last man of the

four. In like order the election proceeded, till the required number of men was obtained. Polybius states that, in his time, the horsemen were enrolled before the foot soldiers, but that anciently the former were chosen last.

Immediately after the enrolment, the recruits for the legions being made to advance one by one, each was sworn to be obedient to his commanders, and to execute all the orders which he should receive from them to the utmost of his power.

When soldiers were to be raised from the allied cities of Italy, notice appears to have been sent by the consuls to the magistrates of those cities, who then enrolled men in a manner similar to that which was practised at Rome; and, having caused them to be disciplined, sent them to join the army.

On the institution of regular bodies of troops by Romulus, he is said to have divided them (probably each legion) into companies of 100 men, and these were called *Manipuli*, from the bundles of grass which served as standards for the people who accompanied him when he attacked the palace of Amulius. (Aur. Victor, 'Origo Gen. Rom.,' c. 22.) The first mention of a cohort occurs shortly after the expulsion of the kings (Liv., ii. 11); and in the time of Polybius the legion was divided into ten cohorts, each of these into three manipuli (Polyb., b. xi.), and each of the latter into two centuriæ. [COHORT.] A manipulus must have then consisted of 200 men; and at a later period it designated a body of less than the original number. Two *Centuriones* were appointed under each *Manipulus*: each *Centurione* had under him two *Sub-Centuriones*, and a standard-bearer (*Signifer*). Beneath these were the *Decuriones*. Under Hadrian and the emperors immediately following him the cohorts appear to have been of unequal strength. Vegetius states that the first, which was called *cohors milliaria*, and which carried the eagle, consisted of 1500 foot and 132 horsemen; the second, called *cohors quingenaria*, of 555 foot and 70 horsemen; and that the remaining cohorts were nearly of the same strength as the second.

Servius Tullius is said to have divided the military force into five different classes of troops (Liv., i. 43), which were distinguished by their armour; but from the commencement of the republic, or nearly so, the order of battle consisted of three lines of troops, the *Hastati*, the *Principes*, and the *Triarii* (Liv., viii. 8.) The *Velites* (light troops or skirmishers) had no particular station, and except the latter, all the troops, according to Polybius, were armed nearly in the same manner.

The youngest men were selected to act as velites: they were armed with bows or slings, and some of them carried a light javelin. After the time of Marius these ceased to be enrolled as legionary troops, and were chiefly foreigners. Vegetius designates them *Ferentarii*. They wore short swords, and were provided with bucklers of a circular form, about three feet in diameter. The staff of their javelin was two cubits long, and as thick only as a finger; the iron head tapered gradually to a fine point, in order that, being bent at the first discharge, it might be rendered useless to the enemy.

The hastati of all the cohorts were stationed in the first line; the principes formed the second, those of each cohort supporting their own hastati; and the triarii were similarly disposed in the third line to support the principes. All the three classes were completely armed with cuirass, helmet, and greaves; their buckler was 4 feet long and 2½ feet broad, and five arrows were placed in its concavity, to be thrown when necessary. Each man was provided with a long and a short sword, the blade of the former being strong, and made either to cut or thrust; and he carried, besides, two javelins, or *pila*. (Polyb., b. vi.) The only difference in the arms of the three classes seems to have consisted in the size of the *pilum*, those used by the triarii, or veteran soldiers, in the time of Varro being longer and heavier than those of the men in the other lines.

It is supposed that originally the principes were stationed in the first line, and that they were men of the superior classes; from which circumstance, or because they came first into action, they may have acquired their designation.

The front of the legion, when in order of battle, was formed by ten corps of the hastati, each corps being arranged with 16 men in front, and 10 in depth. The second line, or that of the principes, was of the same strength, and was drawn up in the same manner. The line of triarii consisted also of ten corps; but these had only 10 men in front and 6 in depth. Every legionary soldier was allowed five feet in front, and as much in depth, in order that he might be enabled to make free use of his arms.

The cavalry of a Roman legion was divided into ten *turme*, of about 30 horsemen each, who, in order of battle, were drawn up with 8 in front, and 4 in depth. Each legion of the allies had however 600 horsemen; so that the cavalry of a consular army (consisting of two Roman legions and two legions of allies) amounted to 1800 men, who were disposed on the wings of the legion, in one line or two, according to circumstances. The legionary cavalry were furnished with cuirasses and helmets, and they were accompanied by light-armed horsemen, who served as archers.

LEGION OF HONOUR, an order of merit in France, owes its origin to article 87 of the constitution of 1800, which provided that "national recompenses should be bestowed on the warriors who had performed brilliant services," and this principle was organised to some extent by the joint consuls. Napoleon I., when consul for life, established and endowed it early in the year 1802, notwithstanding some

opposition from the legislative body, who, however, gave their sanction on the 19th of May. It was to be a recompense for military and civil services. The order consisted of five divisions: *chevaliers*, of whom the number was unlimited, *officers*, *commanders*, *grand officers*, and *grand crosses*.

The Legion of Honour, though it undoubtedly seemed a forerunner to that new nobility which Napoleon, in after years, collected around his imperial throne, soon became an institution in the highest degree important to his interests, and popular among the nation; and has outlived the fortunes of its founder. Its benefits were appreciated by the Bourbons, who soon discovered that it was the most powerful means they could employ of increasing their popularity, and giving stability to their precarious position. The ordinance of July 19, 1814, however, made some material changes. The right of members of the Legion to vote in the electoral colleges was abolished; the pensions were continued to the titularies already in receipt of them, but only in proportion to the actual income of the body; and future appointments were to convey no such right. On the return of Bonaparte in 1815, he ordered the payment of the arrears, and the restoration of the political privileges of the members. On his downfall the Legion of Honour again felt the resentment of the restored monarch. In Dec., 1816, the pensions of the legionaries were provisionally reduced one-half; but this measure was repealed by the legislative bodies in 1820. Under the two dynasties of Bourbons, the decoration was worn on the breast of an Arago, a Guizot, and a Thiers, with equal honour, and as much applause, as it had been on those of a Ney, a Masséna, and a Lannes. It is to the credit of the French nation that, while no other people are perhaps so much under the influence of military renown, it would be difficult to mention the name of any other country where men of science and literature are more generally esteemed and rewarded. The revolution of 1848, and the elevation of Napoleon III. to the empire, have changed nothing in the institution of the Legion of Honour, except by substituting the tri-color flag instead of those ornamented by fleurs-de-lis.

LEGISLATION. Under this head of legislation, may be considered, 1st. The meaning of the word; 2nd. The distinction between the legislative and executive powers; and 3rd. The difference between jurisprudential and legislative science.

1. *Etymology of the word.*—A magistrate who proposed a law in Rome for the adoption of the assembly of citizens was said *legem ferre* (as we say, to bring a bill into parliament); and the law, if carried, was said to be *perlata*, or simply *lata*. Hence the term *legum lator*, or *legislator*, was used, as synonymous with the Greek νομοθέτης, in the sense of a lawgiver. From *legislator* have been formed *legislation*, *legislative*, and *legislature* (the latter word signifying a person or body of persons exercising legislative power).

Legislation means, therefore, the making of positive law. Positive law [LAW] is made by the person or persons exercising the sovereign power in a community. The end of positive law is the temporal happiness of the community.

2. *Distinction between legislative and executive powers.*—A general command, or law, issued by a sovereign power would be nugatory, if it were not applied in practice to the cases falling within its scope, and if the pains denounced for the violation of it were not inflicted on transgressors. The execution of such general commands or laws is therefore an essential part of the business of a government.

An executive command, or act, of a government, or other authority, is a special command issued, or act done, in the execution of a law previously established by the legislative power. These executive commands or acts are of two sorts, namely, *administrative* and *judicial*; and the distinction between them may (in conformity with modern phraseology) be thus stated. A judicial proceeding is a declaration, by a competent authority, that a person has (or has not) brought himself within the terms of a certain penal provision, or that he has (or has not) a certain legal right or obligation which another disputes with him. An administrative proceeding is for the sake of carrying a rule of law into effect, where there is no question about the legal culpability, or dispute about a legal right or obligation of a person. In an administrative proceeding the government functionary acts, or may act, spontaneously; in a judicial proceeding he does not act until he is acted upon by others. A judge cannot act until his court is (to use the French phrase) *seized*, or *saisi*, with the question; or (to use the language of our ecclesiastical courts) it is necessary "to promote (or set in motion) the office of judge." (Dégérando, 'Institutes du Droit administratif Français,' Paris, 1829.)

The distinction between the making of laws and their execution is too obvious to have been overlooked by the ancient writers on government. The latter subject was treated by them under the head of *magistrates*. (For example, Aristot., 'Pol.,' vi. 8.) The distinction has, however, attracted peculiar attention from both speculative and practical politicians since the beginning of the last century, in consequence of the great importance attributed by Montesquieu to the separation of the legislative, administrative, and judicial powers of government; that is, the exercise of the administrative and judicial functions by officers distinct from the supreme legislative body, and from each other. ('Esprit des Lois,' xi., 6.)

The legislative functions of a government can be distinguished, logically, from its executive functions; but these functions cannot, in

every case, be severally vested in different persons. In every free government (or government of more than one) the legislative bodies exercise some executive functions: thus, in England, the House of Lords is an appellate court in civil cases, and the House of Commons decides in cases of contested elections of its own members. In every form of government the public functionaries, whose primary business is the execution of the laws, exercise a considerable portion of (delegated) legislative power. It is scarcely possible to conceive a body of law so complete as not to require subsidiary laws for carrying the principal laws into execution, and a power of making these subsidiary laws must, to a greater or less extent, be vested in the executive functionaries.

3. *Difference between jurisprudential and legislative science.*—Positive law may be viewed in the two following aspects. First, it may be considered as an organic system, consisting of coherent rules, expressed in a technical vocabulary. Secondly, its rules may be considered singly, with reference to their tendency to promote the happiness of the community; in other words, their expediency or utility. Law viewed in the former aspect is properly the subject of the science of jurisprudence. [JURISPRUDENCE.] Law viewed in the latter aspect is the subject of a department of political science which is generally termed *legislative science*. (Legislation, in strictness, is concerned about the technical form, as well as the utility, of a law; but the term legislative science, as just defined, is sufficiently accurate for our present purpose.)

It is important to bear in mind the distinction, just pointed out, between the scientific or technical excellency of a system of law, and the expediency or utility of the rules of which it is composed. The distinction, however manifest, has been frequently overlooked, even by lawyers. Thus Sir W. Blackstone, in describing the struggle made by the clergy to substitute the Roman law for the common law of England, gives the preference to the latter system on the ground of the imperial government of Rome being despotic. The excellency of a system of law, considered in a scientific point of view, has no connection with the form of the government by which the laws were established. Law may be, and has been, cultivated as a science with admirable success under very bad governments. The scientific cultivation of law in Rome scarcely began until the Empire; and the great legal writers of France lived in times of political anarchy or despotism. A system of law of which the practical tendency may be most pernicious, may have the highest scientific or technical excellency. A code of laws establishing slavery, and defining the respective rights and duties of master and slave, might be constructed with the utmost juristical skill; but might, on that very account, be the more mischievous as a work of legislation. On the other hand, a system of law may be composed of rules having a generally beneficial tendency, but may want the coherency and precision which constitute technical excellency. The English system of law affords an example of the latter case. Owing to the popular character of the legislature by which its rules were enacted or sanctioned, it has a generally beneficial tendency; but considered in a scientific point of view it deserves little commendation. The writings of Mr. Bentham, in like manner, are far more valuable contributions to legislative than to jurisprudential science. The remains of the writings of the Roman lawyers, on the other hand, are of little assistance to the modern legislator, but they abound with instruction to the jurist.

The distinction between the technical excellency of a law and its expediency, or (in other words) between its form and its substance, is also important with reference to the question of *codification*, that is, the making of a code of laws.

The making of a code of laws may involve any one of the three following processes:—1. The formation of a new system or body of laws. 2. The digesting of written laws, issued at various times, and without regard to system. 3. The digesting of unwritten law, contained in judicial decisions and authoritative legal treatises. The ancient codes of law were, for the most part, works of new legislation; such were, for example, the codes of Solon and Draco, the Twelve Tables, the code of Diocles of Syracuse, and others. The *codices* of Theodosius and Justinian afford examples of the digesting of written laws. The Digest or Pandect of Justinian affords an example of the digesting of unwritten law. The French codes were not digests of the existing law of France, either written or unwritten; but they were in great measure founded on the existing law. The same may be said of the Prussian Landrecht. The statutes for consolidating various branches of the criminal law of England, the bankruptcy laws, the customs laws, &c., are instances of the digesting of the written law of England. The specimens hitherto furnished by different commissions of a digest of the English common (or unwritten) law have only been such as to prevent their being thrown into the shape of written law. The digesting of existing law, whether written or unwritten, requires merely juristical ability; the making of new laws requires in addition to the knowledge and skill of the jurist, that ability which we have termed legislative. In other words, the making of new laws requires both attention to their utility or expediency, and technical skill in the composition or drawing of them. Popular forms of government secure a tolerably careful examination of laws, with reference to their expediency; but they do not secure attention to the technical or scientific department of legislation. Indeed nearly all the principal codes of laws have emanated from despotic governments, namely,

the Roman, Prussian, Austrian, and French codes. The difficulty of passing an extensive measure through a popular legislature has been urged by those who have been reproached with failure, as discouraging any attempt at a systematic digesting of the law. But the digest of the law of the state of New York, and other American codifications, afford instances that such difficulty is not insurmountable.

The inconveniences arising from too great prolixity or too great conciseness in the phraseology of laws are stated by Lord Bacon, in the 66th and 67th aphorisms of his eighth book 'De Augmentis.' If an attempt be made, by an enumeration of species, to avoid the obscurity which arises from the use of large generic terms, doubts are created as to the comprehensiveness of the law; for, as Lord Bacon well observes, "Ut exceptio firmat vim legis in casibus non exceptis, ita enumeratio infirmat eam in casibus non enumeratis." ('Ib.,' aph. 17.) On the other hand, vague and extensive terms, if unexplained, are obscure and frequently ambiguous. The best mode of producing a law which shall at once be comprehensive, perspicuous, and precise, probably is, to draw the text of the law in abstract and concise language, and to illustrate the text with a commentary, in which the scope, grounds, and meaning of the several parts of the law are explained. Such a commentary was suggested by Mr. Bentham. ('Traité de Legislation,' tom. iii., p. 284; 'De la Codification,' s. 4.) Doubts will arise in practice respecting the interpretation of the most skilfully drawn laws; and the best guide to the interpretation of a law is an authentic declaration, made or sanctioned by the legislature which enacted it, of its scope or purpose. The want of such a commentary frequently causes the scope of a law to be unknown; and hence the tribunals often hesitate about enforcing laws which may be beneficial. ('Dig.,' lib. i., t. 3, fr. 21, 22.)

It seems scarcely necessary to say that laws ought, where it is possible, to be composed in the language most intelligible to the persons whose conduct they are to regulate. In countries where the great majority of the people speak the same language (as in England or France), no doubt about the choice of the language for the composition of the laws can exist. In countries however where the people speak different languages, or where the language of the governing body differs from that of the people, or where the bulk of the people speak a language which has never received any literary cultivation, a difficulty arises as to the language in which the laws shall be written. Where the people speak different languages, authentic translations of the original text of the laws should be published. Where the language of the governing body differs from that of the people (which is generally the case in newly-conquered countries), the laws ought to be issued in the language of the people. It is comparatively easy for a small number of educated persons to learn a foreign language; whereas it is impossible for the people at large speedily to unlearn their own, or to learn a new tongue. Where the language of the bulk of the community has not received a literary cultivation, the language used by educated persons for literary purposes must be employed for the composition of the laws. Thus in Wales, the Highlands of Scotland, and the west of Ireland, the language of the laws and the government is not Celtic, but English; and in Malta, where the bulk of the people speak a dialect of Arabic, the laws are published and administered in Italian, which is the literary language of the island.

LEGITIMATION. [BASTARD.]

LEGUMIN. *Vegetable Casein.* This body has already been referred to [ALBUMEN] as one of the members of the *albuminoid* or *protein* group of substances. It exists in the seeds of all leguminous plants, but is best prepared from peas or sweet almonds. These are bruised, digested in lukewarm water for two or three hours, strained, reduced to a pulp in a mortar, the mass digested in its own weight of cold water for an hour, the whole thrown upon a cloth filter, and finally pressed. The resulting liquor is then set aside for a short time that starch may deposit, is filtered, and dilute acetic acid added to it cautiously drop by drop. The legumin is thus precipitated in flocks, it is first washed with water, then with alcohol, dried, powdered, digested in ether to separate fatty matter, and finally exposed in vacuo to a temperature of 284° Fahr. till all moisture is got rid of.

Legumin is insoluble in cold alcohol or ether. It is readily soluble in cold water, the solution coagulating on boiling; a trace of alkali, however, prevents the coagulation. Acids also cause the precipitation of legumin from solution, and redissolve it if they are added in excess. Ebullition with dilute sulphuric acid converts it into leucin. A piece of rennet has the same action upon solution of legumin that it has upon milk. Legumin or vegetable casein further resembles the animal casein contained in milk, in the spontaneous curdling of its solution when set aside for some hours, the supernatant liquid or vegetable whey containing lactic acid like milk whey.

According to Dumas and Cahours, legumin contains:—

Carbon	.	.	.	.	.	.	.	50.53
Hydrogen	.	.	.	.	.	.	.	6.91
Nitrogen	.	.	.	.	.	.	.	18.15
Sulphur	}	.	.	.	.	.	.	24.41
Oxygen								
								100.00

Some experimenters, however, find more carbon and less nitrogen; the sulphur appears to be present to the extent of 0.51; and Voelcker finds 2.18 of phosphorus in legumin. By oxidation legumin gives formic, acetic, and other acids of the series $C_nH_nO_4$.

Legumina, like the other members of the albuminoid group, is an important flesh-forming material. [ALBUMEN.]

LEIOGOMME is the name given to a substance possessing the properties of gum, and which is produced by simply exposing starch to a temperature of 300°. It has a brownish-yellow colour, and acts in the same manner as gum, and is extensively used instead of this substance in calico-printing. It is identical with DEXTRIN.

LEIPSIC YELLOW. [COLOURING MATTERS.]

LELEGES. The history of this people is involved in great obscurity, in consequence of the various and almost contradictory traditions which exist concerning them; according to which, they are on the one hand represented as among the earliest inhabitants of Greece, while on the other they are said to be the same people as the Carians. They were probably, as Strabo considers them, a mixed race widely diffused. According to Herodotus, the Carians, who originally inhabited the islands of the Ægean Sea, were known by the name of Leleges before they emigrated to Asia Minor (i. 171); and according to Pausanias, the Leleges formed only a part of the Carian nation (vii. 2, § 4). The Leleges appear, from numerous traditions, to have inhabited the islands of the Ægean Sea and the western coasts of Asia Minor from a very early period. In Homer they are represented as the allies of the Trojans, who inhabited a town called Pedasus, at the foot of Mount Ida; and their king, Altes, is said to be the father-in-law of Priam. ('Il.,' xx. 96; xxi. 86.) They are said to have founded the temple of Hera in Samos (Athen. xv., p. 672, Casaubon); and Strabo informs us that they once inhabited, together with the Carians, the whole of Ionia (vii. p. 331).

On the other hand, in the numerous traditions respecting them in the north of Greece, we find no connection between them and the Carians. According to Aristotle (quoted by Strabo, vii. p. 322), they inhabited parts of Acarnania, Ætolia, Opuntian Locris, Leucas, and Boeotia. In the south of Greece we again meet with the same confusion in the traditions of Megara respecting the Leleges and Carians. Car is said to have been one of the most ancient kings of Megara, and to have been succeeded in the royal power after the lapse of twelve generations, by Lelex, a foreigner from Egypt. (Paus., i. 39, § 4, 5.) Pylus, the grandson of this Lelex, is said to have led a colony of Megarian Leleges into Messenia, where he founded the city of Pylus. (Paus., iv. 36, § 1.) The Lacedæmonian traditions, on the contrary, represent the Leleges as the original inhabitants of Laconia. (Paus., iii. 1, § 1.)

It can scarcely be doubted, from the numerous traditions on the subject, that the Leleges were in some manner closely connected with the Carians; though it seems improbable that they were, according to Herodotus, the same people. The Carians are universally represented as a people of Asiatic origin; while the principal and apparently earliest settlements of the Leleges were on the continent of Greece. With the single exception of the Megarian tradition mentioned above, the Leleges are nowhere represented as foreign settlers. If we might venture to form an opinion upon such a doubtful subject, we should be disposed to regard the Leleges as a people of Pelasgian race, a portion of whom emigrated, at a very early period, from the continent of Greece to the islands of the Ægean Sea, where they became connected with the Carians, and subsequently joined them in their descent upon Asia Minor.

(Kruze's *Hellas*: Wachsmuth's *Historical Antiquities of the Greeks*; Thirlwall's *History of Greece*; *Philological Museum*, No. 1, art. "Anceus.")

LEMMA ($\lambda\eta\mu\mu\alpha$, literally "a thing taken or assumed"), a preparatory proposition borrowed from another subject, or from another part of the same subject, and introduced at the point at which it becomes indispensable. Thus, if in a treatise on mechanics it become necessary to prove certain propositions of geometry, those propositions are lemmas. Many writers use the term as if it applied to any necessary preliminary proposition: thus the seventh of the first book of Euclid is with them a lemma to the eighth. But this destroys the peculiar and ancient signification of the term, which it is desirable to retain, or else to avoid the word altogether.

LEMNISCATA, a curve (first noticed by James Bernoulli) having the form of an 8, but with the upper and lower parts perfectly symmetrical. It is the locus of the point in which a tangent to an equilateral hyperbola meets the perpendicular on it drawn from the centre. If the equation of the hyperbola be $x^2 - y^2 = a^2$, that of the lemniscata referred to the same axes is $(x^2 + y^2)^2 = a^2(x^2 - y^2)$, and its polar equation is $r^2 = a^2 \cos. 2\theta$. If the hyperbola be not equilateral, and its major and minor semi-axes be a and b , the locus above described is still a curve of the same form, and if

$$\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$$

be the equation of the hyperbola, that of the new lemniscata is

$$(x^2 + y^2)^2 = a^2 x^2 - b^2 y^2.$$

A great many different curves might be assigned, having the same form: an instance is $y^2 = mx^2(a^2 - x^2)$.

LEMONS, ACID OF. [CITRIC ACID.]

LEMONS, ESSENTIAL OIL OF. This well-known essence is extracted from the little cells visible on the rind of lemons, by submitting raspings of the fruit to pressure. It may also be obtained by distilling the peel with water, but the product is less agreeable although not so liable to undergo decomposition, owing to the absence of mucilaginous matter.

When pure, essential oil of lemons is colourless and limpid; specific gravity 0.847 at 70° Fahr.; boiling point about 145° Fahr.; soluble in all proportions in alcohol or ether. It is nearly all composed of a hydrocarbon, isomeric with oil of turpentine, CITREN or Citronyl, the boiling point of which is 329° Fahr., and specific gravity 0.857. An oxidised portion is also present, the composition of which has not been determined.

The greater portion of commercial oil of lemons is imported from Portugal and Italy, some however from France. It is very frequently adulterated with oil of turpentine.

LEMONS, SALT OF, a name improperly applied by druggists to binxalate of potash. [OXALIC ACID.]

LENS (Latin for "a small bean"), a name given to a glass, or other transparent medium, ground with two spherical surfaces in such manner as to be generated by the revolution of one or other of the following figures about the axis A B.

(1) is plano-convex; (2) is double-convex; when the radii are equal it is called equi-convex, and when one radius is 6 times the other it is called a crossed lens; (3) is a meniscus; in every such lens the concave side has the larger radius; (4) is plano-concave; (5) is double concave; (6) is concavo-convex.

We shall not here enter upon the laws of optics, but presuming them known, shall collect the principal facts and formulæ connected with the passage of a direct pencil of light, that is, of a pencil whose rays are either parallel to the axis, or converge to or diverge from a point in the axis. We shall follow the notation (for the most part) and formulæ of Mr. Coddington, in his standard work entitled 'A Treatise on the Reflexion and Refraction of Light,' Cambridge, 1829, which contains a most complete investigation of the subject; referring to the work itself for demonstration and extension.

The following figure represents the passage of a pencil of light with parallel rays through a double-convex lens. The rays are not all refracted to a point, but are tangents to a CAUSTIC, which has a cusp at a certain point F, and may be considered with sufficient accuracy as a small portion of a semicubical parabola. If however the aperture of the lens be no considerable portion of a sphere, which is always the case in practice, the rays which pass near the axis are thrown so thick about the point F, that the effect is an image of the extremely distant

point from which the rays come, formed at F. This (for parallel rays) is called the focus of the glass, and its distance from the nearest side of the lens is called the focal distance. The longitudinal aberration of a ray is the distance from the focus at which it passes through the axis, and the latitudinal aberration is the perpendicular distance from the axis at which it passes through a perpendicular drawn through the focus. Thus, in the following figure, FA is the longitudinal, and FB the latitudinal aberration of the ray PQ.

We shall first state the method of finding the focal length of a given lens. Let μ be the index of refraction, or $\mu : 1$ the constant proportion which the sine of the angle of incidence bears to that of refraction (which for plate-glass varies from 1.500 to 1.540; for crown-glass, from 1.525 to 1.563; and for flint-glass from 1.576 to 1.642); and let R and s be the radii of the two sides of the lens with their signs, while r and s are the numerical values of these radii independently of their signs. Also let every convex surface be considered as having a positive radius, and every concave surface a negative one. Let F be the focal distance with its sign, and f the numerical value of the same, it being agreed that the focal distance shall be positive when parallel rays are made to

converge, and negative when they are made to diverge, that is, to proceed as if they came from a point on the same side of the glass as that on which they entered. One formula, upon these suppositions, will embrace all the cases; and that formula is

$$\frac{1}{F} = (\mu - 1) \left(\frac{1}{R} + \frac{1}{s} \right)$$

on the supposition that the central thickness of the lens is inconsiderable. But if this thickness, though small, be large enough to render it necessary to take it into account, let the thickness be called t, and let R be the radius of the side at which the light enters: then either find F from

$$\frac{1}{F} = (\mu - 1) \left(\frac{1}{R} + \frac{1}{s} \right) + \frac{(\mu - 1)^2}{\mu} \cdot \frac{t}{R^2};$$

or correct F, as found from the preceding formula, by subtracting from its algebraical value

$$\frac{(\mu - 1)^2}{\mu} \cdot \frac{F^2 t}{R^2}$$

F being found from the preceding: the result is sufficiently correct.

The focal distance, as determined from the first formula, is the same whether the light enter on one side or the other, but the correction for the thickness depends, as we see, upon the side at which it enters.

The application of these formulæ to the several cases is as follows:— We write the distinctive adjective of the lens so that the first part of the word shall denote the part at which light first enters; for instance, plano-convex, or convexo-plane, according as the light first meets the plane or convex surface.

(1). *Plano-convex*: R is infinite, s = s.

$$\frac{1}{F} = \frac{\mu - 1}{s}, \text{ or } f = \frac{s}{\mu - 1}.$$

(1). *Convexo-plane*: R = r, and s is infinite:

$$\frac{1}{F} = \frac{\mu - 1}{R} + \frac{(\mu - 1)^2 t}{\mu R^2}; f = \frac{r}{\mu - 1} - \frac{t}{\mu}.$$

(2). *Double-convex*: R = r, s = s:

$$\frac{1}{f} = (\mu - 1) \left(\frac{1}{r} + \frac{1}{s} \right) + \frac{(\mu - 1)^2}{\mu} \cdot \frac{t}{r^2}.$$

(3). *Convexo-concave meniscus*: R = r, s = -s, r < s:

$$\frac{1}{F} = (\mu - 1) \left(\frac{1}{r} - \frac{1}{s} \right) + \frac{(\mu - 1)^2}{\mu} \cdot \frac{t}{r^2} = \frac{1}{f}.$$

(3). *Concavo-convex meniscus*: R = -r, s = s, r > s:

$$\frac{1}{F} = (\mu - 1) \left(\frac{1}{s} - \frac{1}{r} \right) + \frac{(\mu - 1)^2}{\mu} \cdot \frac{t}{r^2} = \frac{1}{f}.$$

In all the preceding cases F is positive; or all sharp-edged lenses make parallel rays converge: but in those which follow it will be noted that F is negative, or all flat-edged lenses make parallel rays diverge.

(4). *Plano-concave*: R is infinite, s = -s:

$$\frac{1}{F} = -\frac{\mu - 1}{s}, \text{ or } f = \frac{s}{\mu - 1}.$$

(4). *Concavo-plane*: R = -r, s is infinite:

$$\frac{1}{F} = -\frac{\mu - 1}{r} + \frac{(\mu - 1)^2}{\mu} \cdot \frac{t}{r^2}; f = \frac{r}{\mu - 1} + \frac{t}{\mu}.$$

(5). *Double-concave*: R = -r, s = -s:

$$\frac{1}{F} = -(\mu - 1) \left(\frac{1}{r} + \frac{1}{s} \right) + \frac{(\mu - 1)^2}{\mu} \cdot \frac{t}{r^2};$$

$$\frac{1}{f} = (\mu - 1) \left(\frac{1}{r} + \frac{1}{s} \right) - \frac{(\mu - 1)^2}{\mu} \cdot \frac{t}{r^2}.$$

(6). *Convexo-concave*: R = r, s = -s, r > s:

$$\frac{1}{F} = (\mu - 1) \left(\frac{1}{r} - \frac{1}{s} \right) + \frac{(\mu - 1)^2}{\mu} \cdot \frac{t}{r^2};$$

$$\frac{1}{f} = (\mu - 1) \left(\frac{1}{s} - \frac{1}{r} \right) - \frac{(\mu - 1)^2}{\mu} \cdot \frac{t}{r^2}.$$

(6). *Concavo-convex*: R = -r, s = s, r < s:

$$\frac{1}{F} = (\mu - 1) \left(\frac{1}{s} - \frac{1}{r} \right) + \frac{(\mu - 1)^2}{\mu} \cdot \frac{t}{r^2};$$

$$\frac{1}{f} = (\mu - 1) \left(\frac{1}{r} - \frac{1}{s} \right) - \frac{(\mu - 1)^2}{\mu} \cdot \frac{t}{r^2}.$$

* These results are only nearly true.

If, in any of the preceding, the term involving t be left out, we have the common approximate mode of determining the focus. We now come to the formulæ for determining the aberration in the case of a direct pencil of parallel rays.

Let MN , in the third figure (the perpendicular distance from N to the axis will do equally well) be $=y$; then AF is determined by the following formula:—

$$K = -\frac{\mu-1}{2\mu^2} \left\{ \frac{1}{R^3} + \left(\frac{1}{s} + \frac{\mu+1}{F} \right) \left(\frac{1}{s} + \frac{1}{F} \right)^2 \right\} F^2 y^2$$

where R is the radius of the surface which the light first meets. The algebraical value of MA in the figure is $F+K$, where F is supposed corrected for the thickness. If we assume

$$x = \frac{s-R}{s+R}; \text{ then } K = -\frac{\Lambda y^2}{8F};$$

where Λ stands for

$$\frac{1}{\mu(\mu-1)} \left\{ \frac{\mu+2}{\mu-1} x^2 - 4(\mu+1)x + \frac{3}{\mu-1} \right\}$$

The following are the results, assuming $\mu = \frac{3}{2}$, which is near enough (if the material be glass) for determining this correction. This supposition gives (x being the numerical value of x , independently of sign)

$$K = -\frac{7x^2 - 10x + 10}{6} \cdot \frac{y^2}{F}$$

$$(1). \text{ Plano-convex: } x = -1 \quad K = -\frac{9}{2} \frac{y^2}{F}$$

$$(1). \text{ Convexo-plane: } x = 1. \quad K = -\frac{7}{6} \frac{y^2}{F}$$

(2). Double-convex: light entering at the more convex side:

$$x = \frac{s-r}{s+r}, \quad K = -\frac{7x^2 - 10x + 10}{6} \cdot \frac{y^2}{F}$$

(2). Double-convex: light entering at the less convex side:

$$x = \frac{r-s}{r+s}, \quad K = -\frac{7x^2 + 10x + 10}{6} \cdot \frac{y^2}{F}$$

(3). Convexo-concave meniscus:

$$x = \frac{s+r}{s-r}, \quad K = -\frac{7x^2 - 10x + 10}{6} \cdot \frac{y^2}{F}$$

(3). Concavo-convex meniscus:

$$x = \frac{r+s}{r-s}, \quad K = -\frac{7x^2 + 10x + 10}{6} \cdot \frac{y^2}{F}$$

(4). Plano-concave: same * as plano-convex.

(4). Concavo-plane: same as convexo-plane.

(5). Double concave, light entering at the more concave side: same as double convex, light entering at the more convex side.

(5). Double concave, light entering at the less concave side: same as double convex, light entering at the less convex side.

(6). Convexo-concave: same as concavo-convex meniscus.

(6). Concavo-convex: same as convexo-concave meniscus.

Throughout these formulæ the sign of K is opposite to that of F , since $7x^2 + 10x + 10$ must always be positive. Hence the point A always lies between the points M and F (third figure). If the point N be placed as high as possible, that is, if y be what is called the semi-aperture of the lens, then K is the aberration of the extreme ray. It appears also that the longitudinal aberration varies directly as the square of the semi-aperture, and inversely as the focal distance.

The aberration is least for a given aperture and focal length, when $x = \frac{5}{7}$, which gives $s = 6R$, requiring a double-convex or double-concave lens, in which the radius of the side on which light enters is one-sixth of the other. The convex lens of this kind is what opticians call the crossed lens. The co-efficient of $y^2 \div F$ is $-\frac{15}{14}$.

The latitudinal aberration at the focus (as determined with the correction for the thickness) is $yK \div F$, or (neglecting the sign)

$$\frac{1}{8} \Lambda \frac{y^3}{F^2}; \text{ for glass } \frac{7x^2 - 10x + 10}{6} \frac{y^3}{F^2}$$

But if we observe the rays in the second figure (and the same may be clearly seen in a beam of sun-light thrown into an otherwise dark room through a convex lens) we shall see that the luminous space is bounded by a surface of revolution which narrows and afterwards

* That is, the aberration has the same formula: but it must be noted that r has different signs in the two lenses.

spreads again, as in this diagram. The smallest circle (at G) is called the circle of least aberration, and is determined as follows:—Its

centre is nearer to the glass than the focus (corrected for the thickness) by three-fourths of the longitudinal aberration of the extreme ray; and its diameter is one-half of the lateral aberration of the extreme ray. If then we measure from the corrected focus, we find for the distance of the circle of least aberration (neglecting its sign) from this focus,

$$\frac{3\Lambda y^2}{32F}; \text{ for glass } \frac{7x^2 - 10x + 10}{8} \cdot \frac{y^2}{F};$$

and for the diameter of this circle,

$$\frac{\Lambda y^3}{16F^2}, \text{ for glass } \frac{7x^2 - 10x + 10}{12} \frac{y^3}{F^2}.$$

The correction for the thickness, to be subtracted from F as determined by the first equation of all, is

$$-\frac{1}{4\mu} (x+1)^2 \cdot t; \text{ for glass } -\frac{1}{6} (x+1)^2 \cdot t;$$

which is always algebraically subtractive, whatever the sign of F may be. The following table exhibits this correction, the distance of the circle of least aberration, and its diameter, for the cases above noted. The description of the lens is in the first column, and x stands for plane (or plano), c for concave, and inverted c for convex. The sign of the surface which the light first meets is placed first. Where a great and small letter meet, the small letter shows the side which has the less curvature, or the larger radius.

$$\alpha = 7x^2 - 10x + 10 \\ \beta = 7x^2 + 10x + 10$$

Lens.	x or x .	Correction for thickness.	Distance of Circle.	Diameter of Circle.
IC and IC	$x = -1$	0	$\frac{27}{8} \frac{y^2}{F}$	$\frac{9}{4} \frac{y^2}{F^2}$
CI and CI	$x = 1$	$\frac{2}{3} t$	$\frac{7}{8} \frac{y^2}{F}$	$\frac{7}{12} \frac{y^3}{F^2}$
Co and Oc	$x = \frac{s-r}{s+r}$	$(x+1)^2 \frac{t}{6}$	$\frac{\alpha}{8} \frac{y^2}{F}$	$\frac{\alpha}{12} \frac{y^3}{F^2}$
cO and oC	$x = \frac{r-s}{r+s}$	$(x-1)^2 \frac{t}{6}$	$\frac{\beta}{8} \frac{y^2}{F}$	$\frac{\beta}{12} \frac{y^3}{F^2}$
Cc and Oc	$x = \frac{s+r}{s-r}$	$(x+1)^2 \frac{t}{6}$	$\frac{\alpha}{8} \frac{y^2}{F}$	$\frac{\alpha}{12} \frac{y^3}{F^2}$
oC and Cc	$x = \frac{r+s}{r-s}$	$(x-1)^2 \frac{t}{6}$	$\frac{\beta}{8} \frac{y^2}{F}$	$\frac{\beta}{12} \frac{y^3}{F^2}$

We have judged it more useful to collect what we may call the critical formulæ, by which the fitness of a lens for any given purpose may be estimated, than to enter upon explanations of optical principles in an isolated article. We shall now give the formulæ only, omitting the detail of cases, when the pencil of rays is not parallel, but proceeds from a point in the axis.

Let u be the distance of the focus of the entering pencil from the surface whose radius is R , and v the distance of the focus of the rays on the other side from the surface whose radius is s ; u being negative when the entering pencil is convergent, and v negative when the emergent pencil is divergent. Let F be the distance of the uncorrected focus of parallel rays from the surface of emergence, determined as before. Then, if the thickness of the lens be inconsiderable, v is determined from u by the equation,

$$\frac{1}{v} + \frac{1}{u} = \frac{1}{F} = (\mu-1) \left(\frac{1}{R} + \frac{1}{s} \right);$$

v representing the solution of this equation, the more correct value, taking the thickness t into account, is

$$v = \left(\frac{\mu-1}{R} - \frac{1}{u} \right)^2 \frac{t v^2}{\mu}.$$

$$\text{Let } x = \frac{s-R}{s+R}; \quad w = \frac{v-u}{v+u};$$

then the above correction for the thickness is

$$v = \left(\frac{x-w}{1-w} \right)^2 \cdot \frac{t}{\mu};$$

and assuming λ to stand for

$$\frac{1}{\mu(\mu-1)} \left\{ \frac{\mu+2}{\mu-1} x^2 + 4(\mu+1)wx + (3\mu+2)(\mu-1)w^2 + \frac{\mu^3}{\mu-1} \right\}$$

the longitudinal aberration is

$$-\frac{\lambda}{8} \frac{v^2}{F^2} \frac{y^2}{F}; \text{ or } -\frac{\lambda}{2(1-w)^2} \frac{y^2}{F};$$

which must be algebraically applied to the value of v (corrected for thickness). The latitudinal aberration is

$$\frac{\lambda}{8} \frac{v}{F} \frac{y^3}{F^2}; \text{ or } \frac{3\lambda}{4(1-w)} \frac{y^3}{F^2}.$$

The distance of the least circle of aberration from the corrected focus is

$$-\frac{3\lambda}{32} \frac{v^2}{F^2} \frac{y^2}{F}; \text{ or } -\frac{\lambda}{8(1-w)^2} \frac{y^2}{F};$$

and the diameter of the same circle is

$$\frac{\lambda}{16} \frac{v}{F} \frac{y^3}{F^2}; \text{ or } \frac{\lambda}{8(1-w)} \frac{y^3}{F^2}.$$

When two or more lenses are placed close together, in finding the approximate focal distance, uncorrected for the thicknesses, they may be considered as one lens, whose focal distance has a reciprocal equal to the sum of the reciprocals of the focal distances of the component lenses. Sir J. Herschel has proposed to call the reciprocal of the focal distance the *power* of a lens; in which case it would be said that the power of a compound lens is equal to the sum of the powers of the simple lenses.

For more complicated cases, see the work of Mr. Coddington, already cited.

Hitherto we have supposed the surfaces of the lens to be either plane or spherical, as is usually the case. Lenses are, however, sometimes made with cylindrical surfaces. If the two surfaces of a thin lens are portions of cylinders of equal radii, with their axes perpendicular to each other, and both surfaces are convex or both concave, the lens will have the same general effect as an equi-convex or equi-concave lens, the radius of the spherical surfaces of which is double that of the cylindrical surfaces of the former lens. Such cylindrical lenses may sometimes be advantageously employed instead of spherical lenses. Thus, when a large lens is held at some distance from the eye, and used for viewing an engraving or photograph, the distortion with a cylindrical lens is of a less unpleasant character than with a spherical lens.

But there is a further use of lenses with one or both surfaces cylindrical in correcting a defect of the eye, by no means uncommon, which consists in the length of sight being, so to speak, different in different planes passing through the axis of the eye, and which sometimes is so great as to cause very serious inconvenience. Its existence is known by directing the eye to the clouds, and holding a small needle-hole in a blackened card at first close to the eye, and then moving it off to arm's length, the eye all the while being adapted for vision of a distant object. The indistinct mirage of the hole ought to remain circular at all distances; but when this defect exists, the mirage passes successively into two lines in rectangular directions, unless the eye be too long-sighted, in which case the lines are seen by adapting it to vision of a nearer object, or if that be not enough, using an ordinary convex lens. The defect, when it exists, may be corrected by means of spectacles having one surface at least of the lens for the defective eye cylindrical. See papers in the 'Cambridge Philosophical Transactions,' vol. 2, p. 267, and vol. 8, p. 493; also 'Report of the British Association' for 1849, p. 10.

LENT (in Latin, *Quadragesima*), a time of mortification, commemorative of the miraculous fasting of our Saviour in the Desert; used as a preparation for Easter, and beginning on Ash Wednesday. The Saxon term was *Lencten*, implying Spring, the season when the day increases in length, about the commencement of which this fast, which is a moveable one, usually falls: it is in fact the Spring-Fast.

In the ancient Latin Church, Lent consisted only of thirty-six days: the four additional days were added by Pope Gregory in the 9th century.

Some assert that this fast was first instituted by the Apostles. Such was the opinion of St. Jerome, St. Leo, St. Augustine, and others. Tertullian speaks of it as of long standing in his time: though some writers date it as low as the 3rd century. It was first observed in England by our Saxon ancestors in 640, by order of Ercombert, King of Kent.

(Wheatley *On the Common Prayer*, 8vo, London, 1741; Brady's *Clavis Calendaria*.)

LENTO (Ital., *slowly*), a term in music equivalent to *Largo*.

LEO (the Lion), a constellation of the ZODIAC, which commemorates the Nemean lion killed by Hercules in the mythology of the Greeks. It is surrounded by Ursa Major, Leo Minor, Cancer, Hydra, Sextans, Virgo, and Coma Berenices. A line drawn through the pole star and

the lowest of the four in the Great Bear (or γ) passes through Deneb (or β Leonis); and a line drawn through the bright star Regulus (or α Leonis) of the first magnitude and Deneb passes nearly through Arcturus. The principal stars are as follows:—

Character.	No in Catalogue of Flamsteed.	No. in Catalogue of British Association.	Magnitude.

LEONINE VERSES, a kind of measure much in fashion during the middle ages. It consists properly of the Latin hexameter, or hexameter and pentameter rhymed. No less than ten varieties in the fall of the rhymes are counted; but that which is by far the most common is when the cæsure on the fifth syllable rhymes with the end of the line, as for example:—

"En Rex Edvardus, debacchans ut Leopardus."

There is an example of a modern attempt at Leonine verses in Parnell's translation of a passage in the 'Rape of the Lock,' beginning,

"Et nunc dilectum speculum pro more reiectum."

The rhymes appear universally to be dissyllabic. The classical metre is however not essential. We find in the ancient hymns of the Roman Catholic Church the rhythm of modern versification:—

"Quid sum miser tunc dicturus,
Quem pratorum rogaturus,
Cum vix justus sit securus?"

Or in the famous song of Walter de Mapes, archdeacon of Oxford in the time of Henry II.:—

"Mihi est propositum in taberna mori,
Vinum sit appositum morientis ori,
Ut dicant, cum venerint Angelorum chori,
Deus sit propitius huic potatori."

The term is said to be derived from Leoninus, a monk of the 12th century, the reputed inventor of this mode of composition, which however is shown to go back as far at least as the 3rd century. It went out of fashion with the revival of classical learning.

LEPIDINE. [LEUCOLINE.]

LEPRA (the Greek word *λεπρα*, scabiness), an affection of the skin, of the order Squamæ, or scaly diseases, of Willan and Bateman. It is characterised by an eruption of circular spots of inflamed skin covered with scales, varying from the size of a pin's head to that of a shilling or even a half-crown piece, occasionally mixed with large irregular patches formed by the coalescing of the borders of several contiguous spots. The scales in this affection possess a peculiar character, by which it is distinguished from pityriasis and psoriasis, other diseases of the same order. From the surface of the inflamed spots a diseased cuticle is produced, which concretes into thickish crusts or scales of a glistening white silvery appearance, and from being secreted more abundantly towards the circumference a rounded and elevated form is given to the outer margin, whilst the centre is left almost or entirely free from scale. The whole is surrounded by a slight areola of redness. In the early stage of the disease, and in the small spots, the inflamed skin, which is slightly raised above the surrounding parts, possesses only a thin scaly covering; and in the larger patches, formed by the coalescence of several spots, the characteristic appearances became somewhat confused; still, on careful examination, the elevated margin, circular outline, and central free spot may more or less be recognised.

This disease generally affects young people from the age of puberty up to thirty, and appears to occur more frequently in women than in men. Sometimes the whole body becomes affected by it, even the face and scalp, but more commonly it is confined to the limbs, and is observed especially on the skin below the knee and elbow, in which situations its true characters are generally most marked. The health of persons affected with this disease is but little disturbed, the accession of the eruption alone being preceded by headache and slight febrile disturbance. It is generally tedious of cure, recurring periodically in some constitutions, whilst in others it will continue for two or three years. Most frequently it arises without any assignable cause; occasionally it has appeared to be dependent upon suddenly suppressed cutaneous transpiration from persons drinking cold water when overheated.

This disease must not be confounded with the leprosy of the sacred and ancient writers, a term which appears to have been used to express any loathsome affection of the skin, or, as some imagine, to have referred to the disease described in the present day under the term Elephantiasis. [ELEPHANTIASIS.]

The treatment of lepra should consist in the administration of alterative and depurative medicines. Gentle purgatives, iodide of potassium, arsenic, quinine, and iron, may be given according to circumstances. Externally, the preparations of tar and creasote have been found of most benefit.

LEPROSY. [LEPRA; SKIN, DISEASES OF THE.]

LEPUS (the Hare), one of the old constellations, said by Hyginus to be in the act of running from Orion's dog, which is the greater dog, according to some, and the lesser, according to others. It is situated directly under Orion. The principal stars are as follows:—

Character.	No. in Catalogue of Flamsteed.	No. in Catalogue of British Association.	Magnitude.
ϵ	2	1575	4
β	9	1715	3
α	11	1741	3

θ	18	1959	4

LETHARGY, a state of unnaturally deep and prolonged sleep, a condition intermediate between the sleep of health and complete coma. If not the result of unusual fatigue, it is often an alarming symptom, indicating congestion of the brain, and a disposition to apoplexy, or even an impending attack of that disease. [APOPLEXY; COMA; SLEEP.]

LETTER OF CREDIT. [CREDIT, LETTER OF.]

LETTER or POWER OF ATTORNEY is an instrument by which one person authorises another to do some act for him; it may be used in any lawful transaction, as to execute a deed, to collect rents or debts, to sell estates, &c. The authority must be strictly pursued, for the principal is only bound by the acts of his agent to the extent to which the letter of attorney authorises him to proceed, and if the agent goes beyond his authority he is personally liable to the party with whom he contracts. The power authorising an attorney or agent to do some particular act impliedly includes an authority to do whatever is incident to that act; as for instance, a power to demand and recover a debt authorises the arrest of the debtor in all cases where it is permitted by law. But a power to receive money and to give releases, or even to transact all business, does not authorise the attorney to negotiate bills received in payment. In fact all written powers, such as letters of attorney or letters of instruction, receive a strict interpretation; the authority never being extended beyond that which is given in terms, or is absolutely necessary for carrying the authority so given into effect. An attorney, unless power be specially given him for that purpose, cannot delegate his authority or appoint a substitute, and, generally speaking, the words of general authority usually inserted in letters of attorney, after giving the particular authority, do not enlarge it.

The authority must be executed during the life of the person who gives it, as the act done is considered to be in every respect his act, and a power to do an act is therefore considered as at once revoked by the death of the person giving it.

Powers of attorney may be given either in separate instruments, or in deeds relating to other matters; the second form is usually followed where the instrument forms part of a security for money, as where a chose in action is assigned either as a security for money or to an actual purchaser. The deed of assignment contains a power of attorney authorising the assignee to sue in the name of the assignor. Powers of attorney are generally executed under hand and seal, and where they contain an authority to bind the principal by deed, it is essential that they should be so executed. When the agent signs any instrument which is to bind his principal, he must sign it in the name of the principal, and not in his own name.

A power of attorney, unless it be given as a security, is revocable at pleasure, either by the personal interference of the principal or by his granting a new power to another person. But if the power has been

given as a security, or as it is sometimes called, is coupled with an interest, it is not revocable. Though it has been decided that a power of attorney coupled with an interest is revoked by the death of the grantor, yet if it authorise the agent to act in the name of the grantor, his executors, &c., it may be held that such a power, when given as part of a security, is not revoked by the death of the principal, and that the assignee of his interest has power to do the acts necessary to render his security available in a court of law, in the name of the representatives of the assignor. At all events a court of equity would interfere in favour of the assignee.

A letter of attorney is also in general revoked by the bankruptcy of the principal, unless it is coupled with an interest.

LETTERS-PATENT (in Law), the king's letters, sealed with the great seal. These grants, says Blackstone (2 'Comment.' p. 349, Mr. Kerr's Ed.), whether of lands, honours, liberties, franchises, or anything else that can be granted, are contained in charters or letters-patent, that is, open letters, *literæ-patentes*. They are so called because they are not sealed up, but open to view, with the great seal pendant at the bottom, and are usually directed or addressed by the king to all his subjects at large. Letters-patent, in the time of Queen Elizabeth, as well as in several preceding reigns, were not unusually obtained for purposes of mere monopoly.

They are now frequently granted under the royal authority as the reward of ingenuity, and are in some cases the only means by which a man can secure any compensation for a discovery, or for the labour and expense which he may have employed in perfecting an invention. The consideration of the legal rights of patentees, and of the modes in which they may be acquired and secured, properly belongs to the head of PATENTS. At present it may be sufficient to refer the reader to Collier's 'Essay on the Law of Patents for New Inventions, to which are prefixed two chapters on the general history of monopolies, and on their introduction and progress in England to the time of the Interregnum,' 8vo., Lond., 1803; to Hand's 'Law and Practice of Patents for Inventions,' 8vo., Lond., 1808; Godson's 'Practical Treatise on the Law of Patents,' 8vo., Lond., 1823, with the 'Supplement,' 8vo., Lond., 1832; and Rankin's 'Analysis of the Law of Patents,' 8vo., Lond., 1824. The Patent Law Amendment Act 1852, now regulates the terms upon which letters patent for inventions are granted. See Mr. Kerr's 'Blackstone,' vol. 2, p. 417.

Many letters-patent have been granted by the king to the founders of schools and other charitable endowments, empowering the donor to make rules and ordinances for the government of his charity, and constituting into a body corporate those persons and their successors whom the founder should choose or nominate.

LETTERS, THREATENING. [THREATS.]

LETTUCE (the *Lactuca sativa*, or garden lettuce) is one of the principal kinds of vegetables used for salads, and it also forms an ingredient in several kinds of soup. It has been introduced and cultivated in this country for nearly three centuries, but, like many other domesticated plants, its origin is unknown. The names of several of its varieties indicate their having come to us from the Greek Archipelago and the coast of the Lavant; and one of the two divisions into which the numerous varieties of lettuces are usually classed, termed *Cos lettuces*, derives its name from the island of Cos, the modern Stanco. This division includes those of an erect oblong form of growth. The other division, which comprehends those of a roundish, flattened, or spreading form, is termed that of *Cabbage lettuces*.

The excellence of lettuces consists in their being crisp and tender; their growth should therefore be so conducted as to sustain no check or interruption. If their quick vegetation be stopped by such causes as excessive drought, over-crowding in the seed-bed, or improper transplanting, they will in consequence either run to seed or become tough, and their juices at the same time will acquire an acrid quality.

The ground intended for the seed should be fresh dug, rich, and mellow. The principal summer crop should be sown in March and April, and the seed lightly covered. A seed bed 4 ft. by 10 ft. will require a quarter of an ounce of seed, which ought to produce about 400 plants. If the plants are intended to attain their full perfection where sown, they must be thinned out to distances of 9 inches square, in the case of the small cabbage varieties, and the larger sorts should be allowed at least a foot each way. In transplanting, the above distances are likewise applicable and the operation should be performed, if possible, in cloudy weather; but at all events it must be done before the plants are too old or are in the least over-crowded; for when they are drawn, or their stems have once commenced lengthening, which, in dry weather, will sometimes happen whilst they are yet in a small state, it is useless to transplant them. It is of importance that the soil in which they are grown be neither too wet nor too dry. Where the breadth to be planted is not so great as to render the expense of labour an object of consideration, instead of making holes for the plants with a dipper, it is better to form a small trench, with a perpendicular cut next the line, against which the roots are to be disposed without bruising. Water should be given, but not at any one time to excess; nor merely at the root of each plant, but over the whole of the ground.

The *Cos* lettuces require to have their leaves tied together moderately close, with a strip of matting, for the purpose of assisting their blanch-

between them; and the operation is to be continued to the end of the line on which the profile is required. It is customary to insert the heights Bn , Cq , &c., in a column headed *Fore-sights*, in a sort of field-book, and the heights Am , Bp , &c., in a collateral column headed *Back-sights*. The difference between the sums of the numbers in these two columns will be equal to the height of one extremity of the line above the other.

But it is very generally the practice, with the view of diminishing the risk of error arising from the imperfection of the instrument, to execute a sort of double levelling. This consists in placing the spirit-level successively at each of the two stations, as y and z , and having, by the screws, adjusted the telescope as before, let tv be the horizontal line at y , and wx that at z ; then, the heights zv and yx being obtained by means of the staff set up successively at each opposite station, it may be easily proved that half the difference between them will be equal to the height of the ground at one point, as x , above that at the other. This is however strictly correct only when the staves at y and z are considered as parallel to one another; but the error arising from their being in the direction of the earth's radii is quite insensible in any of the ordinary operations of this nature.

In using either of these methods, therefore, no correction on account of the earth's curvature is necessary; but when, from any circumstances, the spirit-level cannot be placed nearly midway between every two stations, and particularly when it can be placed only at one station, as y , the difference between the height zv of the visual ray at one station, and yt , the height of the instrument at the other, will not, on account of the earth's curvature, be the correct relative heights of the ground at the two stations. For, let yz be an arc of the earth's surface, supposed to be spherical; let also yt , zv , be in the direction of its radii, and let xy be a tangent to the curve at y : then tv being parallel to xy , the difference between zv and yt , or vy (which may be considered as equal to yt), will be zy , the apparent height of y above z ; whereas the true height should be zz . Now, from the known magnitude of the earth, the distance yz , between the tangent xy and the arc, can easily be computed when yz or yz is of any given length. If this length is equal to 100 yards, we shall have $yz=0.02$ inches. Consequently, in a series of operations, carried on in the manner above described, with station lines not exceeding 100 yards in length, the error in the relative heights at the end of one mile would be little more than one-third of an inch.

On ascending or descending a steep hill, no other method can be adopted than that of placing the instrument at one extremity of the station-line and the staff at the other; but as these lines are then necessarily very short, the deviation above mentioned need not be regarded.

In the determination, on uneven ground, of the length of a base-line for the trigonometrical survey of a country, the relative heights of the ground, as at A , B , C , &c., when found as above, serve for the reduction of the measured hypotenusal lines AB , BC , &c., to the corresponding horizontal lines mn , pq , &c.; these being comparatively short, are then considered as circular arcs, and each is separately reduced to an arc of the earth's surface at the level of the neighbouring seas by subtracting from it the term $\frac{h}{r}$, which is found from the proportion between the

arcs and radii in the similar sectors. Here A is the horizontal line or arc, as, mn ; r is the radius of the earth's curvature at the level of the sea, and h is the height of the ground at A , B , &c., above that level.

The profile of the ground is usually expressed on paper, in portions of any convenient length, for the purpose of enabling the engineer to determine the depths of his excavations, or the heights of the masses of earth to be raised, when it is proposed to execute a canal or road. A right line being drawn to represent one parallel to the horizon, and passing through the highest or the lowest point of the natural ground, the heights or depressions of the remarkable points, as A , B , &c., with respect to such line, are obtained by additions or subtractions from the numbers in the field-book, and are, by a proper scale, set out from that line on others drawn perpendicularly to it at intervals equal to the horizontal distances between the same points. The series of points thus obtained, being joined by hand or otherwise, give the figure of the required vertical section of the ground. In general, for the sake of distinctness, the scale by which the heights are set out is greater than that of the horizontal distances between the points.

When the difference of level only between two places is required, a rectilinear direction from one to the other is not necessarily that in which it is most convenient to perform the operation: a circuitous route is preferable when it presents fewer impediments from woods or marshes, or when the inequalities of the ground are of less magnitude.

Among the operations of levelling, which, within a few years, have been performed on an extensive scale, may be mentioned the series of levels taken across the lands between the Black and the Caspian seas; and between the latter and the lake Aral, for the purpose of determining the relative heights of those waters: the series which, during the expedition of Colonel Chesney, were taken from Iskanderun on the Mediterranean to Birehjik on the Euphrates; and near the Persian Gulf, between the latter river and the Tigris. To these may be added the extensive lines levelled in England and on the Continent for the several railways which have been executed or are in progress;

and the important work executed under the auspices of the British Association, in order to determine the difference between the levels of the waters in the English and Bristol channels. The levels taken by Colonel Lloyd across the Isthmus of Darien, and those taken by the French engineers across the Isthmus of Suez, may also be referred to, although in both cases the results obtained have subsequently been called in question.

LEVER (*levare*, to lift up), the name of a common mechanical instrument, consisting of a simple bar of wood or metal, by fixing one point of which, called the *fulcrum*, a pressure at the end more distant from the fulcrum is made to counterbalance a larger pressure at the nearer end; or if both ends be equally distant from the fulcrum, equal pressures are made to balance each other. [BALANCE.]

The lever, considered as a machine, would require no further notice than a reference to the article POWER for the correction of a mistake incident to the conception of this and other machines. But as one of the fundamental principles of mechanics receives its most simple form in its application to the common lever, this instrument assumes a degree of theoretical importance which will justify some discussion of the subject: and the principle of the lever, which is often confounded with the lever itself, must be explained. Thus when it is said in popular writings on mechanics that all machines are reducible to the lever and the inclined plane (an assumption of a startling character if we consider, for instance, the works of a common watch) it is meant that every mode of communicating or relieving pressure is explicable upon the principle of one or other of those machines.

The first explanation of the lever was given by Archimedes, and that in so simple a manner, that while his method has always been the best for a popular view of the subject, it has never been surpassed, or even equalled, in rigor or purity, considered as a foundation for the science of STATICS.

It assumes two principles; firstly, that when a system is in equilibrium, the state of rest will not be disturbed if additional pressures, such as compensate each other, and would by themselves produce no motion, be introduced or removed; secondly, that when a weight is made to rest by being attached to an immoveable point (say it is suspended by a string) the point or pivot of suspension undergoes a pressure equal to the weight of the system, whatever may be the form of that system, or the disposition of its parts. Every science must be founded upon some axiomatic assumption; and perhaps there is none

which is better entitled to preference than the fact that a given weight, say a pound, suspended by a string, exerts the same pressure on the string whatever its shape may be; namely, a pressure equal to the weight of the body. This being premised, a cylindrical or prismatic bar of uniform material will necessarily rest if a pivot be passed through its middle section at A : since there is no reason why it should preponderate on either side. Divide the bar into two parts, BC and CD , of which K and L are the middle points. At K and L suspend weights equal to the weights of BC and CD ; but at the same time apply counterpoises of equal weight acting over fixed pulleys G and H : so that the new forces being such that each pair would be in equilibrium, they would not affect the equilibrium already established by means of the equality of the parts of the bar on each side of A . Now, equilibrium existing, we are at liberty to remove any forces which equilibrate each other, such as are the upper v and the weight of BC ; such also as are the upper w and the weight of CD . For BC , if detached, would exert on the string which goes over the pulley G a pressure neither more nor less than its own weight (which is v); and CD , if detached from the pivot and from BC , would exert on the string of the pulley H a pressure equal to its own weight, or to w . But when these pairs are removed, there remain only the lower weights v and w ; the substance and rigidity of the lever being retained to connect them, though its weight is removed or counterpoised. And KL , being the sum of the halves of the parts, is equal to half of the whole length, or to BA : take away the common part AK , and there remains BK , equal to AL , or KC equal to CL ; also AK is equal to CL . Also v is to w in the proportion of BC to CD , or of KC to CL , or of AL to AK ; that is, the weights v and w balance each other when they are inversely as their distances from the fulcrum A .

It only remains to show that no other weight except v , proportioned to w as above, will counterbalance w . If possible, let another weight v' , produce this effect when applied at K ; and upwards, by means of the pulleys H and G , apply pressures equal to w and v' , the old weights v and w remaining as before. Then there are two systems which

being separately in equilibrium are so when existing in connection. But the under and upper w balance each other; remove them, and there remain two unequal pressures, v and v' , which acting in opposite directions at the same point K , balance each other: a manifest absurdity. Consequently, no other weight except v can balance w when placed at K .

The most simple way in which the preceding result can be stated is as follows: when v placed at K balances w placed at L , about the

K A L

pivot A , the number of *pounds* in v multiplied by the number of *feet* in KA gives the same product as the number of pounds in w multiplied by the number of feet in AL ; (any other units of weight and length will do equally well, if only the same be used in both). The product of a pressure and the perpendicular let fall upon its direction from a fixed pivot or fulcrum is sometimes called the *moment*, sometimes the *leverage*, of the weight.

As the pressure on the pivot A is the sum of the weights v and w , if the lever were suspended at A , by a string passing over a pulley, a counterpoise might be applied in the shape of a weight equal to the sum of the weights v and w . But when a system is at rest, the equilibrium is not disturbed by making any point an immoveable pivot, and taking away any weight which may be there, leaving its place to be supplied by the re-action of the pivot. If then we were to make K a pivot, weights equal to w and $v + w$, acting downwards and upwards at L and A , would counterbalance one another, and since $v \times KA = w \times LA$, add $w \times KA$ to both sides, and we have $(v + w) \times KA = w \times KL$.

In English treatises on mechanics, it is customary to call one of the pressures which balance on a lever, the *power*, and the other the *weight*. Levers are thus distinguished as of the first, second, or third kind, according as the fulcrum, the weight, or the power, is in the middle.

LEVITICUS, is the third book of the Pentateuch, and is so called from *Λευιτικον*, the title given to the book in the Septuagint translation. In Hebrew it is denominated *וַיְקַרְא*, *va yekra*, "and he is called,"

its first word. Both titles indicate the contents, as the book treats principally of the rites, ceremonies, sacrifices, and services, of the Hebrew religion, of which the charge was committed specially to the descendants of Aaron, who, as well as the other Levites, whose duties are more particularly detailed in the book of Numbers, were of the tribe of Levi.

That the book was written by Moses is proved, not only by the Jewish traditions, but by the intrinsic evidence afforded by passages in the book itself, and by others in the Old and New Testaments, in which he is mentioned as the inspired author. In Matthew viii. 4, Jesus himself appeals to the law that "Moses commanded." Some of the German Rationalistic writers have unsuccessfully attempted to prove that the laws originated long after the time of Moses; a conclusion manifestly incorrect, as they have a special relation to the Exodic period, having constant reference to life in a camp, and that camp under the command of Moses.

Leviticus contains little historical information: the deaths of Nadab and Abihu being the only event, besides the consecration of Aaron and his sons to the offices of the priesthood; and the time occupied is by some confined to the eight days employed in this ceremony, while others extend it to a month, and fix the month as the first of the second year after the departure from Egypt. As there are no chronological data given in the book the fact cannot be certainly fixed. The book is closely connected with that of Exodus, which concludes with a description of the sanctuary and the external holiness, while this commences by describing the worship itself. It further develops the legislation as propounded from Sinai, the beginnings of which are given in Exodus; exhibits the historical progress of that legislation; and contains the chief laws relating to the offerings, the feasts, the priests, and the definition of clean and unclean articles of food, not exactly in a systematic form, but in a certain order arising from the nature of the subject, of which the plan may be easily seen.

The book has doubtless also a prophetic character. The sacrifices and oblations which were to procure forgiveness of sins, have reference to the atonement to be made by Christ; as is shown by the whole Epistle to the Hebrews. "The whole service" [of the priests], says Bishop Marsh, "like the veil of Moses, concealed a spiritual radiance under an outward covering; and the internal import bearing a precise and indisputable reference to future circumstances and events, is stamped with the indelible proof of Divine contrivance."

Leviticus is almost uniformly treated of by writers and commentators in connection with the other books of the Pentateuch; but Jahn's *Einleitung*; Hengstenberg's *Authentie des Pentateuches*; Havernick's *Handbuch der Historisch-Kritischen Einleitung in das Alte Testament*, 1839; Knobel's *Handbuch zum Alten Testament*, vol. xii., *die Bücher Exodus und Leviticus*, 1858; Glaire's *Introduction historique et critique aux Livres de l'Ancien et du Nouveau Testament*, 1839, and Horne's *Introduction*, may be usefully consulted.

LEX. [LAW.]

LEX MERCATORIA, or LAW-MERCHANT, in a general sense,

denotes that body of the usages and customs of merchants which has been adopted into the laws of most countries, and particularly of maritime states, for the protection and encouragement of trade. In this view it has been often termed a branch of the Law of Nations. In this general sense the law-merchant is at the present day extremely uncertain and indefinite, as different countries have adopted different portions of it, and the mercantile usages and customs common to all are few in number. Some centuries ago, however, when the transactions of commerce were less complicated, and the rules by which they were governed were consequently simple, the provisions of the Lex Mercatoria appear to have been better understood and ascertained. Thus we find the law-merchant frequently referred to in general terms by our earlier English statutes and charters as a well-known system, and distinguished from the ordinary law; as, for instance, in the stat. 27 Edw. III., 1353, it is declared "that all merchants coming to the Staple shall be ordered according to the law-merchant, and not according to the common law of the land;" and the Charta Mercatoria, 31 Edw. I., 1303, directs the king's bailiffs, ministers, &c., "to do speedy justice to merchants *secundum legem Mercatoriam*."

Lord Coke mentions the law-merchant as one of the great divisions of which the law of England is composed ('Co. Litt.' 11, b.), and the custom of merchants is said to be part of the law of England of which the courts are to take judicial notice. (Vanheath v. Turner, Winch's 'Reports,' p. 24.) This, however, must be understood to apply only to general customs, as the rule does not comprehend particular or local usages which do not form part of any general system. The generality of the expression has caused much misunderstanding, and merchants in this country have been often led to conceive from it, that when practices or rules of trade have become established amongst them so as to amount to "customs" in the common meaning of the term, they form part of the law of the land. This misconception has frequently led to improper verdicts of juries in mercantile trials. It is quite clear, however, that the Lex Mercatoria, when used with reference to English law, like the Lex et Consuetudo Parliamenti, merely describes a general head or division of the system. What customs or rules are comprehended under that division must always be matter of law for the consideration of the judges; and it is said by Chief Justice Hobart (in Vanheath v. Turner), that if they doubt about it, they may "send for the merchants to know their custom, as they may send for the civilians to know their law." In modern times the courts would inform themselves by directing an issue; and indeed it is chiefly in trying disputed questions before a jury that evidence of mercantile customs is given. As to what is understood by the law-merchant in England, and whence it is derived, see the Introduction to Smith's 'Mercantile Laws.'

LEXICON. [DICTIONARY.]

LEYDEN JAR. [ELECTRICITY, COMMON.]

LIBATION, an essential part of sacrifice among the Greeks and Romans. It consisted in the offering up of any liquid to the gods, usually of wine, water, or milk. Libations were also made at funerals, and on various occasions of public and private life when an appeal was made to the gods—as at solemn prayers, before drinking at meals or festivals, &c. (Pitisci 'Lexicon Antiq. Roman.' tom. ii., pp. 74, 75; Gyrard., 'Syntag. Deorum,' l. xvii.)

LIBAVIUS FUMING LIQUORS. [TIN, Bichloride of.]

LIBEL is a malicious defamation, expressed either in writing, or by signs, pictures, &c., tending either to blacken the memory of one who is dead, or the reputation of one who is alive, and thereby exposing him to public hatred, contempt, or ridicule. (Hawk. 'P. C.')

This species of defamation is termed *written scandal*, and from the considerations that the offence is committed upon greater deliberation than the mere utterance of words, which are frequently employed hastily and without thought, and that the effect of a writing continues longer and is propagated farther and wider than verbal defamation, it is generally treated as a more serious mode of defamation than slander. [DEFAMATION; SLANDER.]

Whatever written words tend to render a man ridiculous or to lower him in the estimation of the world, amount to a libel; although the very same expressions, if spoken, would not have been slander or defamation in the legal sense of those words. [SLANDER.] To complete the offence, publication is necessary, that is, the communication of the libel to some person. The mere writing of defamatory matter without publication is not an offence punishable by law; but if a libel in a man's handwriting is found, the proof is thrown upon him to show that he did not also publish it.

There are two modes in which libellers may be punished, by indictment and by action.

The former mode is for the public offence, for every libel has a tendency to a breach of the peace by provoking the person libelled; the latter, by civil action on the case, to recover damages by the party for the injury caused to him by the libel.

On the criminal prosecution it is, at common law, wholly immaterial whether the libel be true or false, inasmuch as it equally tends to a breach of the peace, and the provocation, not the falsehood, is the thing to be punished; and therefore the defendant on an indictment for publishing a libel was not allowed to allege the truth of it by way of justification. But in a civil action the libel must appear to be false as well as scandalous, for the defendant may justify the truth of the facts, and show that the plaintiff has received no injury at all.

But although the truth of a libel is no justification in a criminal prosecution, except when pleaded under the recent statute, 6 & 7 Vict. c. 90, hereafter mentioned, yet it is so far considered an extenuation of the offence, that the Court of Queen's Bench will not grant a criminal information unless the prosecutor by affidavit distinctly and clearly denies the truth of the matters imputed to him, except in those cases where the prosecutor resides abroad, or where the imputations are so general and indefinite that they cannot be expressly contradicted, or where the libel is a charge against the prosecutor for language held by him in parliament. And it has been said that a grand jury should be governed by the like rule in finding an indictment for the offence.

A fair report of judicial proceedings does not amount to a libel, but a publication of ex-parte proceedings before a magistrate may be punished as such.

A petition, containing scandalous matter, presented to parliament or to a committee of either house, and legal proceedings of any kind, however scandalous the words used may be, do not amount to a libel. But if the petition were delivered to any one not being a member of parliament, or the legal proceedings were commenced in a court not having jurisdiction of the cause, they would not be privileged. Confidential communication reasonably called for by the occasion, as charges made by a master in giving the character of his servant to a party inquiring after it, or a warning by a person to another with whom he is connected in business as to the credit or character of a third party about to deal with him, are considered as privileged communications, and are not deemed to be libels unless malice be proved, or the circumstances be such that malice may be inferred by the jury.

After some controversy, it was settled that the jury, in a criminal prosecution for libel, must find not only the fact of publishing, but whether the matter in question be a libel or not (32 Geo. III., c. 60); but in a civil action the question whether the publication is or is not a libel is decided by the judge or court.

The punishment in a criminal prosecution may be fine and imprisonment; and upon a second conviction for publishing a blasphemous and seditious libel, the court may sentence the offender to banishment for any term it may think fit. (1 Geo. IV. c. 8.)

The law of libel had been frequently complained of, and with some appearance of reason, particularly that part of it which prevented the defendant from giving evidence of the truth of the libel in justification when subjected to a criminal prosecution. Almost the only reason, if reason it can be called, alleged in favour of the old law, the one already alluded to, that the libel, whether true or false, equally tends to a breach of the peace; or, as it has been somewhat whimsically said, the being true makes the libel more likely to produce a breach of the peace. Lord Mansfield, indeed, from the bench has said, "the greater the truth, the greater the libel." After much discussion had taken place upon this subject, the statute 6 & 7 Vict., c. 96, was passed, which enables the defendant, in pleading to an indictment for a libel, to allege the truth of the matters charged, and that it was for the public benefit that they should be published. The truth of the libel may then be inquired into at the trial, but does not amount to a defence unless the publication was for the public benefit. If, after such a plea, the defendant is convicted, the court may, in pronouncing sentence, consider whether the guilt of the defendant is aggravated or mitigated by the plea.

By the same statute, a defendant is now enabled in an action for slander, or for libel (giving notice in writing to the plaintiff at the time of pleading, of his intention), to give in evidence, in mitigation of damages, that he made or offered an apology before action, or as soon afterwards as he had an opportunity, in case the action was commenced before. And in an action for a libel in a newspaper, or other periodical publication, the defendant may plead that it was inserted without malice, and without negligence, and that before action, or at the earliest opportunity afterwards, he inserted a full apology for it; or if the newspaper, &c., be ordinarily published at intervals exceeding one week, had offered to publish the apology in any newspaper, &c., to be selected by the plaintiff. Upon pleading such a plea, the defendant may pay into court a sum of money by way of amends for the injury sustained by the publication of the libel. (8 & 9 Vict. c. 75.)

The printer of a libel is liable to prosecution as well as the writer, and so is the person who sells it, even though ignorant of its contents.

By the 6 & 7 Wm. IV., c. 76, s. 19, a bill of discovery may be supported against the editor of a newspaper or other person concerned in the publication or interested in the property thereof, to compel a disclosure of the name of the author of the libel, or of the name of any person connected with the publication against whom the party libelled may think proper to bring an action.

(Bl. Com.; Starkie and Holt, *On Libel*; Selw., *N. P.*; Bac. Abr., tit. 'Libel'.)

LIBEL, in Ecclesiastical Law. [ECCLESIASTICAL COURTS.]

LIBER REGIS, another term for the 'Valor Ecclesiasticus' of Henry VIII. By 23 Henry VIII., the payment of annates, with all sums paid for palls, bulls, and the like, at the consecration of every new prelate, was restrained. This was followed by 26 Henry VIII., for the payment not only of "first-fruits of all dignities, benefices, and promotions spiritual," but also of an "annual pension of the tenth part of all the possessions of the Church, spiritual and temporal, to the king and his heirs," as supreme heads of the Church of England. The

'Valor Ecclesiasticus' is the return which the commissioners under this Act made into the exchequer. This record, in full, except certain portions which have been lost, was published by the commissioners upon the records of the realm, in 6 vols. fol., 1810-1834. An abridgment of it is preserved in the Office of First-Fruits, entitled 'Liber Valorum,' and was the foundation of the Liber Regis, vel Thesaurus Rerum Ecclesiasticarum, by John Bacon, Esq., receiver of the first-fruits, with an appendix, &c., 4to, Lond., 1786. This latter work also contains an account of such benefices as have been since discharged from any payment to the above revenues, on account of the smallness of their income. See further, on Queen Anne's Bounty, in article BENEFICE.

LIBERTINUS. In the Roman polity persons were divided, with respect to status or condition, into freemen (liberi) or slaves (servi). Freemen were again divided into persons who were born in a state of freedom (ingenui), and persons who had been manumitted (libertini). ('Gaius' i., 10, &c.; and compare Horace, 'Serm.' i. 6, v. 6, 21.) A manumitted slave was called "libertus," that is, "liberatus," "freed," with reference to the act of manumission, and to his master, who, by manumitting him, became his patron (patronus): he was called "libertinus" with reference to the class, to which, by the act of manumission, he belonged. It is sometimes said in modern works that the "libertinus" was the son of the "libertus;" and such, according to Suetonius, was the meaning of the term "libertinus" in the time of the censor Appius Claudius, and for some time after ('Claud.' c. 24); but the term "libertinus" in aftertimes was used in the way here stated.

A manumitted slave might either become a full Roman citizen or a Latinus [LATINUM JUS], or he might obtain no higher privileges than belonged to the class called Dediticii. The grounds and conditions of this triple distinction are fully explained by 'Gaius' (i., 12, &c.) The three modes of manumission, by any one of which the freedman might obtain the rights of a Roman citizen, were the "vindicta," "census," and "testamentum." The practice of manumitting slaves having become very common, and being productive of great inconvenience, various provisions in restriction of the power were imposed by the Lex Aelia Sentia, passed in the time of Augustus. By this law, if a person manumitted a slave for the purpose of defrauding his creditors, or for the purpose of detracting from the rights of his patron, the manumission was void. By the Lex Furia (Fufia) Caninia, also passed in the time of Augustus, before the Lex Aelia Sentia, a man could only manumit by his testament a certain proportion of his slaves. This enactment was repealed by Justinian's Legislation.

Though the sons of "libertini" were ingenui, it appears from numerous passages of the Roman writers that they were not unfrequently exposed to the taunts and sneers of those who could boast a pure descent from free-born ancestors. Horace says of himself, "Quem rodunt omnes libertino patre natum." ('Serm.' i. 6, 46.)

It appears from the definition of Gentilis, as given or sanctioned by the Pontifex Scævola (Cic., 'Topic.' 6), that a "libertinus" could have no Gens; but the doctrine of the Gentilitas (gentilicium jus), which was once of great importance as to the succession to the property of an intestate, had fallen into desuetude in the time of Gaius (iii., 17). Two inscriptions (Nos. 3024, 3029) in Orelli, probably of a late date, commemorate the fact of a freedman marrying his former mistress (patrona).

The relation between a freedman and his patronus is more properly discussed under the head of PATRONUS.

LIBERTUS. [LIBERTINUS.]

LIBERTY. This word is the Latin *libertas*. The corresponding Teutonic word is *freiheit*, or, as it appears in English, *freedom*.

Liberty and freedom are familiar words with indefinite meanings. "Liber," the adjective which corresponds to the noun "*libertas*," is properly opposed to "*servus*," or slave; and *libertas* is the status of a freeman, as opposed to *servitus*, or the status of a slave. This division of freemen (*liberi*) and slaves (*servi*) was the fundamental division of persons in the Roman law (Gaius, i. 9). This word liberty, then, in its origin, indicates merely the personal status of a man as contrasted with the condition of servitude. In Greek the like opposition is expressed by two other words (*δεσπότης*, *δούλος*). But the word *libertas* had also a political meaning among the Romans. When the Romans had ejected their last king, they considered that they had obtained their liberty. (Livy, ii. 1.) The political meaning of *libertas* (liberty) was derived from the contrast of liberty and servitude in the person of individuals; and if the mass of a nation were subjected to the arbitrary rule of one man, that was considered a kind of servitude, and the deliverance from it was called *libertas*, a term which in this sense is clearly derived from the notion of liberty as obtained by him who was once a slave.

In the Greek writers the words (*δεσπότης* and *δούλος*), which respectively signify master and slave, were also applied in a political sense to signify monarch and subject. The Persian king was master (*δεσπότης*) and his subjects were slaves (*δούλοι*).

The political sense then of liberty and freedom, if traced to its source, is founded on the notions of personal liberty as contrasted with personal servitude. He who became free from being a slave in a republic became a member of the state, in which he formerly had no political existence. It is implied by the circumstance of his becoming

free that he became a citizen, though positive law, as among the Romans, might limit the degree in which he thereby obtained citizenship. [CITIZEN.] Slavery may and did exist in many states of antiquity which were under monarchical or tyrannical rule; but he who was the slave of an individual in any such state, and obtained his freedom, did not thereby become a citizen, but was merely released from the duty that he owed to his master: he still owed together with others the duty of perfect obedience to an individual monarch or tyrant.

The words liberty and freedom, as political terms, have always been used to express a condition of a people in which they are to some degree at least secured against the arbitrary rule of an individual or of a small number of persons; and the word slavery, in its political sense, is applied to nations in which the mass of the people have not reasonable security for their lives and property against the capricious rule of one man or of a number of persons who form a small minority of the whole.

That which is really meant by political freedom and liberty is nothing more than a form of government which shall in some degree at least secure to the people the enjoyment of life and of their property against the tyranny of one man or of a few. Freedom and liberty then are terms which can only be applied to constitutional governments [CONSTITUTION], and to republics, in the proper sense of that term. There is no political liberty or freedom under any other form of government, though under a monarchy, when the administration is good, there may be in many respects more personal freedom than there is in a pure democracy. But the essential quality by which political liberty or freedom is distinguished is simply this: the sovereign power is not in the hands of one or of a small minority, but it is either distributed among the whole community or a considerable part of it.

Political liberty does not exist in some civilised nations in Europe: in France, for instance. Political liberty does not exist in Russia. In some countries where it does not exist, it is the general opinion that its existence would be a benefit to the whole nation. In other countries the mass of the people are still in such a condition that political liberty could not exist, for political liberty, as already stated, means that the sovereign power must be in the hands of a large number, and they must possess intelligence enough to enable them to exercise and keep the power; but there are nations where the mass of the people are too ignorant to exercise or keep any political power.

A nation which strives for its liberty strives for a popular form of government, whether it be a constitutional kingly form or a democracy. But liberty is a specious word, often ill understood; and many who have cried out for liberty have either not considered exactly what it is they want, or they have supposed that liberty would free them from many evils which they consider to be peculiar to a state of political slavery. It is now generally admitted, that in those states where a large part of the population have equal political knowledge with the few who direct administration, the general interests are best served by this large number participating in the government. Political liberty, then, to some extent or degree, is, in many countries, necessary for securing the advantages of good administration. But there are many evils incident to states, which are not due to the want of political liberty; and it is therefore a matter of importance for those who would make changes in government to consider whether the evils of which they complain are owing to a want of political liberty or to other causes.

The notion of political liberty has been based upon the analogy already pointed out between Political Liberty and Personal Liberty; which is a false analogy, though an historical one. Man, it has been assumed, is naturally free. No man is naturally or by nature another man's slave. As no man, it is said, is naturally a slave, so all mankind have naturally a right to political liberty, and just government, it is said, arises from the consent of the governed.

On these assumptions rests the American Declaration of Independence: "We hold these truths to be self-evident: that all men are created equal; that they are endowed by their Creator with certain inalienable rights; that among these are life, liberty, and the pursuit of happiness; that to secure these rights governments are instituted among men, deriving their joint powers from the consent of the governed," &c.

In this passage Liberty seems to mean the personal status, which is opposed to slavery; and it is on the assumption of the equality by birth and the endowment of all men with certain inalienable rights, that this instrument would found the American title to Political Liberty. It involves the doctrine of the social contract, and assumes, as an historical fact, an origin of governments by consent of the governed. It was also promulgated in a country in which a very large number of persons were then slaves, and in which a large number still are slaves.

If theories of government are to be tested by historical facts, it would be consistent with such facts to say, that men are not created equal; that they have not been endowed with liberty, for a large part of them have always been slaves; and that governments have been constituted without the consent of the governed. These are real facts: those assumptions are untruths.

Political liberty rests on no such sorry basis as the Declaration of

Independence places it on. That nation which can obtain it and maintain it is in a better condition than if it were politically a slave even to the wisest of masters; and when it is able to obtain and maintain that liberty, it is right, or in other words it is for the general interest, that a nation should, by force if necessary, alter that form of government which is political slavery.

That liberty promises to be most stable which is the growth of long time and the result of a perpetual struggle between a master and his slaves, in which the master has not ceased to be master all at once, but has always lost something in the contest.

That which is of sudden growth or is the offspring of Revolution, is often premature, and always insecure; for liberty so acquired may only be a step from a state of political slavery to a more wretched state; it may be a step from a state of slavery, mild and tolerable, to an anarchy, which of all things is most intolerable.

The words Liberty and Equality often go together, and each of them in so doubtful a sense that one hardly knows what to make of them. Liberty is often used, apparently without people considering what they really mean, in the sense of freedom from restraint. But this kind of Liberty is inconsistent with Political Liberty properly understood; and all men's liberty of action is and must be restrained by positive laws in every well-ordered community. Every law that forbids any act directly or by implication abridges Liberty, and such abridgement is always a universal benefit when the law which so abridges liberty only abridges it in cases where it is useful to all that it should be abridged, and where the law is so framed as to accomplish that object. Equality, in its unlimited sense, can no more exist in any state than perfect individual liberty; for if each man is left to exercise his industry in the best way that he can, without interfering directly with the industry of others, some will be richer, and happier, and wiser than others. The only Equality that can be approached to in a well-ordered state is that Equality which is the result of a good polity, which polity, so far as it is consistent with the universal good, secures alike to every individual in the State the free enjoyment of his industry, wealth, and talents, imposes restraint on all alike, and makes all alike bear the burden of taxation and of the services due to the State. Further, it gives to as large a number as it can, consistently with the universal interest, an equal share in the sovereign power; but no polity that has ever yet been framed has ever given an equal share in the sovereign power to all the members of a community: such an Equality is impossible.

The Declaration of Rights published by the French National Assembly in 1791 contains the words "free," "equal," "rights," "liberty," and many others, all used in a manner as remote from precision as the most confused understanding could suggest. This strange sample of nonsense has been examined and dissected by Bentham in his 'Anarchical Fallacies.'

The word Liberties is often used to express those particular constitutional principles or fundamental laws by which the political liberty of a nation is secured. If the British parliament should attempt to abolish the Trial by Jury in all cases, or the Habeas Corpus, such an attempt would be called an attack on the liberties of Englishmen.

Liberty is also used in reference to the religious institutions of a state. Liberty of conscience properly implies that neither is coercion exercised upon, nor inducements offered to, nor disabilities imposed upon, the form of faith of any of the members of the state; but generally in effect it is much more restricted, and the unimpeded exercise of the peculiar form of worship is all that is understood.

LIBERTY. The general nature of a liberty, as a portion of the royal prerogative in the hands of a subject, has been already described. [FRANCHISE.] Liberties were at first chiefly granted to monastic and other religious establishments, in ease of the consciences of the royal grantors, or in testimony of their devotion to the Church; and most of those now in existence are derived from an ecclesiastical source. They were afterwards granted as means of strengthening municipal corporations.

Though all liberties emanate from the prerogative, a distinction is usually made between such liberties as have been actually exercised by the crown before the grant to the subject, and such as (being merely latent in the crown) are said to be created *de novo* upon their being granted. The former, when by escheat, forfeiture, or otherwise, they come again to the crown, are extinguished by merging in the general prerogative, and cannot afterwards be regranted as existing franchises: the latter still have continuance for the benefit of the crown or of any subsequent grantee. To the former class belong such privileges as the right to have the goods of felons, &c., waifs, estrays, and wreck, arising within the lands of the grantee; to the latter, the return of writs, the right of holding fairs and markets and taking the tolls, the right of holding a hundred-court or a court-leet, the privileges of having a free-warren [WARREN; PARK], and the like; and in such cases the franchises, even whilst in the king's hands, are exempt from the jurisdiction of the ordinary officers of the crown, and are administered by bailiffs or other special officers, as when in the hands of a subject.

The fines paid to the crown for grants or confirmations of liberties are shown by Madox to have formed no inconsiderable part of the royal revenue. In his 'History of the Exchequer,' he quotes the particulars of about 200 liberties, granted principally by King John. The following may serve as a specimen of the terms upon which the parties

finer or made agreement with the crown. The men of Cornwall fine in 2000 marks and 200 marks for 20 palfreys estimated at 10 marks each, for a charter for disafforesting the county and choosing their own sheriffs. The men of Brough fine in 20 marks and 5 marks for a palfrey, for a market on Sunday, and a fair for two days. The men of Launceston fine in 5 marks for changing their market from Sunday to Thursday. Henry de la Pommeraiie fines in 5 marks "that the men of Lidford may not have a better liberty than the men of Exeter." Alanus de Munbi fines in 100 marks and 3 good palfreys for a charter of exemption from suit at county courts and hundred-courts for his life. Thomas of York, son of Olivet, fines in one huntsman (*unum fugatorem*) that he may be alderman in the merchant's guild at York. Agnes, the widow of Walter Clifford, fines in one good palfrey to have her manor of Witham in Kent, and that the men of the said manor, being her men, be acquitted of shires, and hundreds, and suits to the county courts and aids of sheriffs and bailiffs, and for the king's letters-patent thereof. The burgesses of Shrewsbury fine in 20 marks and one palfrey that no one shall buy within the borough new skins or undressed cloth, unless he be *in lot* (in *lotto*), and assessed and taxed with the burgesses. [SCOT AND LOT.]

Many of these franchises having been found to interfere with the regular and speedy administration of justice, the extension of them by fresh grants was frequently the subject of very loud complaints on the part of the Commons in parliament, who represented them as prejudicial to the crown, an impediment to justice, and a damage to the people. It appears by the Parliament Roll, that Edward I., towards the close of his reign (in 1306), declared that after the grant which he had made to the Earl of Lincoln for his life, of the return of writs within two hundreds, he would not grant a similar franchise *as long as he lived* to any except his own children, and directed that the declaration should be written in the Chancery, the Gardrobe, and the Exchequer. And in 1347, Edward III., in answer to a strong remonstrance, promised that such grants should not in future be made without good advice.

The form in which the crown granted views of frank-pledge [LEET] and other franchises may be seen in the charters granted by King Henry VI. to Eton College, and King's College, Cambridge. (5 'Rot. Parl.,' 51, 97.)

A person exercising a franchise to which he has not a legal title may be called upon to show cause by what authority he does so, by a writ of *quo-warranto*, or an information in the nature of a *quo-warranto*. [INFORMATION; QUO-WARRANTO.] And parties disturbed in the lawful exercise of a franchise may recover damages against the disturber in an action.

LIBRA (the Balance). In the older Greek writers the Scorpion occupies two constellations of the ZODIAC, or rather the body of the animal occupies one, and the claws, *chela* (*χηλαί*), another. We say this, because though the *chela* were certainly a part of the Scorpion, yet they are often mentioned (as by Aratus, for instance) by themselves, as if they formed a distinct constellation. The word *chela* had several significations; so that it may have been by simple mistranslation that the Romans (according to Hyginus, Virgil, &c.) gave the name of *Libra* to the part of the heavens in question, and drew back the claws of the Scorpion to make room for the scales.

Libra is surrounded by *Scorpius*, *Ophiuchus*, *Virgo*, *Centaurus*, and *Lupus*. Its star β is the vertex of an isosceles triangle, of which *Arcturus* and *Spica* (α *Virginis*) are at the extremities of the base. Its principal stars are as follows:—

Character.	No. in Catalogue of Flamsteed.	No. in Catalogue of British Association.	Magnitude.
α	9	4895	2
δ	19	4939	4
γ	20	4950	3
β	27	5034	2
ζ	32	5089	4
	39	5138	4
κ	43	5176	4
η	44	5190	4
χ	45	5251	4
θ	46	5257	4
ψ	48	5290	4

LIBRARIES. The word library is used to denote a collection of books, whether large or small, and also the repository in which that collection is placed, whether a few shelves or a room, a house or a palace. The English term is derived from the Latin language, but in Latin itself a library is usually expressed by the word "*bibliotheca*," taken from the Greek. The Greek phrase thus adopted by the Romans has passed from them not only into every language of the Romanic family, but into almost every other cultivated language but our own, for strangely enough, though repeated attempts have been made to naturalise it, it has never taken root in the English vocabulary, which is not usually so fastidious.

Of late years the study of libraries—their formation, arrangement, management, and history—has been raised to the dignity of a science. Schrettinger in German, Molbech in Danish, Constantin Hesse in French, have written respectively on "*Bibliothekwissenschaft*," "*Biblio-*

thekvidenskab," and "*Bibliothéconomie*," a branch of knowledge for which no English term has yet been invented. In spite of the prescription of "*bibliothèque*," some phrase like "*bibliothecology*" will probably ere long find its way into our dictionaries, to keep company with "*ecclesiology*," and other modern innovations. A mode of representing the German phrase in English is likely to be required, as the science itself has found so much favour in German eyes that a periodical was commenced in 1840, which still continues to be published expressly for the purpose of reviewing books that touch upon it. Dr. Petzholdt's '*Anzeiger für Literatur der Bibliothekwissenschaft*.' In addition to the circumstances which have always operated to render great libraries objects of interest to enlightened men, the position of libraries in general has been remarkably altered in the course of the present century, and more especially in the course of the last forty years. The operation of the causes which produce these results is rapidly progressive, and the subject appears likely to increase in interest with every succeeding year.

The existence of a library of some kind must date back nearly as far as the existence of writing. The book which is emphatically called "*the book*"—the Bible—is itself a collection of books of different kinds: poetry, prophecy, and history of different ages, from the time of Moses to the time of Malachi. In Greek its name is not the '*Bible*,' but the '*Bibles*'; and in the middle ages it was often called '*the Library*,' '*the Bibliotheca*.' It probably constituted among the early Hebrews the whole library of the Synagogue. Its first translation, the Septuagint, was expressly written to enrich a larger library—the great collection of books which, founded by Greeks on the soil of Egypt, was destined to become the greatest and most famous collection of all antiquity. The book which was first introduced to the Alexandrian library of the successors of Alexander the Great, as an exotic curiosity, became in the course of centuries the book of the religion of Egypt—till, as we shall see, that noble library finally perished after its varied fortunes of nine hundred years, by command of the Mohammedan caliph, who condemned all books as useless or injurious but the Koran. That library must then have embraced thousands of volumes which were a comment on that early translation for which the world was indebted to its founders. At this moment the royal library of Stuttgart contains 8700 editions of the Bible, and that of the British and Foreign Bible Society in London, is almost entirely a collection, and a very imperfect one, of the translations and comments on that single volume.

As one book thus becomes connected with, and even essential to, the understanding of another, so whole libraries of books stand in the same relation. The library just mentioned, that of the British and Foreign Bible Society, contains, as we learn from Mr. George Bullen's valuable catalogue, translations of the Scriptures into upwards of 150 languages, many of them languages in which no other book exists. The library is thus of essential importance, not only to the biblical but to the philological student. At the same time the investigator into languages is unable to make full use of the treasures it contains unless he has also access to a large collection of grammars and dictionaries, a library of entirely a different description. It is evident that if a biblical and a philological library existed in different parts of the same city, unconnected with each other, a great service would be rendered to the frequenters of both by bringing them under the same roof, and rendering them accessible at the same times. The collections might remain precisely the same, the expenses of management might by the blending of the two into one be easily reduced, but the advantages would be great, and they would be mutual. The biblical student and the missionary might make use of the dictionaries to study the Hebrew and Arabic and Tahitian Bibles, the philological student might make use of the Bibles to study the Hebrew and Arabic and Tahitian languages.

The benefit to be drawn from the amalgamation of libraries, so far from decreasing, seems to increase, the farther that amalgamation is carried. It is both theoretically and practically impossible to draw any strict limitation to the bounds of any extensive study. To pursue the instance of the Biblical student, how many sciences fall within his range. The ecclesiastical law is founded on the Scriptures, and in every church and country there are different forms of ecclesiastical law. The history of the Church is inextricably connected with the history of every Christian state. The geography of the Holy Land has been for ages a theme of research, and the natural history of the Scriptures another. Church architecture is one of the most prominent forms of the art, painting has had its highest triumphs in scriptural subjects. On all these sciences, arts, and studies, whole libraries have been written, and there is hardly a book of those libraries which the student of any of those subjects may not have occasion to consult. If a missionary, the field of his inquiry becomes still more widely extended. A missionary to Mohammedan countries ought to be acquainted with the Koran, to India with the Vedas, to China with the books of the Buddhists and the works of Confucius and Laou-Tsze. The historian of Christian missions, the historian of religion in general, should have some knowledge of all the creeds of the heathen.

It would seem to follow from these considerations that the union of whole libraries is as essential for the purposes of study as the bringing together of single books, and that it should be an object with all who wish to cultivate the progress of knowledge, to favour the

formation of at least one library of the largest possible extent, to contain all printed books of value.

This view may be supported by the authority of one who, when his passions were not concerned, was perhaps the most clear-sighted man of genius who ever dealt with practical subjects. In the report presented in 1860 to the Emperor of the French on the state of the imperial library at Paris, reference is made to the opinion expressed by his uncle, the first Napoleon, in a note dictated on the 10th of February, 1805—"many ancient and modern works are wanting in the great library," said Napoleon, "which are found in the other libraries of Paris, and of the departments. A list should be made of these books, and they should be taken from the minor establishments, to which should be given in exchange works which they do not possess of which the great library has duplicates. The result of this operation would be, that when a book was not found in the imperial library it would be known for certain that it did not exist in France."

The notion of a central and universal library of this kind has the advantage of being, not only philosophical, but popular. It has been a prevalent belief in several countries that this ideal library actually existed. The Vatican at Rome was long supposed to be such a collection, and to contain an enormous quantity of volumes. The Rev. Mr. Eustace, an English Catholic priest, who published a 'Classical Tour in Italy,' in 1813, said, in speaking of the printed books of the Vatican library, "Their number has never been accurately stated; some confine it to 200,000, others raise it to 400,000, and many swell it to a million—the mean is probably the most accurate." The most recent historian of the collection, Zanelli, in 1857, speaks of it as "holding the first place among the libraries of the world, both by its antiquity and the value and number of its volumes and manuscripts." At Oxford, in the early part of the present century, it was almost an article of faith with the under-graduates that the Bodleian library was only second to the Vatican, and further, that it contained every printed book. The number of volumes in it was usually stated to visitors at half a million: a German statistician, Schnabel, on the faith of the assertion in the 'Oxford Guide' of its near approach to the Vatican, raised the number in print to 700,000. The same notion of its containing every printed book was current in London at the same time respecting the British Museum. In all three cases the belief was a most egregious error.

Two German writers of reputation, Denis, in 1775, in his 'Introduction to Bibliography,' and Blume, in 1824, in his 'Iter Italicum' reduce the number of printed volumes in the Vatican to 30,000. Valéry the Frenchman, in 1826, speaks of it as 80,000. The marquis Melchiori in his 'Guida Metodica,' printed at Rome in 1836, gives the number at 100,000; and as Zanelli twenty-one years after does not venture to correct him and gives no number at all, it may be assumed that Melchiori was near the mark. An official return of the Bodleian librarians to the House of Commons in 1849 stated the number of their volumes then, after all the increase of half a century, at 220,000 only; and the British Museum in 1820, contained less than 116,000, while though it has now in 1860, attained to more than five times that number, and more than doubles the Bodleian, it is still far indeed from a state of even tolerable completeness.

It is remarkable at how recent a date the period of really extensive libraries commenced. Adriano Balbi, the Italian statistician, who in his ingenious essay on the library of Vienna, published in 1835, furnished a large body of information on the subject critically sifted, gives an estimate of the number of books in several of the great libraries of Europe in 1789, at the commencement of the French Revolution. The Imperial Library at Vienna was then in his judgment the largest collection in Europe, and contained 196,000 volumes. Three other libraries in Germany stand nearest to it in his estimate. To the royal library at Dresden he assigns 190,000; to the royal library at Berlin 160,000; to the university library at Göttingen also 160,000 volumes. To the Zaluski library at Warsaw he gives 150,000; to the royal library at Paris 149,000, only. The only English library he mentions is the Bodleian, to which he assigns 135,000 volumes in 1789.

At the time to which Balbi refers,—the outbreak of the French Revolution,—the library of the king of France in Paris was currently believed by some to amount to three hundred thousand, by others to five hundred thousand volumes, and was considered by Frenchmen and competent judges the noblest collection in Europe. The authority on which Balbi assigns it so low a number as 149,000, is that of actual counting—the fatal test, the application of which has suddenly shrunk the dimensions of so many far-famed libraries. Van Praet the librarian, who himself accomplished the operation, tells us in the preface to his 'Catalogue des livres imprimés sur velin,' published in 1822, that "counted one by one in 1791, the number of volumes only amounted to 152,868; namely, 23,243 in folio, 41,373 in 4to., and 88,252 in 8vo. and of lesser sizes."

Guided by this positive information, Balbi is of course perfectly justified in giving the number he states. But he seems not to have been aware that the Zaluski library, which he only places immediately above it, was counted also, and with a result which is startling. Seized by the Russians in 1795 and transported to St. Petersburg, where it now forms the basis of the Imperial library, the volumes were counted on their arrival, and were officially stated to amount to the enormous number of 262,640. The enumeration which was sup-

plied by the Russian government, and is given with various particulars in the Report of a Committee of the House of Commons on the Museum library in 1836, is not very clear in some respects, for in one portion of it, 43,000 pamphlets are inserted as so many volumes, and in another, 120,000 pamphlets which are mentioned are not added into the total sum. But estimating these 163,000 pamphlets as 16,300 volumes, of ten to a volume, according to a convenient rule adopted by Balbi, the number of volumes transported to St. Petersburg will be in round numbers upwards of 235,000. It should not be forgotten that there is undeniable evidence that the library had been seriously pillaged while still at Warsaw. If this number be correct, and it is as well vouched for as the census of most libraries, it will not only follow that the collection of books made in his lifetime by one Polish bishop with the assistance of another, was the largest collection ever made at private expense, but that it actually surpassed in numbers the magnificent library of the kings of France, and was at the head in that point of all the collections in Europe, some of which had been gathering together for centuries at the expense of nations.

In the wars which followed the French revolution, many a revolution took place in the affairs of libraries. The royal library of France was augmented enormously both in extent and value by the absorption of the libraries of the suppressed religious houses, and the contributions levied on conquered foreign states. The latter treasures were restored at the restoration of peace, but the French library remained in 1815 what it still continues, the largest and most celebrated library in Europe. Van Praet in 1822 spoke of it as having increased two-thirds from the time when he counted it in 1791, and as containing 450,000 volumes, not including as many pamphlets and pieces bound in volumes or kept in portfolios, and it was then augmenting at the rate of 7000 volumes a year, and 3000 fugitive pieces. In the year 1850 the number of volumes in the library, according to an official return procured by the British ambassador, was 750,000, of which 50,000 were volumes of tracts or pamphlets containing about ten tracts each, and therefore in all 500,000. In 1855, in the preface to the new classed catalogue now in course of publication, it was stated that the collection comprised 1,500,000 volumes and pamphlets, without drawing a distinction between the two.

If we adopt Van Praet's estimate of the number of volumes and tracts being equal, there will then be 735,000 volumes and 735,000 tracts; and counting the tracts according to Balbi's method at ten to a volume, the number of volumes in 1855 will be 808,500, to which if we add augmentations at the rate of 11,000 volumes a year, the total will in 1860 be 863,000.

The Zaluski library, removed to St. Petersburg, was for some time left there in a state of such neglect that, when again counted in 1803, it was found to have diminished by decay and theft to 238,633 volumes—a number still remarkably high. It was again injured by its sudden removal, on Napoleon's invasion of Russia, from St. Petersburg to a remote village, to keep it out of the way of the invaders, who, in this case, as there were Poles among them, would only have been recovering their own property. In 1833 and 1834 it was augmented, as we learn from the Official Guide to the library, by more than 125,000 volumes, procured by the Emperor Nicolas from the spoils of several Polish magnates and public institutions, in particular from those of Prince Czartoryski's country seat at Pulawy and the library of the society called the "Friends of Knowledge" (the Polish Royal Society) at Warsaw. Finally, the more ordinary and creditable mode of augmenting the library by purchases and donations came into operation; and in the Official Guide for 1850 we are told that the library then contained upwards of 600,000 volumes of printed books, together with collections of manuscripts, engravings, &c. In the annual report of the librarian for 1858, the last we have seen, the number of printed volumes, pamphlets, and pieces added in that year is given as 38,136; and in the same year the officials of the library issued a detailed comparison of its state in 1850 and 1858, from which the following items are taken.

	In 1850.	In 1858.
Of printed books, volumes	640,000	802,717
Of manuscripts and collections of auto- graphs, volumes	21,415	28,536
Of engravings, pieces	39,815	63,503

In the 'Guide to the Imperial Public Library of St. Petersburg,' published in 1860, the numbers given are 840,853 printed volumes, 29,045 manuscripts, and 66,162 engravings.

It would appear from these numbers that the library of St. Petersburg is now the second library of the world, and increasing with more rapidity than any other. This impression, however, must not be too hastily adopted. There is a collection now publishing by the English Patent Office, of all the descriptions of patents of inventions that have been enrolled there from the institution of patents in the time of James I. up to the present year. This voluminous and costly collection, which is printed at the expense of patentees, is presented by the Patent Office to a great number of foreign libraries, and among others to the imperial library at St. Petersburg. The number of patents for the year 1857 is no less than 3200, published in as many separate pamphlets, which are bound in the set at the British Museum in 96 thickish volumes. In counting the volumes at the

Museum they will be reckoned at 96, while we are told on good authority that at the library at St. Petersburg they are counted as 3200, making a difference in the returns of the same annual set of more than 3100, and in the returns for the whole collection of patents of more than 24,000 volumes.

Another great European library is frequently said to contain more than 800,000 volumes—the collection at Munich, but in that case the statement will not bear the slightest investigation. Dr. Petzholdt, in his excellent '*Handbuch der deutschen Bibliotheken*,' gives the numbers thus, out of which the total is composed—

16,000 Manuscripts
13,000 Early printed Books
250,000 Printed Works
100,000 Dissertations
300,000 Pamphlets

These numbers added together give 679,000 only, but it will be observed that as one of the items is 250,000 *works*, it may be alleged that as there are so many works in two or twenty, or even a hundred volumes, the difference may thus be made up. Two of the other items however are 100,000 dissertations, and 300,000 pamphlets. Taking these at 40,000 volumes altogether, according to Balbi's rule, and deducting the 16,000 manuscripts, the library at Munich is at once reduced to 424,000 volumes.

The third, if not the second, great library in Europe is now that of the British Museum. In a previous article in this Cyclopædia [BRITISH MUSEUM] some of the steps have been pointed out by which it has emerged to importance in the course of the last quarter of a century from a position of inferiority, not only to the libraries of Vienna and Berlin, but to those of Munich and Copenhagen. The number of volumes in the library was officially stated in 1858 at 550,000, and the numbers added since must have carried it over 600,000. These numbers are arrived at by counting the volumes as they come from the hands of the binder, not as they go to him; reckoning a pamphlet bound separately, however insignificant, as one volume, and also reckoning a three-volumed novel as one volume only, provided the three volumes are, as they generally are at the Museum, actually bound in one.

This system of counting is hardly satisfactory, for it makes the numbers vary in cases where the books remain the same. A volume of old pamphlets sent to the binder to be taken to pieces goes one volume and comes back a dozen, while 300 volumes of novels return shrunk to a hundred. If a congress of librarians were ever to take place in Europe, as it did a few years ago in America, one of the first things for them to settle would be the method of counting libraries. If every separate work under 100 pages were to be considered a pamphlet, if ten of such pamphlets were counted as one volume, and if in other cases the divisions made by the printer and not the binder were taken as a guide, a better comparison of the extent of libraries would be practicable, and the British Museum would probably be found to stand still higher than it now appears to do, even in point of numbers. The rank of a library, however, does not entirely depend on its number of volumes, however important an element that may be. The Zaluski library, though in 1789 it outnumbered that of the Kings of France, could not have approached it in point of value. The first book printed in English by Caxton, one of the treasures of the Museum, sold the last time a copy came to auction for over 1000*l.*, while a hundred thousand dissertations, now in the Advocates' Library at Edinburgh, were bought for less than a farthing each. There can be no doubt that in numbers, and also in intrinsic value, the hundred thousand dissertations far surpass the '*Recuyell of the historie of Troye*,' but a library which aims at universality must aim at possessing both.

Under all circumstances, it appears remarkable that this idea of a complete or universal library, so long and so generally current, should never have approached to a more thorough realisation. Of all institutions of public magnificence, that of a great library is at the same time the most useful and the least expensive. A few years ago a single picture by Paul Veronese was bought for the National Gallery for 13,000*l.* The highest sum that has ever been voted by the House of Commons to the British Museum for the purchase of printed books for a whole year is 10,000*l.* There can be little doubt that if 10,000*l.* a-year had been voted uninterruptedly for the purchase of books for the last fifty years, and had been judiciously expended, the nation would now be in possession of the finest and completest library the world has ever seen, and perhaps of a finer and completer than the world will now ever see.

Such a library should, if anywhere, be in London. A great deal depends on the locality in which a library is placed. That of the kings of France was once kept at Blois, and for a long time afterwards at Fontainebleau. It was one of the good deeds of Henry IV. to remove it to Paris, and one of the good deeds of Louis XIV. to leave it there, instead of removing it to Versailles. The great library of England was for two centuries at Oxford, where it was founded amid universal acclamation in close neighbourhood to numerous college libraries, at a time when there was no public library whatever in the capital. Of all places in the world, London would appear to be the most appropriate for the seat of a great permanent

and universal library. Talleyrand is reported to have said that Paris was the capital of Europe, and London the capital of the globe. No other capital stands in such direct and constant communication with all the ends of the earth,—no other has such a vast resident population,—and no other, except Paris, is visited by such an immense variety of strangers. An institution not far from its centre is within easy reach of two millions and a half of persons. Shielded by its sea from the Continent, England has for ages been the asylum of foreign refugees, and is the safest asylum in Europe for persecuted books. It is remarkable that while England is as distinguished for its opposition to centralisation, in many important respects, as France is for its attachment to that form of rule, the two countries exchange their characteristics in the very case in which the advantages of centralisation are the most capable of proof. Paris boasts of several public libraries, of which some are almost rivals of the principal; and a reader who wishes to study a particular language may possibly find the grammar of it in one collection, the dictionary in another, and the chrestomathy in a third. In London, the one great library of the British Museum towers above all rivalry since its important accessions of the last forty years; and while the first library of London has more than 600,000 volumes, the second has hardly one tenth of that number.

Even when a collection aims at universality, there are of course some points to which more importance will be attached than to others. In a national collection the first object should be the national literature. There is an admirable saying related of the Spanish poet, Moratin the elder, that when he was once asked by a young fellow-countryman what authors he should study, he replied, "Spanish and Greek, Spanish and Latin, Spanish and Italian, Spanish and French, Spanish and English." The spirit of the saying should serve as a guide to the librarian who is fortunate enough to have the selection of the purchases for a large national and universal library.

It has been already remarked, that owing to the altered circumstances of recent years some of the opportunities of forming a complete collection of valuable literature which have been allowed to escape, will probably never recur. It is to English literature in particular that this remark applies, and a glance at the history of the principal attempts to embody it in libraries will confirm the view.

At the time that the Bodleian library was founded at Oxford in 1602, there would have been little comparative difficulty in forming a complete collection of the literature of the English language. In the preceding century, during and after the struggles of the Reformation, many English books had been printed abroad, at first by the Reformers, and then after the Reformers' triumph, by the Catholics, but all of them had been intended for the market at home, and circulated here. Almost all the remaining literature of the language was issued at London, and by the members of the Stationers' Company, and the transfer to the Bodleian of the privilege of the Stationers to receive a copy of each book entered at their hall, seemed to ensure that a complete collection of English literature should in future exist. The brilliant prospects of the Bodleian in this respect were destroyed by the remarkable shortsightedness of the founder, Sir Thomas Bodley. "I can see no good reason," he wrote to the first librarian, Dr. James, "to alter my opinion for excluding such books as almanacks, plays, and an infinite number that are daily printed of very unworthy matters and handling, such as methinks both the keeper and under-keeper should disdain to seek out to deliver to any man. Haply some plays may be worth the keeping, but hardly one in forty. For it is not alike in English plays and others of other nations, because they are most esteemed for learning the languages, and many of them compiled by men of great fame for wisdom and learning, which is seldom or never here among us." Nothing can be added to the force of the simple remark that this passage was written by a contemporary of Shakspeare. Of course the opinion of the librarian was obliged to bend to the will of the founder, and it would be difficult to estimate the damage that has been done to literature by this unfortunate decision of that illustrious man. For more than two centuries afterwards, it appears to have been the practice of the Bodleian librarians to sell or destroy such books as they judged unworthy of a place on their shelves, and this unhappy example was followed in other libraries. In Hyde's catalogue of the Bodleian, published in 1674, the only collection of Shakspeare's plays is the folio of 1664; and the only separate play is a '*Hamlet*,' published after the Restoration. Though the dramatist was known to be the favourite of "Eliza and our James," and also of King Charles, who held court at Oxford, neither the first nor the second folio was deemed worthy of a place on the shelves of the University. But when, more than a century afterwards, the tide had so changed that one of the chief glories of the Bodleian was in the Malone library of Shaksperian literature, presented to the University by his brother; and when, in 1841, Marlowe's play of the '*Contention of the Houses of York and Lancaster*,' a single one of the mass rejected by Bodley, was bought by the Bodleian library for 131*l.*, a lesson was read which ought to sink deeply into the minds, not only of the Bodleian, but all other librarians.

A complete contrast to Sir Thomas Bodley was presented by one who was probably his contemporary for a part of his life, George Thomason, a bookseller of St. Paul's churchyard, who at the commencement of the great civil strife in 1640, was struck with the happy idea

of collecting every publication and pamphlet that appeared on both sides in that memorable contest; and with unshaken constancy, and at immense expense and trouble, carried out his project till the Restoration in 1660. His enterprise was less prudent than patriotic, for his hopes appear to have been to dispose of, not to retain the collection, and the Restoration left him but two probable purchasers, in the Bodleian library and the king; though it could hardly be expected that the university would wish to recall the downfall of the church, or the monarch the downfall of the monarchy. The university, however, only declined on the ground of want of funds; and the king actually purchased but would never pay, so that Thomason's representatives, who had at first been glad to be quit of the burden, were glad to receive it back. After the lapse of a century the collection was finally purchased by George III., and presented to the British Museum, where it still remains, a library in itself, often consulted for various purposes, but never as yet thoroughly explored. Thomason was fortunate in the time and country of his enterprise. The contemporary French collectors of 'Mazarinades,' as they were called, or the innumerable pamphlets against Cardinal Mazarin, amassed what was comparatively worthless. He was less fortunate in another respect, for while their collections have found a special historiographer to describe them, Thomason's still awaits one, and his name has never yet received the measure of honour which is its due.

For the remainder of the 17th century and for the earlier half of the 18th, the Bodleian continued the only library of national importance. The taste for private libraries arose and flourished, and one among them was remarkable for containing an immense assemblage of pamphlets, which might well have been made the foundation of a national collection. It may be supposed that the number of 350,000, which has been mentioned as that of the pamphlets, English and foreign, in the Harleian library, was much exaggerated, but there can be no doubt that a great and perhaps irreparable loss to literature was sustained, when that collection was allowed to be dispersed in 1741. Twelve years after, by the fortunate will of Sir Hans Sloane, and the fortunate acceptance of its provisions by the legislature (in case of whose refusal the library and museum were to be offered to St. Petersburg), a great library was at length, after more than one project had proved abortive, founded in London. The presentation to it by George II. of the library of the kings of England at once stamped it as national: but it was not till the presentation of another royal library, seventy years later, that of George III., by George IV., in 1823, that the Museum collection took the first rank among the libraries of England.

The time of the foundation of the Museum was only later by a few years than the time in which any general attention was first attracted abroad to English literature. In Holland indeed, for a full century previous, owing to commercial and political connection of the two countries, our language had been frequently studied, and in Germany and the north, theologians and scholars had occasionally mastered it for their purposes, but it was in Western Europe almost unknown. Garnier, a French Jesuit, who published a method of the arrangement of libraries in 1678, gave no directions respecting English books, because, as he observed, English books seldom crossed the sea. It was not till the memorable visit of Voltaire to England that a knowledge of the language and literature was introduced into France, and the study became so general, that Mr. Buckle in his 'History of Civilisation,' gives a list of more than a hundred and fifty French authors who are recorded to have had a knowledge of English. The English collector however found no competitors in foreign bibliographers for the purchase of rare and curious English books. The few specimens of the press of Caxton, some of them rare and curious, that are to be found on the continent, are in general those which he printed abroad in French, before he introduced the art into England. Of early English bibles, Christopher Anderson reports in his 'Annals,' that he found but a scanty provision in the great library of Paris, and it may be doubted if in all the continent half a dozen specimens exist of a quarto Elizabethan play. If the library of the Museum had then been provided with funds for the purpose, a good opportunity existed for many years of furnishing it with an excellent collection of English literature at a moderate expense. Books did not begin to fetch high prices till the sale of Dr. Askew's library in 1775, and then the general run was on classics or works of foreign literature.

That opportunity was lost, when soon after the commencement of the 19th century, the "bibliomania" awoke in England, and one of its most frequent forms was the craving for early English literature, to be gratified at any cost. During the early years of the century, at the times of the sale by auction of the library of the Duke of Roxburghe, and the foundation of the Roxburghe club, to commemorate the enormous price that was given there for an edition of Boccaccio's 'Decameron,' the competition at public sales was almost entirely between private purchasers, and the British Museum took no part in it. Few of the books that were sold in those years went out of England; they mostly passed into the hands of collectors, at whose death it was expected that they would again come under the hammer of the auctioneer; and the varying prices of even the most coveted books showed the expediency of waiting in many cases till the fever of the day was over. The Roxburghe copy of the 'Valdarfer Boccaccio' itself, which had gone at the sale for 2260*l.*, sold for less than 1000*l.*,

ARTS AND SCI. DIV. VOL. V.

when it was a second time in the market, and the early editions of the classics, about which the contest was then carried on most warmly, have since descended considerably in the scale of commercial value. With many other bibliographical rarities, however, the market has risen; and it has risen most remarkably in English books of almost every character of the date of the 16th century, and in foreign books, such as Roman Catholic liturgies, connected with the history of the old religion, and of the Reformation in England. Another, and a world-wide influence was next to come into operation, to raise, in the language of political economy, first the supply of English books, and then the demand for them—an influence which will probably work as great a change in the commerce of books as in that of cotton.

A hundred years ago, at the accession of George III. in 1760, the English language is supposed to have been spoken by about twelve millions of persons. In the year 1860 it is probably spoken by not less than sixty millions, and each year adds to the census of those who speak it a number as great as the whole population of those who speak some of the secondary languages of Europe. The French and German languages, which at the commencement of the century far surpassed it in that respect, are now far below it. Russia is the only form of speech in Europe that owns at present a larger number of speakers, having about sixty-five millions; and if the advance of population continues for a few years as before, Russian will be outnumbered. The English language is at the same time the vernacular of a great kingdom in Europe, and of great colonies in America, in South Africa, and in Australia, all of which are growing and some are rushing into importance. But the dominion of the English language is not bounded by the limits of the British empire, wide as they are. It is also the language of a great republic, or rather cluster of republics, whose territories now extend from the Atlantic to the Pacific, and will probably in the course of another century be teeming with population. English is now spoken by more persons out of Europe than within it, and the disproportion is certain to grow greater every year. While in Old England it has yet been unable to supplant the Welsh in the course of centuries, in New England it has long swept from before it all trace of the languages of the aboriginal nations, except the books that were written for them by the missionaries of the 17th century.

This bond of community of language, which is often invoked in continental Europe as naturally leading to a community of government, did not prevent the Americans from commencing a war, in which they aimed at rendering themselves as completely independent of England as they were of France. Their political independence was secured by the treaty of 1783. For about forty years after, however, some of their ultra-patriotic writers were in the habit of complaining that their literary dependence was as great as ever, while at the same time, it was almost made a subject of national complaint, that a writer in one of the English reviews had inquired, "Who reads an American book?"

When American writers of remarkable merit really began to appear, their merit often found its warmest and sometimes earliest welcome in England, where the names of Irving and Cooper, Bryant and Longfellow, Prescott and Ticknor, Lucretia Davidson and Mrs. Stowe, are held in honour, not inferior to that which is paid to them in their own country. Irving and Bryant are the only two of these whose writings date back before 1820, and the reputation of Irving, as well as of Cooper, was powerfully aided by the voice of England. The truth is, that when the question was put "Who reads an American book?" no one either in England or America could clearly foresee the rapid development that was to take place in American literature, a phenomenon as striking in the field of literature as its political development in that of politics. The 18th and 19th centuries had been remarkable in Europe for the number of old established languages which had, after a long period of barrenness, at length burst into literary fertility. Before 1750 it might have been inquired with some truth, "Who reads a German book?" and the highest names in the latter half of the century were those of German authors. After the signal success of German, five or six other languages had emerged into an importance altogether undreamed of a century ago; but in every case of a fresh literature there had been a fresh language associated with it. As in North America the first example was given of one of the colonies of Europe rapidly emerging into a new and powerful state, so in North America the first instance occurred of one of the old languages of Europe giving birth to a new and important literature. The Spanish and Portuguese colonies, long anterior in date to the English, followed the Anglo-American example in one case, as they will do apparently in the other.

The circumstance of two literatures flourishing together in the same language is in an eminent degree fortunate for both. National prejudices are necessarily weakened, circumscribed ideas are necessarily widened, even by the mere enlargement of the literary horizon which is thus created. The sympathies of those who can read Dante and Schiller are not likely to be cold towards Italy and Germany; but how limited a number of English readers can be expected to master German and Italian, how different is the effect of reading a poet in the translation or the original. The American can enjoy every word of Shakspeare and Byron; the Englishman, of Bryant and Longfellow. When America had scarcely a writer of its own, its readers had access to the rich treasures of English literature, and educated by that

knowledge, its authors, when they came forward to contest the palm, stood on equal ground with those they had to encounter. A hundred and fifty miles from London there was in the meantime a Welsh population to whom Shakspeare and Byron were idle names.

The sudden rise and rapid progress of American literature made it necessary for any library, intended to embrace the whole wealth of the English language, to extend its plan and enlarge its sphere. Popular as many books of American origin became in England, to such an extent in fact that many of them formed part of the ordinary stock of booksellers' shops in country towns, it was chiefly through reprints that they circulated; and there were hundreds of volumes published in the United States of which probably not one copy was sent for sale to England. Histories of American country towns, genealogies of American families, biographies of American local celebrities, reports of American legal decisions, and so on, are books for which few men can find space in their libraries; but it is easy to see how to be able to consult a copy of such books, in particular cases, may be all-important to particular persons, and is always of value to those who compile or who cater for the public. An American genealogy will often throw light on the history of an English family; an American law-case may involve the acquisition or loss of property to English residents; the historian of the contests between England and America, or of our religious sects, or of our arts and manufactures, may often find something in American topography or biography bearing on his subject; to say nothing of the general interest attaching for its own sake to a nation so conspicuous in the eyes of the present world, and so important in all speculations of the future. This object has not been lost sight of by those who have had the selection of books for purchase for the British Museum; and indeed it is the opinion of competent judges that a more complete collection of American literature has been amassed there in the course of the last twenty years, than exists in any library of the United States.

The marked success of America, in literature, of course encourages the confident hope, already justified by more than one brilliant example, that other communities sprung from the English stock will, when the first cares of colonisation and settlement are over, give equal proofs of literary ambition and literary powers. In the meantime the productions of British America and Australia have already a strong historical value of their own, and are certain to derive an additional interest as the communities to which they belong advance in prosperity and importance. The collection of their different productions in one vast library would present a spectacle of interest to the whole world, of surpassing interest and pride to all who belong to what has been called the Anglo-Saxon race, whose triumphs in the field of literature are at least as noble as in any other.

The American movement in literature was followed by a movement on that side of the Atlantic, still more unexpected on this, and which indeed might well take Europe by surprise. The libraries of the provinces now forming the United States had received, previous to the declaration of independence, no scanty contributions from English liberality. After the war of the revolution there was a time in the new commonwealth when public libraries attracted little of the public attention. Dr. Channing, in a discourse in 1836, spoke of the Redwood library, at Newport, Rhode Island, as "yonder beautiful edifice, now so frequented and so useful as a public library, but once so deserted that I spent day after day, and sometimes week after week, amidst its dusty volumes without interruption from a single visitor." This state of affairs has been completely changed in the course of the last forty years, the movement proceeding with accelerated rapidity, in the last thirty, the last twenty, and the last ten. Numerous collectors have appeared who have expended large sums of money in the purchase of libraries of standard European, but more particularly of standard English, literature, and more especially of books relating, however remotely, to America. Some of these collections have been since dispersed on the death of their possessors, and some have even returned for sale to England. But several have been presented to public libraries, and others, which have been amassed at large expense, have been collected with the expressed intention of bequeathing them to public use. The subscription libraries of America, of which the first was founded at Philadelphia, by Franklin, in 1731, have grown numerous, and been remarkably supported by donations of money from individual members. On more than one occasion agents have been sent to Europe with thousands of pounds, supplied from private funds, to be expended in the purchase of books for public libraries; and on whole libraries occurring for sale in Europe, an individual has advanced the money to acquire them in a mass, and present them in a mass to some public collection. The "State Libraries" belonging to several of the states have, at the same time, been largely augmented at the public expense. A library of 80,000 volumes was collected in about four years, and has been opened to the public in New York, on the foundation of Mr. Astor, a German merchant, who made his fortune in America, and by the donations of his equally public-spirited son. Congress appropriated a sum of more than 100,000*l.*, left to the United States "for the increase and diffusion of knowledge among men," to the foundation of an establishment called the Smithsonian Institution, of which a library was to form a leading feature. In Massachusetts, a law was passed, in 1850, for the foundation of libraries in towns, and one has been set on foot and opened in Boston which has been

assisted by munificent donations, and keeps agents constantly employed in Europe. Two American writers, who have each published a volume of statistics on the subject, have thrown over it a somewhat ludicrous air, by giving the name of public libraries to the collections of books belonging to Sunday-schools and common schools, often of less than a hundred volumes, to which an Englishman would as little think of seriously applying the term as to our common circulating libraries, or the collections in our coffee-shops. Professor Jewett, in 1850, thus states the number of public libraries in the United States as 10,199, and the volumes in them as 3,753,964; and Mr. Rhees, in 1859, raises the number of public libraries to 50,890, containing 12,720,686 volumes. Striking off at a blow 48,000 of these public libraries, of which 30,000 belong to Sunday-schools, and 18,000 to common schools, the remainder will still excite our surprise. The effect of their existence has been to send an American agent to almost every important sale of books that occurs in England, and to every bookseller's shop, and to raise considerably the price of standard English literature not of the present day.

A movement analogous to that in America has already developed itself at an English colony in Australia, in which the rapid wealth flowing from gold-digging has been turned to the creation of libraries as well as railways. In the city of Melbourne, in the province of Victoria, founded in 1837, there are already a library of the Supreme Court, a library of the University, a library of the Legislature, and finally, a public library, supported at the public expense, founded in 1856, and counting in 1859, 25,000 volumes. At Sydney there is also a university with its library, and we have already heard of Caxtons that have been recently purchased in London, whose ultimate destination is a public library at the Antipodes.

These movements do honour to all who take part in them, and cannot be viewed by an English lover of books and literature without feelings of the warmest sympathy and admiration—not unmingled with a wish that the example they display may soon be followed in countries where perhaps it ought to have been set. These sentiments of gratification would be unmingled if, in Great Britain and Ireland, there were two or three libraries possessed of a complete collection of English literature. It is unfortunately the case that as yet there is not one. The danger is therefore evident that, under these circumstances, such a collection may possibly never exist—that such of our books as are unique, or only extant in a small number of copies, and are not yet secured in our public libraries, may be lost to them for ever. The first edition of the 'Pilgrim's Progress,' which differs considerably from the second, is now so scarce that Macaulay, in his life of Bunyan, speaks of it as no longer extant, and in fact only two copies are known to exist. Were one of these in the library of the British Museum we might not only hear with indifference, but with pleasure, that the other is at New York.

It is quite possible that, ere many years are over, an English scholar, who is in search of a rare English book, may be referred for it, not to Oxford or to Althorpe, but to Washington, or San Francisco, or the Antipodes. When, less than twenty years ago, the increased grant was given to the library of the British Museum, it was not given a moment too early, and on the liberality of the House of Commons to the Museum for the next twenty years, and the way in which that liberality is made use of, it will probably depend whether an English library, such as might have been collected with comparative ease at the beginning of the century, shall ever exist at all. That it should exist is the interest of all who enjoy the common inheritance—the English language, no less than the interest of the English nation.

In speaking of collections of books, the word "books" may be used in a limited or an extended sense. A pamphlet is scarcely considered, in common usage, entitled to be called a book. It would be thought by many that a complete collection of English literature had been formed when the jurisprudential department was such as may be found at our Inns of Court; the medical, such as exists in the College of Surgeons; the Church of England theology, such as at Sion College; and so on, going through all departments. A collection resembling this was probably contemplated by Sir Thomas Bodley, and in rejecting plays he assumed, as we have seen, that he was only rejecting trash. All men now smile at his error, because we find that in so doing he rejected the plays of Shakspeare, but many who smile would fully agree with more recent curators of the Bodleian in rejecting novels. In fact, there was no public library in England in which such works were admitted, at the beginning of the present century, and the bibliomaniacs who gave high prices for Lodge's 'Rosalind,' and Lilly's 'Euphues,' would probably have looked on the proposal to collect the novels of Mrs. Radcliffe or Charlotte Smith with ineffable scorn. Even now the new school of biographers is probably in a minority, which maintains that books like these should be carefully collected, preserved, and catalogued. The grounds upon which they rest are several. These books are generally very short-lived. Nothing is so difficult to find, if it happen to be wanted, as a novel that was in everybody's hands some years ago, for being in everybody's hands it was the more liable and likely to be pulled to pieces. About thirty years after its publication, a search for the first edition of 'Waverley' was long ineffectual, till a copy turned up in private hands. We have been told that at the library of the British Museum, a collection of old novels of a certain period was long a desideratum, till about fourteen

hundred volumes appeared in an auction, catalogued without specification as "Old Novels," in lots of forty volumes each, and were bought for the Museum at less than a penny a volume, probably the cheapest purchase ever made for the national library. The best novels are now admitted to form one of the very best portions of English literature. Of the 'Vicar of Wakefield' and of 'Waverley,' few will deny that the national library should contain the early editions, those that passed under the author's revision, and those which present peculiar characteristics, special illustrations or special notes. After such books as these there come hundreds of novels of the second, and thousands of the third class—stories which have had their season, which have been read with interest, laid aside and forgotten,—but some of which after being nearly forgotten have revived again, and have been discovered to possess merit greater than was at first imagined. Novels have been for the last fifty years, at least, the field in which most of the genius that was formerly devoted to the drama has sought its exercise, and it was the opinion of Sir Walter Scott that that field was rich indeed in buried treasure. It is to novels in fact that most of us owe our knowledge of the forms of life around us with which we do not come in immediate contact—it is in them that the lawyer can study the life of a man-of-war, and the midshipman that of a country parsonage or a cathedral town. The time may come when future generations will look back to the English novels of our own time with as ineffectual emulation as our generation on the drama of the Elizabethan age. But in regard even to volumes of which the merit is not discernible, the new bibliographic school is at variance with the old. It contends that while it is one part of the purpose of a great public library to preserve a copy of every book that people take pains to collect on account of its value, it should be another part of its purpose to preserve a copy of the books which nobody takes pains to collect, because they are therefore almost certain to disappear. There is no knowing beforehand what adventitious interest may come to attach to a book from particular circumstances. Anonymous novels and romances of no intrinsic merit cannot but wear a different aspect in our eyes when they are known to have been written by Theodore Hook or Shelley, as a commonplace anonymous review of Wordsworth in an old magazine is scanned with an attention its merits little deserve when discovered to be by Byron at college. In all the minute biographies of our recent great authors—in those of Byron, Walter Scott, Moore, Southey, Wordsworth—the reader finds indications of this kind which invest with interest books and fragments that he might have been previously inclined to pass without notice.

If the arguments of the new school are allowed to be valid in the case of "trash," they are certainly not less forcible with regard to "lumber," of which they no less warmly advocate the collection and preservation. Perhaps the shortest method of arriving at a clear view on the subject of "lumber" will be to examine the bearings of a particular case.

The 'Times' newspaper is the most effectual organ of publicity that now exists, or has ever existed in England. On the day of its publication, an article likely to interest the Queen will probably meet the eye of the Queen,—an article touching on the law will be scanned by the bench and bar; a paragraph on public houses will come under the notice of twenty thousand licensed victuallers. Myriads of copies are read by hundreds of thousands of readers at the places of public resort. On the day after its publication it has passed into comparative obscurity; in the week after it is difficult to procure a copy if one is wanted for a particular purpose; in the month after, it can only be consulted at particular places; in a twelvemonth after, of the myriad copies that have been issued, how many remain? The great majority of its readers have done with it for ever on the day of its publication; few private individuals think of preserving it, and those few soon discover that the task is more burdensome than they supposed, that it involves expense and trouble which are continually increasing, and that merely to find room for the volumes is an oppressive tax. Even in coffee-houses and other places where customers are attracted by the announcement that files of newspapers are kept, it is the general practice to destroy them at the end of about ten years, lest the accumulation should drive the accumulator out of house and home. Nothing of a literary kind attracts more universally the reproach conveyed in the appellation "lumber" than the files of an old newspaper. The natural results follow. The most insignificant book of which twenty copies are printed is almost certain to be in existence somewhere at the end of twenty years, but it is quite possible that in the course of that time every copy of one day's edition of the most widely circulated newspaper in Europe may be consigned to destruction. There are numerous reasons why the disappearance of nine hundred and ninety-nine out of a thousand copies of the 'Times' should be looked on without any disfavour whatever, as in fact equally natural and necessary, but there are also numerous reasons why the thousandth should be preserved. It is a record, the possible importance of which can hardly be overrated. The persons who have to consult a set of the 'Times' for a particular piece of information—and who may not suddenly require to consult it!—for an advertisement for next of kin, for the record of some long past marriage or death—may, if a single number be wanting in a set, throw away all the tedious labour of hunting through the ponderous volumes of years. An old number is sometimes in request for literary purposes. An anecdote

told in 'Moore's Diary,' that a poetical *jeu d'esprit* in a number of the 'Times,' at the period of the Reform Bill, was attributed at Rogers's breakfast-table to Moore, and on being denied by him was acknowledged by Macaulay, has led, since Lord Macaulay's death, to a search after the forgotten poem in the set of the 'Times' at the British Museum, to be transferred from the unwieldy columns to a place in the posthumous works of its illustrious author, which will find their way in some edition to almost every library in Christendom. If it be granted that it is desirable that a complete set of the 'Times' should exist, it can hardly be doubted that it is desirable it should exist in a public library. Such a set in the possession of a private individual could not well be made available for one-half of its proper purposes, even if with the most transcendent good-nature he should be willing to entertain at his own expense every application made to him. There must not only be the store-rooms or cellars to place it in—and there are now twelve folio volumes a year—but the room to examine it in, the large strong tables to place it on, the attendants to bring and remove the volumes, as they are wanted or done with. But does such a set exist either at the British Museum, the 'Times' office, or elsewhere? It is no part of the general economy of newspaper offices in London to take such things into account. At the office of the 'Morning Chronicle,' which is one of the oldest London papers, there is no set of the 'Morning Chronicle,' and at the office of the 'Daily Telegraph,' which is one of the newest, there is no set of the 'Daily Telegraph.'

Supposing the set to be imperfect at a public library and pains taken to complete it, how thorough an illustration would the process probably afford of the usual joys and sorrows of the management of a library? In such cases catalogues have to be searched to ascertain when any volumes of the 'Times' will occur for sale; when they do, attention is to be given to procure the information, often not easy to be obtained, if "with all faults and errors of description," they really contain the missing numbers. Care must be taken not to let it be known too widely that the numbers are wanted, lest some bookseller should take advantage of the knowledge to secure them for himself, or run up the price. Even under the most favourable circumstances the price may accidentally ascend so high that the librarian may doubt if he is justified in expending the money in the purchase; and those who think his proceedings worth notice, without understanding them, may criticise him for the extravagant style in which he wastes the public money. When the numbers are secured,—when finally the set is thoroughly complete—comes the tedious task of the incorporation of the new acquisitions, the disposal of the duplicates that have in all probability been necessarily acquired, and the crowning joy of the alteration of the entry in the catalogue from "'The Times' from 1788 to 1859, wanting such and such numbers," to the simplicity of "'The Times' from 1788 to 1859 complete." When this consummation is achieved, the librarian's toils are naturally forgotten, and every subsequent reader assumes, as a matter of course, that the volumes, to use an expressive phrase, "grew on the shelves." It is well for the librarian if the history terminates here; but the annals of the British Museum inform us that some years ago a writer, admitted to all the privileges of that magnificent institution, being engaged in writing a life of Daniel O'Connell, for which he required some extracts from the newspapers, took his penknife instead of his pen, and to save himself the trouble of copying a few paragraphs, deliberately mutilated every volume of newspapers that was brought for his use. A man of this description may in a few days of undetected villany ruin the labours of years, and defraud centuries to come. Sets of the 'Times,' it may be observed, are evidently rising in the market. The library of the State of New York has acquired a set, though not a complete one; and we have heard, on good authority, that 1000*l.* would be given for a perfect set for the library of Melbourne.

Of course the argument in favour of the 'Times' will extend to many other of the London papers. The British Museum now receives and preserves them all, and in addition, all the English country papers, all the Scotch, and all the Irish. In the Museum returns for 1860, it is reported that in 1859, 584 were received from England, 113 from Ireland, and 125 from Scotland. They are sent from the Stamp Office, not at the time of publication, but a few years after; and they are attended to with the utmost care, bound and kept ready for instantaneous reference. A new use of them has lately been developed. An excellent example has been set in some of the northern counties of England, of publishing 'Local Records,' in which all the really memorable occurrences that have taken place in a particular district for about a century, are condensed from a hundred folio volumes of the local newspapers, into the compass of one or two octavos, easy of reference and abundant in interest to the resident or visitor of the different localities. If this practice spread, as it appears likely to do, the vaults of the British Museum will furnish matter for many a volume that will be popular at the fireside, and that must otherwise have remained unwritten. A still wider interest must attach to the annals of English colonies, than to those of English counties; and there can be little doubt that the prosperous communities of future times will look back to the struggles of their early period as mirrored in their contemporary records, with an interest akin to that felt by the grown man in the reminiscences of his childhood. It is to be regretted that, as yet, little has been done in this direction in the Museum Library. Unless current reports are ill-founded, a great statesman, who was also a

Trustee of the Museum, no less a man than Sir Robert Peel, who had himself been Colonial Secretary, once interposed his veto to prevent the innovation of collecting colonial newspapers. Neither at the Museum nor at the East India House, is there a collection of the English newspapers published in India, though at the India House a collection of the native newspapers was procured at the suggestion of the late librarian, Professor Wilson, the eminent Sanscrit scholar. A plan for collecting sets of all the American newspapers has never, we believe, been seriously entertained, the notion of assembling them too nearly approaches that formerly advocated by Dr. Anderson, of Glasgow, the ingenious editor of the 'Bee,' who wished to collect and preserve everything whatever in print—every shop-bill, every placard for a lost article, issued throughout Great Britain. The number is now estimated to be upwards of 4000. Sets of the leading American newspapers are of course desirable for the rest. An ingenious idea, put in practice by Mr. Charles Knight some years ago, with regard to the lower periodicals of London, would seem to be the most advisable plan to adopt with these multitudinous journals. He sent round on a particular day to collect one specimen of every periodical sheet that issued from the press on that day or nearest to it, and was thus enabled to draw conclusions as to the character and tendency of the whole body of contemporary periodical literature. A collection of the first number of every American newspaper and periodical issued in 1861, would be an interesting and a suggestive exhibition.

The same arguments that hold good for the preservation of newspapers, apply, and sometimes with additional force, to other varieties of transient literature—to that most ancient and most despised species of periodical publication the Almanack—to the Directory, of which the annihilation is carried on with such vigour, that it may be questioned if a complete set of the 'London Directory' exists in London. But even in the most respected forms of periodical publication, the long continuance of their success, in point of time, renders their presence onerous in point of space. As no English newspaper has, like some of its Dutch, German, and Swedish contemporaries, lasted over two hundred years, so no English magazine has, like the French 'Mercure,' ever extended to more than a thousand volumes; but the sets of the 'Monthly Review,' and the 'Critical Review,' and the 'Universal Magazine,' and the 'Scot's Magazine,' to mention none but those which are defunct, are too voluminous each of them for libraries of ordinary size, while the combination of all of them, and of hundreds more, in some one locality, is as necessary for use as it is difficult of accomplishment. In fine, all those who have had experience of making research in any department of knowledge whatever, have found reason to complain that the stores of English literature in the British Museum, ample as they seem, and as in many respects they are, are still too scanty by far, and that much that is attainable remains to be attained.

The English is not the only language of the British Islands; and apart from the interest which must always attach to the Welsh as the early speech of at least part of the country before an Anglo-Saxon set foot on its soil, that language may claim to be one of the oldest of modern Europe, and it has been cultivated to a high pitch of refinement by a small community, overborne by an overwhelmingly powerful neighbour. It is singular that the literary cultivation of the country has never developed itself in the direction of bibliographical collections; for the concentrated diligence of a few years, combined with a moderately liberal expenditure, would probably have sufficed to assemble a complete collection of Welsh printed literature, the possession of which might have conferred celebrity on a local society or a local magnate. Nothing of the kind appears to have been done on a scale approaching completeness; and the largest Welsh collection now known is that of the British Museum, with which the scanty libraries formerly belonging to the Welsh School, and the Cymmrodorion Society, have been incorporated. So little does its existence appear to be known in Wales, that we find, in the 'Life of the Rev. Thomas Price,' an eminent Welsh scholar, some bitter complaints of the total neglect of Welsh literature at the British Museum, at a time when more attention was paid to it there than anywhere else. Compared with Welsh, the literature of Gaelic and Irish is excessively scanty; but Gaelic has to boast of one name, Ossian, which is famous throughout Christendom, though the Gaelic poems printed under his name are of course no more genuine than the English so-called translations, which are in reality the originals. The best collection of books in Irish is in the Grenville library at the British Museum, amid probably as extensive a collection of Irish books in English as is anywhere to be found; but both Gaelic and Irish are languages to which more attention might be paid with advantage. There is a complete bibliography of Gaelic books in Reid's 'Bibliotheca Scoto-Celtica,' which might serve as a guide for collecting them.

In every great public library formed with a view of affording means for the acquisition of sound and substantial knowledge, the foreign books will far outnumber the native. One of the so-called dead languages was for ages after its death the language of all living literary Europe, and the treasures contained in it are in consequence remarkable for quantity as well as for quality. Since the revival of literature, though different languages have predominated at different times, and some which have shone have had intervals of obscurity, the number of languages in active cultivation has constantly been on the increase. After the invention of printing, Italian was the first vernacular language

to produce works of remarkable genius, and even before the invention of printing it had already had a time of flourishing and a time of decay. Spain followed, in the age of Charles V. Towards the close of the 16th century England had its Elizabethan age. The 17th century produced Richelieu and Louis XIV. for France. It was Richelieu who first definitively formed the project of the dethronement of Latin as the general language of serious learning, and the establishment of French in its place. His plans had singular success for a period, and French is still the most general medium of intercourse in Europe; but the great effect has been, not the introduction of a living language in the place of the dead one, but the general adoption of each living language as a literary medium by those who speak it. This system has been becoming more and more general since about the year 1750, when the Germans may be said to have abandoned Latin for German. At present there are at least six European languages in cultivation—Danish, Swedish, Russian, Polish, Bohemian, Hungarian—which a century ago might have been neglected with impunity by the literary student. Russian might always have been expected to rise into importance as the plans of Peter the Great took effect; but Bohemian and Hungarian were then regarded, even by those who spoke them, as likely to pass away in a course of gradual decay.

It may be of advantage to take a rapid survey of all these literatures in succession, with a view of ascertaining what large collections of them have been formed, either on their own soil or in the great libraries of Europe, and more especially in that of England.

The three dead languages which have been the great objects of study had, till the recent revival of the separate kingdom of Greece, no particular spot where they might claim in modern times a "local habitation and a name." The literature of the Hebrew language has been, like the Hebrew nation, scattered over the world. A language which has been dead since the Babylonian captivity, which had long ceased to be spoken when the New Testament was written, is cultivated with sufficient energy in the 19th century to supply materials for a modern bibliographical periodical, published at Berlin—the 'Hebräische Bibliographie.' The first book printed in Portugal, and the first book printed in Turkey, was a Hebrew Pentateuch, and it was probably also the first printed in several Mohammedan countries, where the art was permitted for the reproduction of the Bible, though forbidden for the reproduction of the Koran. Jewish literature is not, however, confined to comments on the Bible, and is of far more extent than has often been supposed. Mr. Wilson Croker, on his examination before the royal commissioners on the British Museum, expressed his belief that there were no books in print exclusively Hebrew without a Latin explanation of some sort. There were at the time more than 4000 of that description in the British Museum, comprising not only editions of the Bible and commentaries, but Jewish plays and Jewish epics. The fate of Jewish libraries has been singular. The two largest now in existence are said to be those formed by Rabbi David Oppenheimer in the 17th century, and by Mr. Michael of Hamburg in the 19th, of which the first and largest is now in the Bodleian library, and the second in the British Museum. Formed in Germany, and both preserved at Hamburg, they have both been transferred to England, and Oxford is now become in particular the place of pilgrimage to Jewish bibliographers. The collection at the Museum is being constantly augmented with accessions from quarters from which no other accessions come—from presses in the Crimea, among the Karaites, from obscure villages in Russian Poland, from Africa, and from Turkey. The number of volumes in the Museum collection was stated by its librarian, Mr. Zedner, in the 'Hebräische Bibliographie' for 1859, to be 7480.

Still more full of life than the Hebrew is the Greek literature, tracing its illustrious course through the long ages from the foundation of the first public library in Europe by Pisistratus at Athens, before the war with Xerxes, to the foundation of the library of the university of Athens in our own time, after the rescue of Greece from the Turkish yoke. Till the 19th century few Greek books could be printed on the soil of Greece, and those few were in the modern Greek—a language into which the 'Iliad' itself had been translated before the fall of Constantinople. Of the books printed in ancient Greek in different parts of Europe in the four previous centuries, there are many good collections extant. These books were always esteemed of value; they were eagerly sought after for great libraries at an early period; in the 18th century they brought high prices from scholars and bibliomaniacs, and were looked upon as the choicest of the early productions of the art of printing. There is an excellent collection of them in the British Museum. There is in the same library a collection, less valuable and more rare, of books in modern Greek, brought together by Lord Guildford, the warm friend of the Greeks and founder of the university of Corfu. When his library was sold, at his death, this collection was acquired in a mass by the Museum; and though it is by no means complete, it contains perhaps more than any other of the works described in the bibliography of Iken and Papadopoulos. These books are curious for tracing the history of the backward stages of the modern language, which has been becoming every year more and more ancient.

An immense and important portion of every library worthy of the name must be formed by works in the Latin language. By those who declaim against the study of Latin, as a sacrifice of valuable time to the acquisition of a mere knowledge of the literature of the heathen

Romans, it appears to be forgotten that Latin was for about fifteen centuries the language most intimately connected with the history of our own country, as well as of many others. It was in Latin that Caesar wrote his account of the discovery of Britain; in Latin that the Saxon Bede composed his valuable history of the English church; in Latin that the monkish chroniclers, Saxon, Norman, and English, compiled their records of contemporary events for century after century. It was the same with France, with Italy, with Spain, with Germany, with Scandinavia. In Poland and Hungary and Holland the usage of Latin continued still later, and the parliamentary speeches of Hungarian magnates almost up to our own times, and the lectures of Dutch professors even now are delivered in the language of Cicero and Caesar. The early productions of printing were mostly in Latin, and for long afterwards the appearance of literary Europe was that of a learned republic, in which Latin was the predominant speech, and the modern languages merely took the position of provincial dialects. The libraries of mark throughout Europe were chiefly filled with Latin, and it might almost have been expected that the happy idea would have occurred to some great potentate to collect together all the Latin books that kept pouring from the press in the different parts of Europe. It was towards the close of the 15th century that King Matthias Corvinus, of Hungary, applied himself to the task of collecting a magnificent library, for which his expenses were truly regal, amounting according to some, to 30,000 florins a-year. He is said to have kept thirty copyists constantly employed; and at his death, in 1490, his collection is stated to have amounted to nearly 55,000 volumes, "almost all manuscripts." Had this expenditure been recorded of a monarch who died in 1390, or before the invention of printing, our admiration might have been excited in a high degree, but it awakens wonder that admiration should be claimed for a monarch who expended treasures in multiplying manuscripts after he had himself invited the first printer to Buda. The proceedings of King Matthias, however, are still pointed to by some modern writers with unalloyed panegyric. When the collecting of books first came into fashion, the early printed Greek and Latin volumes were those most sought after, and large collections were made of "incunables," or "cradle-books," as those are technically called which were issued in the infancy or cradle-times of printing. The first editions of the classics, however, were those which attracted the most attention, and other works of the 15th century were comparatively neglected. In Panzer's valuable catalogue of the books printed before 1535, a work which, including the German part, extends to thirteen quarto volumes, he is obliged to refer to numerous libraries as the depositaries of the various treasures which he describes from numerous catalogues. There is no library in Europe which approaches to containing them all. Yet there are still floating about Europe so many copies of volumes of the period referred to, not only for sale, but often for sale at very moderate prices, that the steady adherence of a well-provided library for some years to the rule which has, it is said, been adopted by some, of buying every work not in its possession printed before 1500, would probably have a very considerable effect. Four hundred years, and more, have not cleared from the booksellers' shelves the copies of many books which were only printed, it is said, in editions of less than five hundred copies: but here again it is more than probable that the next fifty years will effect more than all their predecessors have done.

After the literature of the language of ancient Italy, that of the language of modern Italy appears to have entered the earliest into general circulation. In the days of Elizabeth and the early Stuarts, a knowledge of Italian was more common in England than it has ever been since, and for part of the time it was the popular language of the court of France, which was as usual governed by female influence, and was then under the guidance of Italian princesses. There has therefore always been a tendency for Italian books to find their way out of the country, as well as Italian paintings. At the same time the division of Italy into so many rival and hostile states has had a singular effect in preventing the circulation of its literature within its own boundaries. It has often been the case, that Milan did not know what books were issued at Naples, and Florence was a comparative stranger to the current literature of Rome. The same division in Germany has been productive of exactly the opposite effects, and has led to an organisation of the book-trade superior to that which prevails in France and England. From the same cause there appears to have been no marked attempt in any Italian library to form a complete collection of Italian literature: the strong local attachment which has been sufficient to preserve in use a host of different dialects, many of them often used for literary purposes, has, at least until the present generation, prevented the mind from being sufficiently expansive to embrace all Italy from the Alps to the sea. In many of the Italian libraries also the books appear to have been kept in singular subordination to what should have been their accessories; in the Vatican library not a book is visible till presses have been opened, and the historians of its progress dwell most on its architecture, its paintings, and ornaments. The result has been that the great libraries of Paris and London are probably richer in Italian literature than any within the bounds of Italy, and that in that literature much apparently still remains to be discovered. Roscoe, the historian of Lorenzo and Leo the Tenth, expressed his surprise that after a careful study of his authorities it should still be in the power of a Bristol collector, Mr. Bright, to show him a volume of Italian popular poetry,

on the battle of Pavia and other contemporary events, of which he had never seen mention, and the like of which he had no reason to suppose ever existed. There are only two copies known of a contemporary Italian popular poem of the discovery of America. They are both in the British Museum, for which both of them were bought at different times at sales in Paris. It should be added, that both the sales were of the libraries of Italian collectors.

The literature of Spain, like that of Italy, early attracted attention abroad. Spanish was for a time the language of the court of Vienna, cultivated in France and England, and well known in Italy. There is something peculiarly original and racy about many of its productions: its romances of chivalry, its ballads, its histories of wild adventure in America told by the adventurers themselves, its final comic romance of chivalry destined to throw all the others out of the saddle, its drama that followed Don Quixote, though much of it was as romantic as Amadis de Gaul. But along with the very earliest of this literature grew the weed that was destined to choke it, and the decline of Spanish letters kept pace with that of Spanish power. There is perhaps in no other European language, except possibly in that of Portugal, so great a proportion of worthless books as in that of Spain. The most ardent collector cannot but shrink from the prospect of encumbering his shelves with much of that kind of literature which flourished in Spanish convent libraries till their dissolution in 1835. Meanwhile the fate of Spain in regard to books has been signally unfortunate. Careless of bibliography themselves for a long period, the Spaniards have at length awaked to find that much of their most valuable early literature has left their shores for England, France, Germany, and the United States. In the critical editions which, much to their credit, they are now publishing of Lope de Vega, of Calderon, and others, they are often driven to confess their inability to find at Madrid copies of editions which are irrevocably fixed in the public libraries of Paris and London. A Spanish bibliographer of eminence was accustomed to say that the extravagant prices given at some English sales for a few favourite books were some of the most profitable investments that English capital ever made; for the effect had been to draw to the London market from Spain a mass of volumes which, once being there, were obliged to be sold for what prices they would bring, and brought much less at London than they would at Madrid. It was at one time much easier, he stated, to find rare Spanish books in England than in Spain, and some that now adorn the Peninsula were redeemed at low prices from English book-stalls. The Spaniards are probably not at the end of their calamities of this kind. They set us the example of planting colonies beyond the Atlantic, and there are nations which speak the Spanish language which will, in the natural course of things, begin to draw literary treasures from Spain. If their political troubles have hitherto retarded the progress of literature among these nations, the fact of their speaking Spanish has produced an interest in that language among their English-speaking neighbours which has already borne its fruits. The best recent contributions to the history of Spain and Spanish literature have come from Boston, in Massachusetts. On the whole it should be the aim of Spanish bibliographers to centralise the collections they still retain, and guard against further loss by establishing as far as possible a complete national library, in which they should also collect the Spanish publications of South America and Mexico.

Portugal stands in much the same position as Spain, except that its books have never been so much in demand abroad as those of its neighbour. By the breaking up of the libraries of the convents, the national library, established at Lisbon in 1796, has been considerably enriched; but Senhor Innocencio da Silva, the author of the excellent bibliographical dictionary of Portuguese books now publishing, remarks in almost every page that some book he is describing is not to be found in the national library. Of many of the books he has only to mention that they were in the library of Lord Stuart de Rothesay, which was sold a few years ago in London. At that sale, extensive purchases were made for the British Museum, which already possessed some of the finest and rarest works in Portuguese literature, by the accession of the King's and the Grenville libraries. The 'Cancioneiro' of Resende, the first two editions of Camoens's 'Luciad,' the early editions of Barros and Castanheda, the Hebrew Pentateuch, which was the first book printed in Portugal, are probably united in no other library, and they are here associated with a good collection of general Portuguese literature, not wanting in the recent productions of both Portugal and Brazil.

France and England have now been in close connection, whether as friends or foes—but always as rivals—for about 800 years, and the contest which has been carried on in many a field in Europe, Asia, and America, has been carried on in the field of literature also. For about the first 400 years, up to the invention of printing, the French language flourished in England, and our libraries are rich in manuscripts in that language, many of which were written by Englishmen; for part of the last 400 years the French language has often been more widely known and more extensively used in countries with which France had scarcely any connection, in Russia and Poland, than among its insular neighbours. Printing flourished in France from the moment that a German doctor of the Sorbonne invited German printers to Paris—it rose at once into elegance, and began from the first to command a foreign market. There are books in English printed for Anthony

Verard, of Paris, and some of the choicest volumes in the library of King Henry VII., of England, now in the British Museum, are volumes on vellum, printed for the same Verard. The contemporary library of the kings of France is not so rich in specimens of the Paris printer. In France, indeed, as in other countries, the books in the national language appear not to have ranked in such high estimation for "library books" as those which were in foreign languages, or were brought from abroad—were in Greek or Latin, or came from Italy. It was in France, however, in 1556 that the idea appears to have originated which has since been imitated in every country—free or despotic, monarchical or republican—of levying a "royalty" upon booksellers of one or more copies of the works they printed. Henry II., in 1556, issued an ordinance that a copy of every book issued in France should be deposited in the Royal Library. Had this order been always obeyed, and had the books thus obtained been always preserved, a great good would certainly have been effected; but in all countries, free or despotic, these orders have been often disobeyed—a fate which they probably share with all other orders, but in this case the effect of the disobedience, instead of wearing out, becomes more perceptible with the lapse of centuries. Without such a regulation, however, no very large assemblage of French literature would probably have been formed in France at all, for the great collectors of libraries in that country, in the 16th and 17th centuries, seem to have had their thoughts turned more to the acquisition of beautiful copies, on vellum or large paper, in magnificent bindings, than to the formation of complete sets of the sources of information in any branch of literature, knowledge, or history. It is related of the great collection of the President De Thou, that the owner, in some instances, supplied paper of his own to the printers of a book for a peculiar copy to be struck off, that he bought several copies of a volume to pick out from many the best impression of particular sheets, and finally that he bound his library so sumptuously that when the collection came to be dispersed the books were sold for less than the cost of the binding. With all due appreciation of "a choice Thuanus," those who do not regard a book merely as a piece of furniture, must be permitted to smile at some of these particulars. The age of Louis XIV. spread through a large portion of Europe a taste for the French language and literature, which became so exclusive and prevailed so long, that, as is well known, the library of Frederick the Great consisted entirely of volumes in the French language. This taste, however, was almost exclusively for books of the age of Louis and after it, and led to no dispersion out of France of the productions of an earlier period. Indeed, in France itself these productions were looked upon with disregard till long after a fervour had been awakened in England for Caxtons and Wynkyn de Wordes. As the Elizabethan age preceded the age of Louis XIV., and as the English Commonwealth preceded the French republic, so the age of enthusiasm for black-letter in London preceded that age of enthusiasm for black-letter which now prevails in Paris. The present period in France is equivalent to the period of the Roxburgh sale in England; and it appears to have had an analogous effect in preventing, for a time, French books from leaving France. Even when they have quitted the country they have in general only passed into the hands of Frenchmen, as, for instance, the library of M. Cigogne, which has in this year (1860) crossed the Channel to join the library of the Duke of Aumale, at Twickenham. There is still hope of recovery of these for the great library at Paris, but it has not always succeeded in obtaining the rarities of ancient French literature which have been first discovered in other parts of Europe. Until the year 1845, only five or six of the French farces of the 16th century were known to exist in different libraries in France, and the best French bibliographers, even those who gave their special attention to dramatic literature, had heard of no more. In that year a volume was discovered at Augsburg, containing sixty-four dramatic pieces of this peculiar kind, and it was sold by Mr. Asher, the German bookseller, to the British Museum. The French antiquaries could not at first believe that the volume was genuine, but all doubt has been removed by the publication of a transcript from this unique and remarkable volume at Paris.

The extent and variety of the literature of France in the 18th century drew from Dr. Johnson the emphatic commendation that they "had a book upon everything." To the intrinsic interest of that literature was added the fearful historical importance which it gained, by its having been followed by the great revolution which, in some of its phases, seemed too plainly to prove that nations may, like individuals, be subject to mental aberration. The pamphlets of that period found more than one Thomason, and extensive collections of them exist in the national libraries of both France and England. A large portion of the 'Moniteur' of those years has been since twice reprinted in its entirety, and is probably the only set of a newspaper that ever received such an honour. The history of France during the age of Napoleon, is so closely intermingled with that of England throughout, that many of the valuable historical works which have been issued upon it in France are desirable additions to any great English library, and the Museum ought to possess them all. The library at Paris, which has recently issued a catalogue, in many quarto volumes, of its collection of the history of France, appears, in this department, to be very complete, so far as French literature is concerned, but to have concerned itself but little with what has been written upon France by foreigners.

The literature of Germany is now with that of France, the richest

literature of the continent. It is one of the many fortunate circumstances which attach to the English language, that it stands midway between the two modern languages that contain the greatest amount of learning—that a person acquainted with English is by that circumstance half-acquainted with French and half with German. The history of the cultivation of the German language is striking. Singularly rich in capabilities, spoken by a great, powerful, and enlightened nation in the centre of Europe, it was for centuries neglected at home and despised abroad. It was not till about 1750 that it emerged into cultivation by native genius, and not till half a century later that it became an object of liberal study with foreigners. It is now in England the language that is most cultivated after French; it is studied in France and Italy, and is even penetrating into Spain. Always renowned for learning, its learning till about 1750 was chiefly couched in Latin, and the most ardent patriot could not imagine that its literature stood on a level with that of several foreign nations. At present, not to read German prose is to be excluded from one of the main sources of liberal information; and not to read German poetry to be shut out from the enjoyment of some of the happiest productions of genius. Professor Porson, in the early part of this century, produced a laugh by the observation that "life was not long enough to learn German"—but the laugh which is now excited by it is at Porson's expense.

Germany has always been remarkable for its numerous and extensive libraries, for the diligence, perseverance, and minute attention of its book-collectors, and for the admirable arrangements of its book-trade, in which by the agency of a book metropolis, Frankfurt or Leipzig, the most active circulation has always been carried on between the heart and the extremities. It might therefore have been anticipated with some confidence, that in Germany complete collections of German literature would be found to exist. This is far from being the case. We frequently hear at the present day of collections of early German literature in private hands which contain works not in the public libraries. A few years ago the collection of Herr Von Meusebach, consisting of 36,000 German volumes, was bought in a mass for the library at Berlin—and the acquisition was spoken of as one that was absolutely necessary to place the German department in a satisfactory condition, and as giving the library at Berlin a superiority over those of Munich and Vienna. When in 1845, a large selection from the collection of Kuppitsch, a bookseller at Vienna, was bought for the British Museum, it soon turned out that some of the books thus acquired were unique, and a reprint has since been issued in Germany of one of the works of Fischart, a German humorist of the 16th century, from the Museum copy. In the catalogue of the Museum issued in 1813-19, the names of Goethe, Herder, and Lessing do not occur; and Schiller is mentioned only in connection with an English translation of the 'Ghost-seer.' The presentation of the library of George III. first brought to the Museum a creditably extensive collection of German literature and history, for which it probably was partly indebted to the taste of his German queen. That collection has since been increased at least twenty-fold. The Museum has acquired more than thirty-thousand German volumes in the course of the last ten years. Much as the literature of Germany is cultivated in Russia and the north, and large as are the libraries of Petersburg and Copenhagen, the German library of the British Museum is now probably the finest out of Germany.

With German the series of languages closes, of which specimens may be expected to be found in the shops of foreign booksellers in London or in the foreign circulating libraries of the metropolis. The other modern languages of Europe do not make their appearance in England in ordinary literary commerce, and are not taught as a branch of education. With Dutch or Danish, or Swedish, it can hardly be expected that it will ever be otherwise; but Russia with its sixty-five millions of speakers, and the growing importance of its empire, may probably in the next generation play the same part that German has done in this. In the meantime the arguments that have been used with respect to augmentations of the national library, may be applied with increased force to the measure of providing it with the best literature of these languages. One of the great purposes of a national library is to assist the student. The nation does not merely provide books for the amusement or edification of the many, but also for the instruction of the studious few, that through the medium of those few the great body of the public may receive a benefit not otherwise attainable. A score of men who read Dutch or Danish, may, by having access to ample stores of Dutch and Danish literature, be enabled to keep an eye on all that has interest or importance for the English public, and bring it effectually forward.

Dutch is a language that has stores of much interest, both in old and recent times,—in the relations of its early voyagers, and in the large body of information on record concerning its empire in the East. There are also long sets of tracts or pamphlets of the 17th century, bearing on the commerce of the East and West Indies, and on the striking political events of that century in which Holland so gracefully terminated its long struggle with England by sending us the vindicator of English liberty. The Dutch have many libraries, but none of remarkable extent, and they have bestowed little attention on the collection and preservation of their own literature. The largest assemblage of the Dutch drama in existence has somehow found its way to the

imperial library at Paris, which in other respects is not rich in the literature of Holland. The largest collection of Dutch books anywhere assembled is in the library of the "Society of Dutch Literature" at Leyden, of which a valuable catalogue has been published. There is good reason to suppose that the British Museum contains the largest collection to be met with anywhere out of Holland, and that it does not yield to any library in Holland in this respect, except that of Leyden. The same language, called Dutch in one country and Flemish in the other, is, with small variations of dialect, common to Holland and Belgium, but neglect of the national language in Belgium, and the aversion which has often prevailed between the two countries, has prevented either from paying sufficient attention to the literature of the other, while at the Museum neither has of late years been neglected.

The ancient language of the North, which still flourishes in Iceland, and was by common consent till lately denominated Icelandic, produced in the middle ages a body of literature, much of which has, since the invention of printing, been given to the press in Iceland, in Denmark, and lately in Norway, while much more still remains in manuscript. The recently founded library of Reikiavik, the capital of Iceland, contains less of this printed literature than may be found in the British Museum, which had the advantage of receiving from Sir Joseph Banks a collection made during his visit to Iceland, and comprising some of the rarest volumes, acquired from the library of Halfdan Einarsson, the historian of Icelandic literature. To this have been added a collection offered to the Museum by the learned Icander, Finn Magnusson, and of late years everything of interest that has appeared in this very curious branch of letters. The older literature of Denmark has never yet been much sought after beyond the boundaries where the language is spoken. In its own country the collection made by Hjelmsterne, and presented to the royal library of Copenhagen in 1807, made the first approach to completeness. The Danish department in that library was then made a separate one, and the object of particular care; and about that time it might have been expected with some confidence that it would be the most complete collection of a national literature made by any nation in Europe. Danish was then spoken by no one beyond the dominions of the King of Denmark; his authority, though paternal, was despotic, and the law to deliver a copy of every book in his dominions to the royal library was so peremptory, that at first five copies were required. The prospect soon vanished. Norway was separated from Denmark in 1814, and took almost immediately to perplexing Europe by calling the language it speaks Norwegian, though the same idiom prevails at Copenhagen and Christiania, with some slight difference of pronunciation, which a patriotic Norwegian sedulously exaggerates. Of course the library of Copenhagen lost its claim to Norwegian books, and can, like other libraries, only receive them by present or acquire them by purchase. At the same time the Norwegian literature, since the separation of the countries, has become of more importance, though still of such small extent that it has been asserted that the expenditure of a few pounds a-year would procure a copy of everything issued in Norway. The British Museum received with the library of George III. a valuable collection of Danish books, which has of late years been carefully increased; and it probably at present surpasses every library out of Scandinavia in its stores of the literature of Denmark and Norway.

Sweden, like Denmark, has had no foreign competitor for its earlier literary treasures. In Schroeder's work on the earliest productions of the Swedish press, the books he enumerates are extant in a very small number of copies, and those copies are almost all described as existing in Sweden. In that country, as formerly in England, the principal library is not in the capital, but in the chief university—that of Upsal; and this collection, which far surpasses that of Stockholm, but is itself inferior not only to the royal library of Copenhagen but to the university library of that city, contains a large number of Swedish books; but has, like other university libraries, never been directed with a view to embracing a complete collection of the national literature. Sweden too, like Denmark, has suffered in this century a dismemberment. The conquest of Finland by Russia took from it a country in which, though the language of the uneducated classes was Finnish, the language of the educated was Swedish. Runeberg, the most popular poet now living in the Swedish language, is by birth and residence a Finlander, and has never been in Sweden. Few Swedish libraries are extant out of Scandinavia, except in parts of Germany and Russia which were formerly Swedish provinces, and none of these are probably so extensive as that now in the British Museum.

The literature of Hungary is almost entirely a growth of the latter part of the 18th century, and of the 19th. The language, a branch of the Tartar stock, was revived, when sinking into decay, by the exertions of Kazinczy, and by the attempt of the emperor Joseph to suppress it. It has now become the object of enthusiastic affection on the part of those who speak it, and who were congratulated on their possessing such a noble organ of thought and poetry by the great linguist Mezzofanti. The number of works published in the language in 1795 was 22, and in 1855 no less than 640. The fine library of Count Francis Szechenyi, which was given in 1802 as the foundation of a national museum at Pesth, has since grown to a collection which was stated in 1859 to contain 180,000 volumes, of which 36,000 were Hungarian books, and 20,000 of the remainder were books relating to Hungary. These numbers are no

doubt much exaggerated, but the catalogue of the original collection which was printed at Szechenyi's expense before the donation was made shows that he had amassed with uncommon care and success almost everything that related to the history, the topography, and the literature of the country. If the collection has been continued on the same scale, as it probably has been, it must present as complete a specimen of what a national library should be as exists in Europe. In the British Museum there is a fine collection of books on Hungarian topography and history, and also of books in the Hungarian language, which may be called an abridgment of the Szechenyi Museum. The Hungarian refugees who arrived in London after the failure of the revolution of 1848, must have been agreeably surprised to find arrived before them all their best authors and most distinguished periodical publications, in an abundance which showed that the frequent complaint of Hungarian patriots was not in this instance justified—that Hungary had not been overlooked or forgotten.

The success of other languages has led the Wallachians recently to attempt a national literature, which was commenced within the last twenty years by the translation of some popular French novels into Wallachian or "Roumanic," by a native princess. This not very promising beginning has been followed up by a host of other translations, and by a few original efforts, some of which appear to have merit. The political importance which has been lately attained by Wallachia and Moldavia has given rise to a flood of pamphlets and political writings; and the peculiar position of the Wallachian as a solitary Romanic language in the east of Europe, has lent it an interest that otherwise would scarcely belong to it. Most of the original publications in Wallachian are in the British Museum.

The Servian language has far other claims to notice in its beautiful and spirited ballads, which have attracted from their first appearance the admiration of all literary Europe. The Servian literature is collected with care in the libraries of other Slavonic countries, but there appears to be no public library at Belgrade.

The ancient connection of Bohemia with England by the marriage of Richard II. to a Bohemian queen, led to the introduction of the doctrines of Wickliffe from the university of Oxford to the university of Prague, and so to the cultivation of the national language in the struggle which ensued with the Catholic clergy. Bohemia was the first of the Slavonic languages which had a printed literature; but, after the defeat of Bohemian Protestantism in the Thirty Years' War, that literature was also attempted to be suppressed. A Jesuit father of the 17th century, is branded with infamy as having for many years collected Bohemian books for the purpose of destroying them, an attempt in which he had no common share of success. As in the case of Hungary, the Bohemian language was sinking into apparently irrecoverable decay, and yielding the ground it had formerly occupied to German, when this tendency was arrested by the exertions of native scholars, and for some years past the language has been growing more and more into literary cultivation. One of the chief measures taken by the national party was the establishment of a "Bohemian Museum" at Prague, to contain among other things a collection of Bohemian literature. Bohemian is not like Hungarian, an isolated language; and the recent Panslavistic movement has called attention to Bohemia and its literature in other Slavonic countries. The library of St. Petersburg was enriched in 1852 by the purchase of the library of Jungmann, the author of the great Bohemian dictionary, and the historian of Bohemian literature. The student of the language will find a good collection of Bohemian books of recent date, and some curious ones of an older date, in the British Museum.

The literature of Poland has been remarkably unfortunate. It had a period of cultivation almost contemporary with our Elizabethan age, but its early productions rival in scarcity those of Bohemia, for though they were not made the object of systematic persecution, the indifference of the Poles to literary treasures has been so marked, that most of their ancient books have been gradually consigned to destruction by mere carelessness and wantonness. When Zaluski in the 18th century, brought together his immense library, one of his principal objects was to amass everything that related to Poland, and it is stated that 20,000 of his volumes had reference to this subject, though the whole number of books in the Polish language in his library was less than 5000. Many of the books in this collection were unique, and to form a second collection approaching to it in completeness was out of the question. When, therefore, the whole Zaluski library was carried off, as has been already stated, to St. Petersburg by the Russians, the Poles sustained not only a great but an irreparable loss. On the second occasion of the seizure of the Polish libraries in 1833, the Emperor Nicolas was, it appears, considerate enough to direct that books in Polish and books on medical subjects should be permitted to remain in Warsaw. The Polish emigrants have since established a Polish library in Paris, and Prince Adam Czartoryski, the same from whom the Russians took the library of Pulawy, presented to the British Museum in 1833, a small collection of seventy or eighty Polish volumes. A few years afterwards, the movement commenced for increasing the Museum library, and it has now the richest collection of Polish literature out of Poland and Russia. To judge from the occasional complaints of Warsaw journals as to the defective literary communication between that capital and Posen and Cracow, it is not improbable that Polish books from the three literary centres of the Polish language under

three different governments, may be often assembled in London before they meet on their native soil. On that native soil many of the literary productions of the Polish 'emigration' are of course forbidden to appear at all, while at the Museum they are still but imperfectly represented, though care is now taken to collect them from the different localities where they appear, at Leipzig, or Poitiers, or Tottenham. Amid the convulsions of the continent, and the dangers and circumscriptions which surround Polish libraries in Poland, it is far from improbable that the future historian of Polish literature may have to seek some of his best materials in Great Russell Street.

The literature of Russia commenced in the year 1708. It was then that Peter the Great issued his new alphabet, an improvement on the old and clumsy Slavonic alphabet which it supplanted, but still retaining one of its worst defects, in a silent letter, which in every Russian volume wastefully consumes at least a sheet. Along with the alphabet the old Slavonic language was abandoned, and the Russian, which had hitherto been spoken, not written, became the language of literature. A collection of it was located in a very singular quarter. Denis, the author of the 'Introduction to Bibliography,' tells us in 1775, and again in 1796, in his account of the libraries of Italy, that in that of Modena was a collection of all the Russian books ever printed, and the statement is repeated in 1846, in Roncetti's Italian translation of Denis, a carefully edited book, with excellent illustrative notes. Meanwhile, with regard to the great Zaluski library of Warsaw, collected by a Pole, and rich in Slavonic literature, there is a disagreement among authorities as to the number of Russian books it contained, some stating that there were five, and others that there were only four. When the library was removed to St. Petersburg, and made the public library of Russia, measures were taken to remedy this defect, and in the official guide to that library, published in 1850, the number of Russian books, forming a separate department with a separate librarian, is stated at 40,000, and it has since been materially augmented. The literature of Russia is now in a period of gigantic growth, and some of its productions are individually of gigantic size. A single number of a Russian monthly or fortnightly magazine, is generally of the dimensions of an English quarterly review, and a periodical of the first class, of which there are several, presents its readers in the course of a twelvemonth with six or seven thousand closely printed octavo pages, in which are inserted as articles among the original matter, complete translations of such works as Prescott's 'Conquest of Mexico,' or Kingsley's 'Two Years Ago.'

It is one of the most singular literary phenomena of our time that this great movement is taking place among a nation of nearly seventy millions of population, and that it is in most other countries so thoroughly ignored. The Russian authors abound in talent, and some of them have manifested genius; their subjects are full of interest. If they treat of their own topography, it is that of so mighty a portion of the earth's surface, that it cannot fail to have a general bearing; if of their own history, it is so intimately connected in modern times with that of Europe in general, and England in particular, that a more intimate acquaintance with it is highly desirable. They are great travellers also, and there is much in their observations on our own and other countries that deserves attention. Their admiration of English literature is warm, but not indiscriminate; and while in Spain or Italy we might seek in vain for critics who appreciate our merits or detect our faults, the observations of Russians may perhaps anticipate the judgment of posterity. In matters of politics, their freedom of speech is greater than we suppose, and they write much on subjects of contemporary history. Of late years, a 'Russian Free Press' has been established in London, in which some of their most eloquent writers express their opinions altogether without restraint, and as these publications are known to be constantly read by the emperor, they exercise an important political influence in Russia itself. Beyond the limits of Russia there is now apparently no Russian library of great extent—that of Modena being anterior to the great movement in Russian literature—except the collection in the British Museum. Four or five-and-twenty years ago, a solitary English student who had set himself to master the Russian language, found himself thrown entirely on his own resources for prosecuting the study of its literature. It was the same, not only with Russian, but with Polish, with Bohemian, with Servian, with Hungarian, with Dutch, with Danish, with Swedish—in short, with all the secondary languages of Europe. No large collection of any one of them then existed in England, unless possibly in private hands. No large public collection of any of them is known now to exist in England except under one roof, that of the British Museum, and there they are all assembled. Small as has been the cost of amassing it—less probably for the whole, than was given at Paris a few years ago for a single one of Marshal Soult's 'Murillos'—it is a collection unrivalled of its kind in Europe. The poorest student who has access to the British Museum has now access to unlimited stores, of which he has only to bring the key.

The literature of Russia is one of the most recent, the literature of its bordering empire, China, is the most ancient, to which the art of printing has been applied. It is no less strange than true, that that admirable art was first invented in the country of all the world to whose language its benefits are least applicable—in a country destitute of an alphabet—and that while exercised there for centuries, it never penetrated into the neighbouring states of India, a land of literature

and civilisation, with the most perfect alphabet in existence. The date of its first discovery is stated by M. Stanislas Julien, the eminent Chinese scholar, to be assigned by Chinese authorities to the 6th century of the Christian era, more than eight hundred years prior to the discovery of Gutenberg. Through all the vicissitudes from the time of "the burning of the books" by the first emperor of united China, to the war against learning carried on by the present insurgents, literature has flourished in the "middle kingdom," in which it has in part taken the place of religion. The literature of China has always been more akin to that of modern Europe than that of any other Asiatic country. The Chinese have plays, which are a kind of composition unknown to the Arabs and Persians; they have novels and newspapers; they publish criminal trials; they circulate gratuitously religious and temperance tracts of their own. In regard to libraries their state is somewhat problematical. M. Abel Rémusat, in many respects a most judicious and critical writer, tells us in one of his Essays, that an Emperor of China ordered the publication of a select collection of the Chinese classics in 186,000 volumes.

A native Chinese, who was asked in the present year (1860), at the British Museum, what was the largest library in China, said that he had never been to Peking, but that at Hang-chew he had seen one of 6,000,000 volumes; an excellent library to receive the gigantic edition of the Chinese classics. Nothing can be more different from these extraordinary statements, than those of other Chinese scholars and travellers. There is in the British Museum, as in other European libraries, a catalogue printed in China in 1790, of the library of the Emperor Kien Lung, the same who received Lord Macartney. M. Bazin, who published an analysis of this catalogue in the Paris 'Journal Asiatique' for 1850, states that he found it only contained 10,500 distinct works, including, it may be observed, 303 of the nature of encyclopædias, some of which were of large extent. The library did not contain any work in the common and familiar language of China, and all plays, novels, and works of light literature were thus excluded. Rémusat himself, in a subsequent work to that in which he mentioned the edition of the classics, fixed the number of volumes in the largest Chinese library at 300,000, and his first statement respecting the classics is so obviously the fruit of some confusion between "volumes" and "books" or "chapters," that it is surprising other Chinese scholars should have repeated it without suspicion. It is evident that large libraries are rare in China. Europeans who have spent nearly twenty years in the country, and seen more than one of its large cities, report that they never happened to see an extensive collection of books. Collections of ancient porcelain vases are numerous in China, but not collections of ancient volumes. Dr. Schott, in his Survey of Chinese Literature, in the Transactions of the Berlin Academy, quotes the existence of a Chinese printed book at St. Petersburg with the date 1419, as a phenomenon, and observes that it shows the opinion to be erroneous, that a Chinese book can hardly last longer than three centuries on account of the thickness of the paper. The white ants are also great enemies of Chinese literature. In fact, in the libraries of Chinese temples, founded by the Emperor Kang He, who reigned from 1661 to 1722, it is reported by European observers, that many of the books are now illegible from decay, and it is far from improbable that some of the Chinese books presented to the Bodleian, by Archbishop Laud, soon after its foundation in 1602, may be of older date than any to be readily met with in China itself.

Chinese libraries are more numerous in Europe than Russian libraries. There is a fine one at Paris, containing many volumes presented to Louis XIV. by the then reigning Emperor of China; there is one at St. Petersburg, one at Berlin, one at Vienna, and several in London. There is a collection at the East India House, Sir George Staunton's collection in the library of the Royal Asiatic Society, Dr. Morrison the lexicographer's collection at University College, and Dr. Morrison the younger's collection united to Mr. Hull's and several others, at the British Museum. The Museum collection, to which the presentation of Dr. Morrison the younger's library by the British government, added 11,500 volumes at once, is probably of not less than 20,000 volumes, and is scarcely inferior in numbers to any other in Europe.

The nations which are under the influence of Chinese civilisation are all cultivators of printing. The literature of the Manchoo-Tartars, who are intellectually subject to China, though they hold the position of its conquerors, is devoid of interest, as consisting almost entirely of servile translations from Chinese. The Japanese books are not translations from the Chinese, but in most cases Chinese books with Japanese notes and explanations, mixed up in such a state of confusion that the accounts which recent travellers give us of the superiority of the Japanese to the Chinese in point of sagacity and ingenuity, appear to require confirmation before they can be admitted in matters of literature. Siebold, who enjoyed unusual opportunities of observation, stated that libraries are numerous in Japan, and that those both of the secular and the ecclesiastical empire were extensive, but declined giving any opinion as to the numbers which Balbi assumed to be about 150,000 volumes in each. If Siebold's statement were well-founded, that "from five to eight thousand" small volumes, maps, &c. were annually published in the Japanese cities, this estimate has nothing improbable.

Of Manchoo-Tartar books the largest collections in Europe are at

Paris, that language having been a peculiar favourite of the French missionaries; and there is a small collection in the British Museum. The largest assemblage of Japanese books at present in Europe is that at Leyden, brought by Siebold from Japan; but there are others at Vienna and Paris, and a few volumes, probably soon to be augmented, in our own national library.

After leaving China and Japan, it is necessary, in order to find another Asiatic nation, the main body of whose literature exists in print, to pass to the western extremity of Asia, and for the chief seat of its printing-presses to look still further westward in Europe. It is from the island-convent of St. Lazzaro, near Venice, that the chief supply of books is sent forth to the Armenians, the "Jews of Christendom." The same order of literary monks as flourishes at Venice, the Mechitarists, have now founded branch establishments in Vienna and Paris, at which the press is in full activity. They issue not only editions of the ancient Armenian historians, Moses of Chorene and others, but translations of the most popular and useful works from the European languages—Rollin's 'History' and Büsching's 'Geography,' the 'Paradise Lost' and the 'Night Thoughts,' 'Robinson Crusoe' and 'Uncle Tom's Cabin.' In some antagonism to the Roman Catholic Armenians of Venice, who are attached to ancient Armenian, the American missionaries at Smyrna and elsewhere support Protestantism in modern Armenian; and a few books in the language find their way from the press at Calcutta. Of the Venetian publications, there are probably sets in many European libraries, and the Museum has one which is believed to be complete in all but translations, and includes a large selection of these.

The literature of Sanscrit, the ancient language of India, was first made known beyond its ancestral precincts by the researches of Englishmen. The names of Wilkins, Colebrooke, and Wilson, will always receive the veneration of scholars for their inestimable labours as pioneers in a field of study so ancient in one sense, so novel in another. Scarcely half a century has elapsed since the publication of Wilkins's Grammar, and the discovery of the Sanscrit language has changed the basis of philology. A language which eighty years ago was not known to a single European, now counts its professors and students at Oxford and Berlin. Active however as the press has been, both in India and Europe, to reproduce some of the chief productions of Sanscrit literature, the main body of that literature must still be sought not in libraries of printed books, but of manuscripts. There are now collections of some value at Berlin and Oxford, and even at Copenhagen and Paris, but the collection bequeathed by Colebrooke to the East India House at London, is the finest in Europe, and has been a magnet of attraction to Sanscrit scholars, similar to that presented to Hebrew scholars by the Oppenheimer collection at the Bodleian. The Sanscrit manuscripts at the Museum are less than 130, at the East India House more, it is believed, than 3000 volumes, and each volume there, on an average, contains four or five tracts. The best continental scholars are of opinion that without access to that collection, the study of Sanscrit literature cannot be satisfactorily pursued. The recent abolition of the East India Company has made the fate of their library a question for decision, and it is probable that most scholars would wish to see it deposited in the British Museum, were it not that the regulations of the Museum prevent the manuscripts from being taken from within its walls, while the regulations of the East India library are in that respect more liberal than those of any other English establishment.

The languages of India, after the Sanscrit, more than twenty in number, have, except the Hindustanee, little of literary interest, as in most cases they contain hardly anything but translations, whether of works from other oriental languages by natives, or of the Bible by missionaries, or of medical and scientific works by other Europeans, anxious to improve the native mind. Slender as the individual importance of these productions may be, it is still wonderful that so little attempt appears to have been made to collect them, either in India or England; for in the first place they are certain to have some kind of philological value, and in the second they are memorials of one of the most singular phases of society that has ever existed. The English student of one of the languages, with a view of qualifying himself for office in India, might be materially benefited by finding assembled here a good collection of its literature. The best of the kind in London are at the Royal Asiatic Society and at the East India House; but much still remains to be done.

The languages of the Eastern Archipelago, the Javanese, the Bugis, and others, and the omnipresent Malay, present points of interest; and since the time when Sir Stamford Raffles as governor of Java made such vigorous inroads into the realm of ignorance, the Dutch have awakened to wipe away that reproach which was formerly made to them of neglecting studies to which they alone had easy access. Within the last twenty years the Dutch scholars have cultivated the languages of the Archipelago with equal zeal and success, and deserve for their exertions in this matter, the thanks of literary Europe. Of course it is in the Dutch libraries that manuscripts of them are to be found in the greatest abundance; but in the British Museum there is an admirable collection, made by Mr. Crawford, amounting to about 150, and there are also the collections of Marsden at King's College, and of Leyden at the East India House.

All the Mohammedan world, however, in India, in the Eastern

Archipelago and elsewhere, looks for its treasures of literature to one of what are emphatically called "the three languages"—the three great idioms of Western Asia and of Northern Africa—the Arabic, Persian, and Turkish. The literature of the Arabic—of the language which was once not only that of Mecca and Cairo and Fez, but of Cordova and Granada, is now fallen from its high estate. The Mohammedans are paying the penalty of that obstinate aversion to printing, which might almost be considered a part of their religion. The process as practised in China, was described by a Persian historian, who was contemporary with the Crusades; but the description of printing by Rashid-ed-din, remained itself in manuscript till printed at Paris in the 19th century. The art was introduced into Spain more than twenty years before Boabdil was driven forth from Granada; but the first book printed in that city was two years after his expulsion. For centuries after, in Mohammedan countries, the art was contemptuously left to Jews and Christians. The increasing preponderance of the Franks has at last brought about some change, and Arabic books are now printed at Constantinople, at Boulak, near Cairo, at Algiers, and in India. While the French at Algiers print much of the old Arabic literature, the Mohammedans at Boulak chiefly issue translations from the French, of treatises on tactics, mathematics, and medicine. Of Arabic libraries the chief are in Cairo; but there and elsewhere the Arabic libraries of the present day represent the literature of classic Arabic, as the monastic libraries of the middle ages represented the classic literature of Greece and Rome. The Arabic historian, Ibn Aby Tay, affirms, as M. Quatremère tells us, that in the old library of Cairo there were 1200 copies of the history of El-Tabari, a statement that reminds the modern English reader of the 2000 or 3000 copies of Macaulay's History, and M'Clintock's Voyage, in Mudie's circulating library. Every copy of the Arabic of El-Tabari had disappeared and the book was only known in its Persian translation, till a portion of the Arabic was recently discovered in Europe. A similar history will have to be told of many an Arabic classic, which now probably only exists in the great libraries of the Franks. At Paris, at Leyden, at Oxford, at St. Petersburg, and at Vienna, there are large collections, and that at the British Museum is of considerable importance. Sims's useful 'Handbook to the Museum' gives the number of manuscripts as 1060.

While Arabic is to the Mohammedan what Latin is to the Catholic nations, the more easy and familiar Persian takes rather the place of French, and was long to India what the French was to Germany. In the library of Tippoo Sahib, which was chiefly composed of that taken by his father Hyder Ali by force of arms from the Nabob of Cheetore, it was found upon its transference to the East India House, after the fall of Seringapatam that the number of Arabic and Persian works was nearly 2000, and a few works in Hindustanee and other languages completed the library. Stewart, who published the catalogue, expressed his surprise at the number of the volumes; but the library of the king of Oude, which was catalogued by Dr. Sprenger in 1848 at Lucknow, was far superior in numbers though inferior in condition, being devoured by rats and white ants. At Lucknow, the invention of Senefelder had found more favour in Oriental eyes than the invention of Gutenberg. Twelve lithographic presses were at work in the town before some arbitrary caprice of the king of Oude put a check on their activity. More Persian books have been printed and lithographed in India than in Persia itself, where a printing press has however been established in Teheran, which issues a newspaper. Of the three editions of the greatest of Persian poets, Ferdusi, two were printed at Calcutta by Englishmen, and the other at Paris by a German; but most of the treasures of Persian literature are still to be sought in manuscript. Fine libraries of Persian are to be found at Paris, at St. Petersburg (where the collection of oriental manuscripts in the library of the Academy is supposed to be the finest in Europe out of Paris), and at Leyden, Oxford, and London. Tippoo Sahib's library is now in the East India House, and the number of Persian manuscripts at the Museum is given as 1082.

The Turkish language, though far from being of such general literary importance as Arabic and Persian, is abundant in poets, and rich in historians, whose narratives are more generally interesting as describing the Turkish collisions with the more civilised nations whom they unhappily conquered. Its relative importance is well represented by its numbers in the British Museum, in which it counts less than three hundred manuscripts, while Arabic and Persian are, as we have seen, each over a thousand. Printing was partially established in Constantinople at the commencement of the 18th century, and after a long interval of interruption, again in the 19th. The libraries at Constantinople appear to represent the extreme of decentralisation. There are no less than forty of them, and the number of books in each varies according to Von Hammer, from 2000 to 2500, so that the aggregate number of volumes is about 100,000, of which of course the greater part are not only duplicates but triplicates and endless repetitions. Zenker in his 'Bibliotheca Orientalis,' published at Leipzig in 1846, aims at giving a catalogue of all the books in the Arabic, Persian, and Turkish languages, printed either in Europe or Asia, and, even including translations, the number of which he has succeeded in collecting notices is only 1859.

In our literary journey round the world we have been compelled to pass almost insensibly from printed books to manuscripts. Those

who would make a general survey of the published literature of the living world four centuries after the invention of printing, must still extend their view beyond the circle of printed books. This state of things furnishes an additional reason for the arrangement which has been so generally adopted in libraries, of either keeping the manuscript and printed books together if the collection is small, or merely dividing them if the collection is large, into two separate departments kept in the same building.

Some of the most ancient contents of manuscript libraries are among the most recently discovered. The 19th century has already distinguished itself beyond all preceding centuries by its success in making the boundaries of the past recede. While geologists claim to delve into the early history of the earth, the archaeologists of art have unearthed the sculptures and paintings of Egypt and Assyria, and the archaeologists of literature have decyphered Egyptian hieroglyphics and arrow-headed inscriptions. Amid the treasures of the British Museum are 206 hieroglyphical manuscripts on Egyptian papyrus, and what has been called the "library of clay" of the kings of Assyria, disinterred from under pyramids and from buried palaces. In the saloons of Great Russell Street there is now lodged a mass of inscribed earthen cylinders in the arrow-headed character, from which Rawlinson and Norris hope to decipher chronicles and leases, religious books, and grammars. Less ancient indeed than these, but still of very remote antiquity, are the Syrian manuscripts, acquired between 1841 and 1847, from the monasteries of the desert of Nitria, about 1000 in number, and ranging in date from A.D. 411 to A.D. 1292.

The ancient manuscripts of the languages of Greece and Rome in their classical periods have been the ornament of libraries from the time of the revival of literature to the present. They have served their most important purpose by aiding scholars to form a standard text of classical authors whose works, once only existing in perhaps two or three copies, have now passed through innumerable editions, and are found wherever literature is known. It has been remarked that the purity and intelligibility of an author's text are generally in exact proportion to the number of ancient copies of his writings that have been discovered and collated. The manuscripts themselves remained after this use had been made of them, interesting monuments of the past, still more venerable than the earliest editions of printed authors, but regarded as having in a measure "done their work" until the 19th century, threw a new interest over the contents of old libraries, which it was now seen, might like mineral districts contain treasures beneath superior to those on the surface. A fragment of the Roman historian Licinianus has thus been recovered by the two Drs. Pertz, father and son, from a manuscript in the British Museum. Almost all Greek classical manuscripts now in existence are in public libraries, where they are open to collation, and free to be used for the purposes of learning; but there are still a few in situations, such as the conventual libraries of Mount Athos, where they are not easily accessible to the world of editors, and where their possessors are not qualified to use them to advantage. It has been proposed to apply to them the new process of photography for the purpose of reproducing exact facsimiles for the principal libraries of Europe; where they might then be used for the collation of texts with as much confidence as if the originals had been transferred there. A Russian photographer contributed to the exhibition of the Photographic Society in London, some admirable specimens of a reproduction of several pages of a "codex" of Strabo at Mount Athos. The introduction of the new art is probably destined to work a revolution in collections of ancient manuscripts, but it is not yet satisfactorily ascertained that copies can be allowed to be taken without risk of injury to the original. When this obstacle is got over, as there is reason to hope that in a few years it will be, every library of the first rank will probably aim at having facsimiles of the leading manuscripts of the world.

Manuscripts of the middle ages—considering the middle ages to terminate with the invention of printing—are still existing in large numbers unprinted, not only in public libraries, but in private hands. It is probable that a hundred years hence the students of European literature will have much better means at command than ourselves, to take a comprehensive view of the literature of Europe during the earlier part of this "Yearthousand,"—to use a Germanism which is in many respects preferable to "Millennium." The proper use of the treasures of manuscript libraries seems at last likely to be made—by leaving them in manuscript no longer. The French are for the first time publishing their early epics, their long neglected 'Chansons de Geste,' their collections of national songs, their monuments of early language. The Spaniards have printed their 'Cancionero de Baena,' from a manuscript which they were obliged to borrow from Paris, where it is now in possession of the Imperial Library, which had acquired it at a sale in London. In England we are much in arrears. A few years ago it was announced that a society had for the first time taken it in hand to publish a complete edition of the works of King Alfred, on occasion of the thousandth anniversary of his birth, and the undertaking has not been carried out. Under the auspices of the Master of the Rolls, a number of our early historians are now, for the first time, being given to the public. The numerous publishing societies, with the Roxburghe Club, and its more liberal and large-hearted imitators, the Scottish Clubs at their head, have done much

in the same good cause. The British Museum has been the principal mine in which these labourers have worked, and the same collection has also been explored by missionaries of literature sent by the governments of France and Belgium. These have declared that the Museum contained wealth they had not expected in ancient French manuscript literature, while Dr. Pertz, of Berlin, has gone so far as to give his opinion that "if things continue in their present course, every manuscript in Europe, that is not locked up in fiscal collections, or does not become so, will, in the course of another century, become the property of the British Museum." It is not easy, however, to be confident of the accuracy of a prediction so desirable to be accomplished, for in England itself there have been forming in the present generation, two collections of manuscripts in private hands—those of Lord Ashburnham and Sir Thomas Phillipps, of Middlehill—each of which has absorbed more than that of the Museum in the same period of time.

One of the most interesting portions of manuscript collections consists in the illustrated works of the times anterior to printing—the illuminated manuscripts. The illuminations are often the most valuable memorials of the costume and the domestic manners of the period in which they were executed, apart from their merit as works of art, which are sometimes of no mean order. A collection of works of this kind, which have belonged to distinguished personages—for the more valuable specimens almost always bear traces of the parties for whom they were executed, or to whom they successively belonged—presents a union of interest singularly attractive. The Museum is very rich in treasures of this kind. An account of some of the most conspicuous may be found in Waagen's 'Art and Artists in England.'

The state papers and documents of modern times form some of the most interesting portions of those manuscript collections the materials of which are contemporaneous with printing. It has always been the aim of governments to shroud at least some of these documents in secrecy for a time, but their wish has often been remarkably baffled. The most valuable portion of the Cottonian library consisted of documents of historical importance so near to the collector's own period that it is no wonder the government looked on them with jealousy. King James I. found in private hands some of the most deeply interesting papers relating to the captivity and execution of his mother, and his own conduct on the occasion. There seems no adequate reason why, as these Cottonian state papers have now been for more than a hundred years in the British Museum, and nothing but good has resulted from it, the whole of the documents of the State Paper Office, of that and anterior dates, should not, as has often been suggested, be made equally accessible, either by transferring them thither or by adopting at the office the same regulations as at the Museum. Even those of later dates, down at least as far as the revolution of 1688, might, apparently with advantage, be considered to have passed from the domain of statesmanship to that of history. The 'Calendars' of these State Papers, which are now being issued from the press, will, in all probability, place the advisability of this measure in a stronger light, by showing of how many transactions a portion of the evidence is to be found at the Museum and a portion at the State Paper Office. These 'Calendars' were in some measure anticipated by similar lists published in America, of documents relating to the history of some of the states when colonies of Great Britain, which were made by Americans—Henry Stevens and others—at the office, by permission of the Secretary of State. A similar liberality has been exercised by foreign governments towards our own, in allowing copies of documents in foreign libraries, which are illustrative of English history, to be taken and deposited in the British Museum. Such are a collection of fifty volumes of papers from the Vatican, and a number of others from the Hague, which were much used by Macaulay in his 'History of England.' It has been suggested that the more ancient portion of the English legal records, which are to be assembled at the Record Office now building in Fetter Lane, and the ancient wills at Doctors' Commons, no longer of probable use for any but literary purposes, should be deposited at the British Museum, whence they can easily be reclaimed if any unexpected occasion for their legal use should arise. The extent of these, however, is so great, and their general interest so little, that the question does not stand upon the same footing with that regarding the State Papers. It may still be advisable to make a difference between libraries and archives. The collection of the archives of Venice, which was formed by the Emperor Francis I., of Austria, is said by Balbi, to be composed of 1890 different collections, to occupy 298 chambers, saloons, and corridors, and to extend to 8,664,709 volumes, the matter of which would occupy about three millions and a half of ordinary octavos. Our own records, though not so voluminous as these, are still said to be some of the completest in Europe. Such vast collections of matter may well demand an edifice and a staff of officers for themselves.

Even in times when printing becomes more general in its use than it is now, or has ever been, there will still be an occasion for forming libraries of some contemporary manuscripts. Collections of autographs will always be eagerly sought after: the original manuscripts of the compositions of great authors will always command a deep and respectful interest. "Breathes there the man with soul so dead" who can look with indifference on the original manuscript of Walter Scott's 'Kenilworth,' or Burns's sketch of his own life, or the deed by which

Milton sold 'Paradise Lost,' or the autograph of Shakspeare, or the will of Mary Queen of Scots, or the lines that Lady Jane Grey wrote in the prayer-book she had with her on the scaffold? All these are in the Museum; but it has no large collection of recent autographs, such as is now possessed by several continental libraries, and would be of frequent use for the verification of the authenticity of signatures. The diaries of Byron, of Walter Scott, and of Moore—books such as these should also be secured, if possible, for our national library, for, by their remaining in private hands, an occasion is lost for much innocent and ennobling gratification of the public. A library of printed books resembles a collection of engravings, a library of manuscripts resembles a collection of paintings; and as the one cannot aspire to the completeness of the other, it should aim at making up for the deficiency by the high excellence of some of its constituents. Such books as have been mentioned would be equivalent to a fine Raffaele or Murillo.

A great library of printed books and manuscripts will thus, if carried out on a scale worthy of a great nation, comprise specimens of every kind of literature that the world has produced, from the earliest that the tooth of time has spared to the last and least in date—from the library of the kings of Assyria to the 'Clerkenwell News.' A national collection of this kind is the greatest of ornaments to a capital, and yet is of still greater use than ornament. It is a boon to the casual visitor, still more to the constant resident, for its treasures are inexhaustible in the limits of a hundred lives.

The rules which are applicable to the collection and management of a large public library are certainly the same in principle which are applicable to those of a small one. The difference is only in the scale on which they are to be applied; but the effect of this difference is in some things enormous. In the case of a large library, not only must everything be done more extensively, but many things more minutely. Errors and oversights which are of small consequence in a small catalogue, for instance, are not only more difficult to avoid in a large one, but when they are not avoided they are more misleading and more confusing.

It has been supposed that some of these difficulties may be got over by treating a large library as an amalgamation of small ones. It has been suggested, for instance, that in so immense a collection as the British Museum there should be librarians for separate parts of it—one for the theology, another for the law, a third for natural history, a fourth for medicine, a fifth for mathematics, and others for other branches. To this it has been answered that, practically, another kind of division is not only preferable, but in some cases imperative. There are books on medicine, for instance, in the Museum not only in English, Latin, French, and German, which are the most ordinary languages for the subject, but in Spanish, Danish, Russian, Chinese, &c. A medical librarian, therefore, not acquainted with Russian and Chinese, would not be able to class or to catalogue the whole of the books in his department. On the other hand, a Russian scholar not acquainted with medicine or mathematics would meet with no difficulty, if of ordinary intelligence, in classing and cataloguing a Russian medical or mathematical volume.

The first requisite therefore for dealing efficiently with a book is to be able to read the title-page,—and often a great deal more than the title-page. In fact, at the Museum, though the different assistants of the Printed Book department are all officially reported as engaged without distinction in "assisting the keeper of the printed books," it has been found in practice necessary to have one to catalogue Hebrew and another to catalogue Chinese; and books in certain other languages, Slavonic or Oriental, only go to particular persons. As there are more than twenty cataloguers, a division can easily be made; but the difficulty recurs in the case of operations which are confided to one or two persons only. The books to be sent to the binder, for instance, are sent by one assistant, and the letterings to each book are to be in the language of that book. The course necessarily taken is, for the assistant to write the letterings in as many languages as he can, and to apply in cases of difficulty to those of his colleagues who can assist him. The binder himself is often in a perplexity, and obliged to ask for information; for, it must be remembered that the printed directions to the binder given in books at the Museum are couched, of course, in the language of the book—Welsh or Wallachian, as the case may be. As the library is now arranged in different classes, and each book is placed according to its subject, it is of course necessary, also, for those who place them to read at least the title of each, or to have the title translated for them. In short, in all the operations of a library, from first to last, and more especially of a large library, the question of language is continually recurring,—although, strange to say, in outside speculations on the subject of library management, it appears to be continually overlooked. It may be doubted if Mr. Gladstone, when he recently told the House of Commons, as Chancellor of the Exchequer, that the duties of the assistants in the British Museum were so easy and agreeable, that their salaries might well be proportionably light, remembered at the moment that it was part of those duties to catalogue Sanscrit and Chinese.

In addition to qualifications of this kind, it is especially required in those who are entrusted with the selection of books to be purchased for a large library, that they should have an acquaintance with bibliography in general. The name of no other science has been so misapplied

as this. To call a man a bibliographer because he is well acquainted with the productions of the press of the Alduses and the Elzevirs is as absurd, however frequently done, as it would be to call a man a geographer because he was familiar with the topography of the weald of Kent or the coast of Sussex. Bibliography is the knowledge of the world of books, as geography is the knowledge of the world of sea and land. The ramifications and details of the science are infinite; but it is no more the business of a bibliographer to know every detail of a set of volumes than of a geographer to know every street of a market-town.

When it is determined what books are to be acquired, the method of acquiring them comes next into consideration. The best and most rapid method of increasing a large library has often been said to be the purchase of collections in a mass. There can be no doubt that, if it be determined to form a library of one or two hundred thousand volumes, and a good collection of forty or fifty thousand occurs for sale, it will be expedient to secure it to begin with. There are certain books that may be expected to be found in every considerable collection, and to acquire them by thousands is a saving in point of time to acquiring them one by one. But this very circumstance renders it impossible to proceed in the same way. If a second collection, still more if a third or a fourth, be bought in a mass, there is a certainty of acquiring duplicates, triplicates, and quadruplicates. It is true that in the history of several of the great libraries we find this proceeding recorded as having taken place. The library of Vienna, we are told, was enriched on the decease of its librarian Blotz by the books which had belonged to Blotz, on the decease of his successor Tegnagel by those of Tegnagel, and on the decease of his successor Lambecius by those of Lambecius. It is evident, however, by the mere statement of the facts that they involve a dilemma. Either these acquisitions brought duplicates to the library by wholesale, or else during the lifetime of Blotz, Tegnagel, and Lambecius, the collection of which they were the guardians must have been deficient in the very books which they esteemed worthy of a place in their own libraries, and thus the addition of a valuable set to the imperial collection must have depended, not on the life, but on the death of the librarian. It is, in fact, a strong censure on the composition of any great library, that it should be possible to add a large well-chosen collection to it without adding a mass of duplicates. There may be occasions on which, not to let an opportunity escape, it may be advisable for the possessors of a large library to buy another in a mass, but in that case it will be necessary to sell again immediately most of what has been purchased.

The additions to a large well-chosen library will thus have to be made in detail. This will more particularly be the case with the current literature of the day—a kind of literature which has been perhaps more frequently overlooked in large libraries than any other from the time of the invention of printing downwards. There has been a singularly obstinate delusion, that it might be safely neglected because procurable at any time—a delusion which, much to the advantage of posterity, appears to be giving way. The method of arriving at a knowledge of this literature is easy and obvious. To Germany and its booksellers we are indebted for that simple but invaluable invention, the catalogue of all the new books published at certain intervals, which was first exemplified in the catalogues of the fairs of Frankfort and Leipzig—one of the earliest forms of periodical publication, the first of these lists being 101 years antecedent to the 'Journal des Savans,' which was the first review. Separate editions of them were apparently issued for different countries; for we have seen in the British Museum a Leipzig catalogue for part of 1623, in which a long list of English books is given, which does not occur in the ordinary German copies. No other periodical catalogue of English books so early as this is known; Maunsell's, which preceded it, being not of a periodical character. It is the earliest member of the family which was represented by 'Clavell's Lists' in the time of Charles II., and now by 'Bent's Advertiser' and the 'Publishers' Circular.' Publications of the same nature are now issued in nearly every European country; and by inspecting the whole, and giving orders from each, it is practicable for any library provided with the indispensable requisite, liberal funds, to collect under one roof in an unbroken flow the whole mass of current European and American publications of value, without any other agency than that of the ordinary book-trade.

Books published for sale may be divided into those which are on sale by the publisher, and those which are "out of print," according to the technical phrase; that is, into those which are procurable at once if an order is given to a bookseller, and those which can only be acquired when an opportunity occurs, at sales by auction or otherwise. The purchase of a book when it is on sale by the publisher is the simplest method of acquiring it, but it is supposed not to be the most economical, because by waiting it may generally be obtained at a lower price. In many cases, however, it is the most economical also; for if there be a demand for a book, and it becomes out of print, the price of it immediately ascends, and sometimes to an extravagant height. In England, and still more in America, a book passes so soon out of the hands of its publisher,—such violent measures are sometimes adopted to get rid of it in the way of a "remainder,"—that those who do not buy it on its first appearance may often afterwards inquire for it in vain. In Germany a different and less hurried system prevails: the stock of a

bookseller often passes from generation to generation, from century to century, and some books may be ordered from the publisher in sheets a hundred and fifty years after their first appearance.

The great majority of books are of course those not procurable at first hand, those which are only accessible through the medium of the second-hand bookseller—in Germany he bears the more respectful name of "antiquarian" bookseller—or the sale by auction. It is a question of some importance whether the best method of acquiring these is through the bookseller or the auctioneer. The first method is obviously the most simple, and to the purchaser by far the most convenient. The price of the book—a most necessary element in the decision on its purchase—is known beforehand; the book is also generally sold with a guarantee of its completeness. On the other hand, at a sale it is necessary for the intending purchaser to decide what price he will go to, a decision which cannot in many cases be arrived at without considerable trouble, and which is after all almost certain to be repented if the book happen to be sold a little over. It is not uncommon, also, to sell books at auctions with all faults or errors of description; and, in any case, to return a book purchased at an auction is a more circuitous and troublesome process than to return one purchased of a bookseller. It is also exceedingly inconvenient to attend or procure attendance at the time and place of sale. Under all these drawbacks, it is somewhat surprising that purchasing books at sales should be so popular, that it is becoming a common remark among booksellers that books which they have long offered in vain in their published catalogues go off at once at higher prices when a copy occurs at an auction. It might have been accounted for more easily during the period of bibliomania at the beginning of the present century, when it was customary for amateurs and collectors to attend in person at sales, and the Valdarfer Boccaccio, for instance, was contended for by the Marquis of Blandford, Earl Spencer, and others, in the auction-room. The scene was so dramatic, and the excitement so contagious, that the contest for an old folio might arouse the passions as well as the chase after a fox. The case is altered at present, when the biddings are made by booksellers or their commissioners, and the prices which purchasers are to give are finally decided upon beforehand, in the cool of the study instead of the heat of the auction-room. Still the highest prices which are now obtained for books are generally given at auctions, and the lowest prices at which books are sold are also taken at auctions. But for this latter circumstance—as the innovation has now been attempted of publishing a book by auction—there would be some danger that the trade of a bookseller behind the counter would cease. Both bookseller and auctioneer still continue, and if either is destined to become extinct, it is to be hoped, for the sake of purchasers, it may be the auctioneer.

A proposal has recently found favour in the eyes of some for acquiring books for public libraries by means of exchange. To substitute exchange for purchase is simply a return to barter, which is not considered advisable by political economists in other cases, and of which no peculiar benefits have been pointed out in connection with the trade in books. The advocates of the measure appear, in fact, to forget the advantages of a circulating medium. If, as they allege, some libraries are encumbered with duplicates, and at the same time labour under a deficiency of funds for purchases, it would seem obvious that a simple method of escaping from the double difficulty would be to sell the duplicates, and with the proceeds purchase what was wanted to as great an extent as the funds allowed. If instead of selling and buying, librarians put themselves into the hands of an agent to exchange their books for other books in the possession of some other library, they depend in a great measure on the agent's sagacity and honesty, and unless the books in the possession of both the contracting parties happen to be exactly equal in value, there must after all be some money exchanged; as, indeed, in all cases, some money must pass in recompense of the services of the agent. The plan has been tried, at the suggestion of the agent, M. Vattermare, between France and some of the States of America, and some of the American states have expressed themselves satisfied: but this measure of success in the experiment does not seem likely to lead to its wider adoption.

Public libraries of great importance have been endowed in almost every country with the legal right of demanding gratuitous copies of every book published in the state to which they belong. The history of the right and its limitations in various countries is treated of at some length in Edwards's 'Memoirs on Libraries.' From the earlier part of this century up to 1836, eleven copies of every book published in England, Scotland, or Ireland, had to be delivered to different public libraries in the three countries; but by an act of parliament of that year the number was reduced to five, of which that to the British Museum was to be delivered at that institution without being demanded, under penalty in case of neglect of a fine of five pounds. The complaints against the "copy-tax," as it has been called, have often been very loud, though the imposition is extremely moderate when compared with the tax on patents, to which it bears a close analogy. It may be doubted if any superior method could be pointed out, to form a complete collection of the products of the press. It has been said that acquirement by purchase would be as much more effectual as it would be more agreeable to all parties. But is this well established? The publisher of a local halfpenny newspaper is seldom found to keep a complete set of his own journal, the trouble of doing so is not com-

pensated to him by the price. There is much more chance of his attention being aroused by the danger of being fined five pounds than that of losing a halfpenny. The 'Bibliographie de la France,' published weekly at Paris, is a record of the copies of books sent in obedience to the law, to the office for receiving the legal deposits. It is extremely common when orders are given to booksellers in Paris for some of the smaller and cheaper works recorded in it, to receive for an answer that it is impossible to procure them, that publishers in the provinces will not take the trouble to send them, or that printers in Paris will not take the trouble of looking them up. Those, therefore, who are anxious to see preserved one copy at least of the "fugitive literature" of our times, will not regret that the legislature has supplied a powerful motive for publishers to attend to the supply of the national library.

A somewhat new light has been thrown upon the matter by recent transactions in America. The copy-tax was partly abolished last year in the United States, on the petition, not of the publishers, who are usually spoken of in England as the aggrieved parties, but of the librarians, on whom devolved the trouble of collecting it. In February, 1859, by an Act of Congress, it was determined that for the future one copy only instead of three of each book published in the United States should be required of the publishers, to be deposited in the "department of the interior," and that the Smithsonian Institution should be exonerated from the duty of receiving and preserving copies, which was considered a burthen rather than a benefit. The conduct of Sir Thomas Bodley has thus been selected for imitation by American librarians in the very point in which it was a warning instead of an example.

When books have entered a public library, one of the first operations usually performed on them is to mark them as the property of the institution by a stamp. The stamp in many cases bears the name of the institution only; it is now, by a simple but ingenious contrivance, made at the British Museum to bear also the date on which the stamp is affixed. The uses of this are manifold. It is sometimes of consequence, even in a legal point of view, to ascertain the exact date on which a book entered the Museum—it is a proof that on that day, if not before, the book was published. In the old Thomason collection of tracts, the collector noted on the title-page of each pamphlet the day on which he obtained it; and Mr. Masson, the biographer of Milton, will thus have it in his power to ascertain the exact date of issue of several of Milton's publications, some of which were given by the poet himself to the collector. A similar end is contributed to by a regulation now adopted with regard to the Museum bindings. The cover of every pamphlet, and of every number of a magazine, is bound along with it. The 'English Cyclopædia,' which the reader now has before him, is issued in monthly numbers with covers: when the volume is bound the covers are generally removed by the binder and destroyed. There are at the British Museum more copies than one of this Cyclopædia, and in that which is obtained by the copyright law, the covers are bound up with the text, and not at the end of each volume, but at the end of each number, so that in the bound volume the light-brown covers meet the eye at certain intervals in the midst of the white pages. An eminent Spanish bibliographer, who was visiting the Museum a few years ago, complained of the unsightliness of this practice in regard to some modern Spanish books he was examining, and it was pointed out to him that the covers in that case contained a portion of information which occurred nowhere else, and was thus preserved for perpetual use. Struck with the circumstance which he had overlooked before, he was silent for a minute, and then declared that on his return home he would take care to adopt the plan in his own books, and mention it elsewhere, for that otherwise it was likely that the British Museum would in a few years contain unique copies of most of the books which it imported from Spain.

The question of the catalogues of public libraries is one that has been much debated of late years both in England and France. A portion was issued in 1841, of an alphabetical catalogue of the library of the British Museum, in a folio volume, comprising the letter A; and a portion of a classed catalogue of the Imperial Library of Paris has been published since 1855, in six quarto volumes, comprising the history of France, and a part of the division of Medicine. These are the two largest libraries of which it has been attempted to publish a catalogue, and that of the Museum has not been carried further in print, though it is now advancing rapidly in manuscript, and will probably, in the course of 1862, be brought to a conclusion, that is, it will then be completed, in manuscript, on a level with the time. The immense acquisitions of the library throughout the period during which it has been carried on, have rendered it necessary to catalogue almost 400,000 volumes which were not in the Museum at the time that a commencement was made of printing. When the catalogue of more than 600,000 volumes is completed in manuscript, the question will again present itself whether it is to remain in manuscript or to be printed; and if printed, whether in a classed or alphabetical arrangement.

It seems to be generally assumed that the title-slip, or title-card, for a book, when once written, is only available for some particular form of catalogue—that it must necessarily be arranged in the order indicated by the heading, and no other. A moment's examination of the question will show that this opinion is by no means well founded.

Take, for instance, the following—a specimen of one of the Museum "title-slips," or written "billets," describing a book:—

598 i. Lingard (John).
History of England. 9 vols.
London, 1819-40. 4to.

The mysterious "598 i." to the left is what is called the "press-mark,"—that is, the indication of the locality in which the book stands: which, in this instance, is in the press or book-case marked 598, and in the ninth shelf from the top of that press, the successive shelves being marked by the letters of the alphabet, a, b, c, &c., in regular order. The use for which this title-slip was originally written was that it might be placed in the alphabetical order of the author's name, "Lingard," and thus form a component part of the great alphabetical catalogue of the authors' names. But in addition to such a catalogue as this, the interior management of a large library imperatively requires another, which is generally termed a hand-catalogue, but might more appropriately be called a shelf-catalogue—a list which indicates all the books of the library in the order in which they stand on the shelves, so that if a volume be missing there may be the means of ascertaining what it is. In most cases this hand-catalogue is made up quite separately, and to make it is a serious business. At the Museum, where four identical copies of every title-slip are now produced simultaneously by writing with a sort of stylus on prepared paper, it was proposed by one of the officers that one of these copies should be arranged in the order, not of the author's name, but of the press-marks, by which, *ipso facto*, a shelf-catalogue would at once be produced with the minimum of trouble. Directions were given to do so, and a hand-catalogue was and is produced accordingly without the application of a particle of skilled labour more than is requisite to read the letters and figures. In the recent part of the Museum building, a shelf-catalogue presents another advantage of some moment. As, by an arrangement which will be described a little further on, the books are classed on the shelves, those who consult the shelf-catalogue of the presses which are assigned to the history of Spain, the topography of Switzerland, the science of pneumatics, or any other subject, find assembled the titles of all the books on that subject of recent acquisition which the Museum possesses,—they find, in fact, in the shelf-catalogue, a sort of rough classed catalogue. The success of the new arrangement led the officer who proposed it, Mr. Watts, to suggest, in 1855, a further extension of the principle. The name of a book is often remembered without remembering the name of the author. This is so often the case with regard to plays and novels, that in the catalogues of circulating libraries intended for practical use the name of the book is generally taken by preference. To meet this want, Mr. Watts proposed to arrange a copy of the title-slips in the alphabetical order of the words which immediately follow the author's name. Thus, the 'Rejected Addresses' of Horace and James Smith would be found in one catalogue in the order of the word "Rejected," while in the other they would figure under the name of the Smiths. To search for anything in the present Museum catalogue amid the names of the multitudinous Smiths, is in itself so tedious a task that the book would certainly be in general looked out with much more ease under its own title; and it may be added that as some of the editions were published with the authors' names and some without, the proposed catalogue would have the advantage of assembling them all under 'Rejected Addresses,' an advantage which would be extended to all books in the same semi-anonymous predicament. All 'Histories of England,' all 'Strangers in London,' &c., would be brought together, whatever might be the names of the authors.

A fourth copy of the title might be used to make a fourth catalogue, of a kind analogous to that of early books in Panzer's 'Initia Typographica.' In this catalogue the title-slips would be arranged in the alphabetical order of the places of printing, and those of the same place of printing would be arranged chronologically. To local antiquaries, or to local inquirers of any sort, this would be a material assistance. It might be seen at once without difficulty what books the Museum contained printed at Norwich, or St. Alban's, or Aberdeen, or Belfast; or, to take a wider range, at the Cape of Good Hope, or Madras, or Melbourne. By looking at Pesth, or Lisbon, and a few other sub-divisions, it might be ascertained with ease what were the latest accessions in Hungarian or Portuguese literature. With Paris and London, under which the entries would be excessively numerous, the gain would be great. A reader might trace the gradual progress of printing in London from Wynkyn de Worde onwards; might look up what books were issued in the first year of the Reformation, in that in which Shakspeare came to London, in those of the protectorate of Cromwell, in that of the Revolution! Macaulay would have found in a body all the plays, and the ballads, and the nonjuring divinity, and the political pamphlets, that were poured forth in town in 1688; and then, turning to the volume of Dublin, all the products of that stormy year in Ireland. There is hardly a literary man who would not have some desire of this kind to gratify, and to many it would present ready to their hand a mass of materials on various historical subjects, which they would otherwise scarcely think of looking for. This kind of information is at present inaccessible, except at the expense of tedious research. That valuable but very imperfect book,

Cotton's 'Typographical Gazetteer,' might be at once corrected with ease in a hundred passages. Such would, it is supposed, be the benefits of this new method of making use of the duplicate title-slips of the Museum. If, instead of four copies of the title-slips, there were twenty (which might be cheaply produced by the aid of printing or lithography), other catalogues might be evolved. There might be lists of all the accessions to the Museum, in the order of their arrival. There might also be catalogues of books arranged according to the languages in which they were written, so that those who only sought English books need not turn over page after page of Latin or French titles, and those who sought for German or Russian might at once find what they sought. There might also be special catalogues of particular classes: of English plays, or English novels, or books on vellum, or books with autographs. In short, without any additional trouble as to cataloguing, the mere "shuffling of the cards," or title-slips, the mere different arrangement of them by ordinary hands, might produce a variety of catalogues which would secure to every reader a number of different ways of looking for any particular book or class of books he was in search of.

Were the title-slips thus put in print, kept standing in type, and a catalogue occasionally issued of, for instance, the books added to the Museum which were printed in the years from 1851 to 1860 inclusive, the list thus formed would be of much value. It would be the most copious list of English, Scotch, and Irish books of the period embraced. In the so-called London catalogues much is passed over that is issued in London,—plays and Quakers' books, and Roman Catholic and Swedenborgian and Mormonite literature, reports of charities and societies, catalogues of exhibitions, and numerous other kinds of publications, including of course privately printed books, many of which come to the Museum as presents. In addition to this, there would be a select list of all the principal publications of Europe, from Lisbon to St. Petersburg, and of America, from Montreal to Buenos Ayres. Such a list of about 100,000 volumes published within ten years, would not only be an interesting memorial of the progress of the Museum, but a useful handbook to the lover of bibliography.

The classification of books in a catalogue or in a library is a subject that has often been discussed. To classify in a catalogue is of course an easier task than to classify on shelves; the titles are all of one size, and may be shifted or shuffled at will, but the volumes are sometimes heavy materials, and hard to move, and are of all sizes, from the 'Bijou Almanack,' to the great 'Dutch Atlas' in the British Museum, nearly six feet high. When the learned Lambecius, in the 17th century, arranged the books in the Vienna library according to their subjects, irrespective of size, so that a diminutive duodecimo sometimes stood side by side with an atlas folio, the appearance was so strange, and the quantity of space that was lost was so immense, that the first thing done by his successor Nesselius, was to re-arrange the books according to their sizes. It is often the case in the history of libraries that we find a new librarian carefully reversing all that his predecessor has done, but it does not follow that in all such cases the alteration is an improvement, as it seems to have been in this. The plans for the classification of catalogues have multiplied to such an extent, that at last a classification of the systems is almost necessary. M. Achard in his 'Bibliographie' gives an account of several; the Rev. Mr. Horne in his 'Introduction to Bibliography' follows him, and increases the list; and Mr. Edwards in his 'Memoirs on Libraries,' not only pursues the subject to a still greater extent, but gives a tabular view of thirty-two of the contending systems. Many of these differ only in trifles, and some of them are utterly worthless and beneath discussion. The system which has in its main features been more followed than all the others together, is that which is called the system of the Paris booksellers. On this plan all literature is divided into five sections—Theology, Jurisprudence, Philosophy or the Arts and Sciences, Polite Literature, and History. The division Arts and Sciences is a sort of general receptacle for all which could not find a place in the others: the limits of the remaining four are tolerably well defined, and any great collection of books must always be divisible into them. Many of the other systems aim at changing the order of precedence of these divisions, but it obviously matters little if Theology be placed before or after History, Literature before or after Jurisprudence. It matters little also if the books on the history of France be placed before or after the books on the history of Spain, provided that in a large library the division of books on these two subjects is consistently made, and the books on each are carefully kept together. The really important differences are in apparently minor matters, on the question for instance which divides Francke in his catalogue of the Bübau library from most of his compeers. In a large library there will be numerous histories of the cholera in particular places, in Exeter, in Bologna, in Lisbon, in Linköping, in Moscow. According to Francke's system, all books of history in which a locality is specified, belong to the history of that locality, and thus a narrative of the cholera at Bologna will be put in the same subdivision with a history of painting at Bologna. According to most other arrangements, all histories of the cholera will form part of the division, "Medicine," in itself a subdivision of Arts and Sciences in the system of the Parisian booksellers, and all histories of painting will be classed under the "Fine Arts," another subdivision of Arts and Sciences. The question is a knotty one to resolve in the arrangement of a library on the shelves: in

the arrangement of the entries of a catalogue, it is easiest answered by placing copies of them under several divisions.

The method of arranging books in a library has also been the subject of much consideration. Great importance has been attached to the opinions of Della Santa, a Florentine, who gained a reputation by the original ideas which he promulgated in 1816 in an ingenious pamphlet on the subject of libraries. Della Santa was the first to attack with force of argument the old and favourite notion that it was necessary to accommodate a library, like a picture gallery, with a suite of elegant apartments fit to be shown to strangers; and he proposed instead that a collection of books should be packed as closely as possible in the most convenient proximity attainable to a reading-room, to which alone any attention need be given for mere appearance. He also maintained the proposition that the attempt to arrange books in any kind of scientific order was a "mockery, a delusion, and a snare," and certain to lead to nothing but confusion. His doctrine was that it did not matter in the slightest degree where a book was placed provided it could be found on the instant by means of its press-mark, and that all scientific arrangement should be reserved for the catalogues. The same views have been advanced in a pamphlet in both French and Russian, by M. Sobolshchikov, one of the librarians of St. Petersburg, published in 1859; and it appears that the library of St. Petersburg is arranged, if it may be so called, on this principle of non-arrangement. The books are placed on the shelves without any attempt to class them, and the press-mark is all in all. It has been already explained in another article of this Cyclopædia [BRITISH MUSEUM], that there the attempt to class the library has been made, and is considered to have succeeded. Certain it is that while the books are, by means of the press-marks, found by the attendants without any difficulty, the different classes of books are kept together in scientific order, and that as fast as fresh books on any subject come in, in any quantity, they are placed side by side with their predecessors of the same class. The method which is adopted is to have presses or book-cases of equal size, so that the books in one can be shifted when required into another, and to have the number-marks of the presses loose and removeable, so that when the books are shifted, the number-mark may be removed with them. Thus the books on chess will constantly stand in press 7915, though press 7915 may at one period stand in the north-east wing, and at another period in the south-west. The numbers of the presses are inconsecutive, so that though the presses always stand in the order of sequence, the opportunity is left of inserting between any two of them such additional presses with appropriate numbers as the increase of the library may render requisite. At Berlin, the same freedom of movement and fixedness of marks are aimed at by a different method; instead of the presses it is the books which are numbered with inconsecutive numbers, a plan which is followed at the Museum, in marking the periodical publications, but is found to present many inconveniences which are avoided by the other system. When applied to single books it certainly imposes much more trouble on the librarians, and does not lessen the labour of the attendants who have to find the books by the press-mark. A favourite system in Munich, and many of the continental libraries, is to divide all the books into about forty different sections, such as Ancient History, Jurisprudence, &c., denoted by the letters of the alphabet, single and double, to take the books of each class according to their sizes,—folio, quarto, and octavo, or under, and to arrange them in alphabetical order according to the authors' names or other headings. Thus, if a 'Lingard's England' be wanted in quarto, the librarian goes to the range of quartos in the division History, and finds it in its alphabetical order under the letter L. In such an arrangement volumes with authors' names may be found even without the aid of a press-mark and a catalogue; but in the London Institution in Finsbury Circus, which is mainly arranged on this principle, it was thought some years ago that press-marks might be usefully added.

One of the great differences in the management of libraries consists in the regulations of admission. In foreign public libraries in general admission is given at stated times to all who present themselves, subject to certain rules as to age, dress, and demeanour; in the Chetham library, at Manchester, and in the "Free Libraries" which have been recently established in England, the rule is the same; but in other English institutions, and even at the British Museum, admission is more restricted. At the Museum it is necessary, in order to procure a reading-ticket, to apply for it in writing to the principal librarian, and to send in conjunction with the application a letter of recommendation from a householder. Practically a ticket of admission has for many years past been in the reach of almost every one who chose to take the trouble of applying for it, but some complaints have been made of the illiberality of requiring any ticket at all. Several years ago, in 1836, a suggestion was made by a writer who is now an officer of the Museum, that two distinct reading-rooms should be provided, one open to the public in general, like the galleries of Antiquities and Natural History, the other as before for readers who had received a ticket from the principal librarian. The public reading-room was to be provided with a separate catalogue, to contain every work of use and information, but not works of exceptional value. All those who entered it would thus have access, for instance, to several good editions of the works of Shakspeare, but not to the early quartos of his separate plays,

which are often worth more than their weight in gold. The readers with tickets in the special reading-room would have the same catalogues as at present, and would, as now, be able to have anything they pleased. This plan of two distinct reading-rooms for one library has never been entertained in England, but it was proposed in 1858 in France, by M. Prosper Mérimée, in a report on the imperial library in Paris, and adopted forthwith by the Emperor, who gave orders that it should be carried into effect in the new buildings for that library now in course of erection. The complaint at Paris had been precisely the reverse of that at London. It was, that by indiscriminate admission of the population of Paris it was found that those who wished really to study were placed at a disadvantage—that the tables of the reading-room were often occupied in winter by those who came merely for the sake of warmth, and some of whom might be seen holding a book in their hands bottom upwards. The universally open reading-room would be the novelty at London, the select reading-room will be the novelty at Paris—at least as a part of the regulations, for we can report from personal observation in 1840, that at that time little knots of select readers were admitted to a librarian's table in an inner room. It may be observed that, with all restrictions, some classes of readers are more numerous represented at London than at Paris. There are more ladies, in proportion, in the Museum reading-room, where there are two tables provided for their exclusive accommodation, and where they are also at liberty to take their seats at any other table. At the new public library at Boston, in Massachusetts, attention to the fair sex has been carried still further, as a separate room is provided for them with a hundred seats, while the reading-room for the gentlemen has no more than twice as many.

There has been occasional discussion for many years past in London respecting the advantages of an evening reading-room at the Museum, the evening being undoubtedly the time at which the other literary institutions of London are most frequented. The main objection to it appears to be the risk of conflagration, and it was suggested that the evening reading-room should be in a building entirely separated from the main body of the library, except by a narrow well-guarded fireproof passage, easily to be cut off from communication in case of fire. In the magnificent reading-room in the centre of the Museum, which has since been erected at Mr. Panizzi's suggestion, the light of day is admitted by a range of twenty lofty windows, through which if necessary the light of gas might be admitted at night, the gas being in standards outside, and at some distance from the building. Abroad, the question has been solved without these precautions. The library of St. Gervaise, at Paris, which was rebuilt in 1851, was constructed with an express view to the employment of gas, and the magnificent room which contains it, one of the finest library rooms in the world, is now open in the evening throughout the year. At the library of St. Petersburg the hours have also been extended from ten in the morning to nine in the evening all the year round. In high northern latitudes, to exclude the use of light and fire, as is done in many of the libraries of Italy, would be to limit most materially the utility of such institutions; some alteration in that respect is demanded by the climate; but it seems surprising that, with the great calamity of the conflagration of the Winter Palace before them, the authorities at St. Petersburg should be bold enough to risk the destruction of their immense repository of literature by unnecessary daring. A separate reading-room for the time of artificial light would afford an additional security which it would surely be no idle precaution to take.

The question if books should be lent out from great public libraries is generally decided differently in foreign countries and in England. It is perhaps a consequence of this that "circulating libraries" in their modern sense—that is, shops in which books are lent for hire—are, apparently, an English, or rather a Scottish, invention. In their larger sense they may be traced as far back as the days of St. Jerome, in the 4th century. St. Jerome expressly mentions that St. Pamphilus, presbyter of Cæsarea, who died A.D. 309, made a collection of books amounting to 30,000 volumes, chiefly of a religious character, with the object of lending them out to religiously disposed people to read. "This," says Dr. Adam Clarke, "is, if I mistake not, the first notice we have of a circulating library." There are, however, some traces in Aulus Gellius that it was permitted to borrow books from the public libraries; though probably the usage of having libraries at the public baths, where so many of the people spent their time, and the habit of living in public is common among the ancient as well as modern nations of the south, made it far from a prevalent practice to borrow books to read at home. In the middle ages there are frequent traces in the history of the universities of Bologna and Paris that it was customary for booksellers to lend books for hire to the students, who would otherwise have hardly been able to obtain the requisite number for study. In Busch's 'Handbuch der Erfindungen,' circulating libraries are said to have been originally invented by Dr. Franklin, when a journeyman printer at Boston, in 1720. In 1720, Franklin was a boy of fourteen, and the institution that is meant is doubtless the subscription library established by him at Philadelphia in 1731, which is generally considered as the earliest claimed for Franklin in his Autobiography, though the terms which he uses are consistent with that supposition. The first circulating library in Great Britain is said in the 'Picture of London,' to have been begun by Allan Ramsay at Edinburgh in 1725, the year in which he pub-

lished the 'Gentle Shepherd.' They were not introduced to London till 1740, by Batho, a bookseller in the Strand, and in 1770, according to Timperley, there were only four circulating libraries in London and its neighbourhood. From that period the new institution must have advanced with rapidity. It is now general throughout Europe, though England and Germany are perhaps its most congenial soils. It has had the effect of fostering the production of a peculiar species of literature—the "circulating library literature"—which was once at all events, flimsy and ephemeral to a proverb.

Many of the London libraries of this kind were, even in the 18th century, of considerable dimensions; but an establishment of this class has been developed by Mr. Charles Edward Mudie, in the space from 1840 to 1860, into quite a new stage of influence and importance. Mr. Mudie, by taking hundreds and even thousands of copies of particular books, is enabled to supply at his, not their risk, the demand of country circulating libraries which are in communication with him, and it sometimes happens that two rival establishments in a country town both announce that they are connected with Mudie. Even the second largest library in London—that of the London Institution in Finsbury Circus,—takes out a subscription of 100*l.* a-year to procure from Mudie the temporary loan of such volumes as the management does not think worthy of a permanent place in the collection. His influence was even beginning to extend abroad, and his books to circulate at Paris, by means of a branch establishment there; but we believe that this has been abandoned in consequence of the difficulties occasioned by the Custom House and the prohibition of some books in his catalogue. The development of this great establishment appears to have been fatal to innumerable book-clubs, or at least to have induced them to abandon the old plan, of selecting the books for themselves and disposing of them after use among their own members, for that of procuring them from Mudie, and of course returning them to him when they are read. One effect of the system not to be admired is that it substitutes the decision of a single purchaser for that of thousands; but as that purchaser's decision is a costly one, and made at his own risk, he is not likely to favour his own taste in many cases in opposition to that of the public. The great mass of the books, as soon as they begin to fall out of circulation, are disposed of at reduced prices, and it is on the terms on which this can be managed, and the adroitness with which it is effected, that the profit and loss of this vast machinery must depend. The announcements of the augmentations of the library have gradually swelled up to "150,000 volumes a-year;" but this of course affords no measure of what is the real augmentation, probably little more than 1000 volumes being annually added to the permanent stock. The establishment is almost as unparalleled of its kind as its near neighbour—the British Museum.

Another large circulating library in London is of a different constitution and superior order—the London Library, in St. James's Square, established by a society of literary men, who by the payment of an entrance-fee and an annual subscription, or by an annual subscription alone, obtain the right of borrowing books from a library which comprises, among other volumes, the folios of the 'Acta Sanctorum.' The London Library is, in fact, a proprietary library of not an unusual type, except that the circulation of its volumes is made the prominent feature. The now extinct Surrey Institution and Aldersgate Street Institution also circulated their books, and the Russell Institution is constituted on the same plan.

When several establishments of this kind exist in a capital, there is certainly less inducement to allow the books which belong to the national library to circulate beyond its walls. Mr. Panizzi, both when Keeper of the Printed Books at the British Museum, and when Principal Librarian of that establishment, has often expressed his opinion before committees of the House of Commons and elsewhere, that it would be advisable to form supplementary institutions in different parts of the metropolis, to relieve the Museum of some of the present pressure on its resources. Should auxiliary libraries ever be formed, consisting, of course, of books of which in every case other copies might be found at the Museum, the plan might then, perhaps, be entertained with advantage of circulating the books of these libraries, as in case of loss, the loss would not be so serious. But with regard to a great national library, the preservation of books is as main an object as their collection. Such a library is not for the use of one generation only,—in fact, some of its uses are only developed by its passing into the hands of successive generations. It should be exposed to no other risks than such as are absolutely inevitable. The testimony of Molbech, the librarian of the Royal Library at Copenhagen, where lending is permitted, is to the effect, not only that the risk is greater, as must of course be the case where the books are removed from supervision and control, but that in practice great damage is found to ensue. It would, perhaps, be expedient to examine the subject more closely before a final determination was come to on either side; for while the Bodleian library is strictly non-circulating, the books are freely lent out to the members of the University from the University library of Cambridge, and yet any material difference in the condition of the two libraries, to the disadvantage of that of Cambridge, is certainly not a matter of public notoriety. Even if it should be found inadmissible to adopt the freedom of borrowing practised in foreign libraries, and the want of which in England is so loudly complained of by foreign scholars, a proposal made in 'Fraser's Magazine' for June, 1860, by

Mr. Spedding, the editor of Bacon, might be taken into consideration. Mr. Spedding proposes that if a scholar in London be desirous of consulting a manuscript or rare book in the Bodleian, not existing in the Museum collection, he shall communicate his wish to the Oxford authorities, and they, if they entertain his application, shall transmit the books required, not to his or to any private address, but to the authorities of the British Museum, who shall retain the book for a certain period in their custody and send it to the Reading Room, under the same guardianship and supervision as their own books. Of course, under similar circumstances, a book might be sent from the Museum to the Bodleian, and there might be a certain number of libraries with which the communication should be kept up. By this ingenious arrangement some of the advantages proposed by the lending system would certainly be afforded, under safeguards not now obtainable; but there would still remain the strong objection, that a reader wishing to examine a particular book known to be in a particular library, might be subjected to a disappointment which he now is in no hazard of. This objection is tersely stated in a passage from a letter by Niebuhr, which was quoted by the commissioners for examining into the University of Oxford. "It is lamentable," writes Niebuhr from the University of Bonn, "that I am here much worse off for books than I was at Rome, where I was sure to find whatever was in the library, because no books were lent out; here I find that just the book which I most want is always lent out." There are few libraries from which books are lent of which stories are not current respecting the abuse of the privilege, of volumes kept for years by persons too high or too venerable to be questioned. The rules of such institutions are often laxly observed by those from whom we should least expect such disregard. In Walter Scott's correspondence with Southey there is a passage in which he recommends him not to show publicly a book which he had sent him, because it belongs to the Advocates' library, and it is forbidden for those books to be sent out of Scotland.

Our theme has hitherto been public libraries, but the observations which have been hazarded with regard to purchasing, arrangement, and cataloguing will be applicable, with some alterations, to private libraries also. In many countries in which great private libraries have been once prevalent, and diffused a useful light, the rising of a great public library has dimmed their lustre, and even occasioned their extinction. Many a smile has been excited by the maxim of the enthusiastic engineer, that rivers were made to feed navigable canals, but it may be well maintained that the chief use of private libraries, after they have run their course for a generation, is to feed public collections. Nothing can be well more misplaced than the regret expressed by Evelyn and others at the non-continuance of libraries as heir-looms in certain families. If, indeed, a private library be generously opened as some have been to the application of every scholar, and be made subservient to general use, nothing better can be wished for while it lasts, but a library like this, though nominally private, is in reality a public one. So, many a nobleman's park in the country, which is open to his neighbours, is as conducive in its degree to the public benefit as one of the public parks of London. But the case is different when, as with Beckford at Fonthill, a proprietor surrounds his estate with a high wall, and shuts himself up in selfish magnificence, and in England the instances are few in which private libraries have been other than private. But even if liberality in this respect had been much more frequent and conspicuous than it has been, it is surely a far more healthy state of things that in future it should be looked to as a staff, and not as a crutch; that progress in literature should be released from dependence on the favours of the great. In the case of a private library which is given or bequeathed to public use, the collector is a public benefactor of a high order; in the case of one which is broken up at its collector's death, its breaking-up may possibly be just as useful as its collection; in the case of one kept in private hands for generation after generation, it is more than probable that an injury is done to the public by withdrawing from public use what is not turned to private account. Among the many memorable circumstances connected with the sale of the memorable Valdarfer Boccaccio in 1812, perhaps the most striking is, that the purchaser, who gave the highest price for it ever given for a book, had at the time, unknown to himself, another copy in his own library, which had descended to him by inheritance. The only instance in which it would seem desirable that a great private library should remain in a family is in the case of a great author. It seems an appropriate tribute to his memory that Sir Walter Scott's collection should be kept entire at Abbotsford, but to keep the library of an ordinary collector together in respect to his memory, is not at all justified by the case of Scott. The monument which is erected to him in the centre of Edinburgh might as well be quoted as a justification for the ostentatious columns in honour of aristocratic landlords, which it is now the practice to raise from the so-called voluntary subscriptions of their tenants. To be incorporated in a public library, or rather to be distributed in several, is the proper "euthanasia" of a private collection.

Having thus examined the composition of a library of the very first order, and the rules that have been proposed for collecting and managing such a library, with a view of making it of the utmost possible public benefit, it remains to take a general survey of libraries, not in the abstract, but the concrete,—of the history and statistics of such collections as have from time to time been formed.

The most ancient library of which we have any authentic account is that of Osymandias, king of Egypt, supposed by modern Egyptian scholars to have reigned about fourteen centuries before Christ. Diodorus Siculus, who gives a minute description of the monument of this king, mentions that there was in it a room containing a "sacred library," and bearing an inscription translated into Greek by $\Psi\upsilon\chi\eta\varsigma$ 'Iarpeion, which has been playfully rendered "the Apothecaries' Hall of the Soul." Champollion believed that he had discovered this hall in the palace near Thebes, from which the "Memnon's Head" now in the British Museum was taken. It has been supposed that all the libraries of ancient Egypt were merely collections of sacred books; but a contrary inference may be drawn from the circumstance mentioned by Eustathius, the commentator on Homer, that Homer was absurdly accused by some ancient calumniator of having stolen his 'Iliad' and 'Odyssey' from a library in Egypt. It is singular that it was on the soil of Egypt that the most famous library of all antiquity afterwards arose. The first public library in Greece was formed at Athens by the enlightened tyrant Pisistratus, the supposed collector of the scattered poems of Homer; but according to the not very probable statement of Aulus Gellius, it was taken away to Persia by Xerxes, and only subsequently restored to Athens by Seleucus Nicanor, one of the successors to the Asiatic kingdoms of Alexander the Great. Another of Alexander's successors—Ptolemy, king of Egypt—established in Alexandria a great library, which continued under all vicissitudes the most famous library in the world for about 900 years. The most extraordinary statements are made by the writers of antiquity respecting the number of volumes it contained. Josephus relates that, on the question being put by Ptolemy, the founder, to Demetrius Phalereus, the famous Athenian exile, who had the superintendence of the library, what was the number of volumes, Demetrius replied that there were at that time 200,000, but that he hoped there would soon be 500,000. Aulus Gellius speaks of the number of volumes at a subsequent period as 700,000. There can be no doubt that, in this instance of counting, the "books" in a poem are taken as "volumes," and that the 'Iliad' would therefore be reckoned as 24, in which case it might be near the mark to assume that 700,000 volumes of the ancient library would contain about as much reading as 60,000 of a modern one. Even then the number is remarkably high for the early period of the history of literature at which the collection was made; and to account for it with any degree of probability, it is necessary to suppose that many copies of the same work were admitted, as was subsequently stated to be the case in the Mohammedan libraries of Egypt, and as was probably the case in all ancient libraries. This supposition is strongly supported by the subsequent labours of Aristarchus and the Alexandrian school of critics, who would naturally ground their improved readings on the collection of many copies of the same work. Allowance must also be made for that besetting sin in the enumeration of libraries, exaggeration; still the existence of exaggeration shows that there was something not too obviously scanty and limited to expend it upon. In the libraries of the middle ages we never hear of tens of thousands. Sixteen hundred years after the library of the kings of Egypt had been spoken of as possibly of half a million volumes, the library of a king of France was stated to contain 910. At the time that Josephus wrote, the library formed by Demetrius Phalereus and his successors no longer existed. In the wars of Julius Cæsar in Egypt, in some desperate struggles with the mercenary soldiers, the building in which it was kept accidentally caught fire, and the whole collection was consumed. The calamity was probably deeply felt by the most literary of conquerors, and in his 'Commentaries,' and those of his freedman Hirtius, there is no allusion whatever to the fact, which is however sufficiently established by the testimony of Seneca, Plutarch, Dion Cassius, Aulus Gellius, and Ammianus Marcellinus. Seneca, who refers to one of the lost books of Livy, speaks of 400,000 volumes as having perished. It seems, however, from various indications, that the library had increased so enormously previous to this conflagration, that the later part of it was kept in a separate building, in another part of the city, and thus escaped. Mark Antony, in his subsequent passion for Cleopatra, endeavoured to repair the loss of the early library of the Ptolemies by presenting to her the library of Pergamus, the collection next in celebrity to theirs. The kings of Pergamus had entered into a rivalry with the kings of Egypt in the collection of books, and the contest had been carried on so warmly that, according to tradition, the Egyptians forbade the exportation of papyrus, to which the Pergamenians responded by the invention of parchment, called from them Pergamena—the name from which the English one is derived. When Mark Antony presented the library to Cleopatra it amounted, according to Plutarch, to 200,000 volumes, and, being added to the preserved collection, formed thenceforth the new library of Alexandria, which continued the first in the world. The Romans, though Egypt was their province, respected its integrity; and when a conflagration destroyed the public libraries at Rome, the emperor Domitian contented himself with sending copyists to Alexandria to repair the loss. Its subsequent history is involved in much obscurity, and indeed many of the circumstances which have already been narrated are not established upon the most solid basis. There seems to be reason to believe that a great destruction of the library took place in the assault of the Christians on the temple of Serapis, on the triumph of Christianity over heathenism, A.D. 389; and

the collection is asserted to have finally perished in A.D. 638, when the Mohammedans, under Amru, conquered Egypt.

The story told by Abulpharagius and doubted by Gibbon is well known: that Amru applied to his master, the caliph Omar, for a decision as to what was to be done with the library, and received the reply, that if the writings of the Greeks agreed with the Koran they were useless, and need not be preserved; if they disagreed they were pernicious, and ought to be destroyed; and that in consequence the books were devoted to the heating of the public baths. This massacre of intellect, if it really took place, was afterwards paralleled, if Arabic historians tell truth, by similar massacres of Mohammedan literature on the part of the Christians. At the capture of Tripoli, in Syria, by the Crusaders under the Count de St. Gilles, in the 12th century, a priest who entered the great library took down one of the books and found it was a Koran, a second and found it was a Koran, a third and fourth with still the same result, on which he exclaimed that the place was full of nothing but Korans, and fire was set to the whole collection, of which but a few volumes escaped. He had, in fact, says the Arabic historian, entered the room of the Korans, of which there were 50,000 copies in the library. Without of course accepting the statement of the number of Korans, it may be supposed that there was a large collection of them at Tripoli, and that the library was burned by the Franks on that account. Similar deeds are recorded of the Christian conquerors of Granada, and of Cardinal Ximenes, the patron of the Polyglott Bible.

The history of the libraries of ancient Greece is singularly obscure, and they seem never to have had any distinguished prominence,—a fact which is not in favour of the theory, that the civilisation of a people may be estimated from its public libraries. The library of Pisistratus has already been mentioned, its abstraction and its restoration by Seleucus. Its subsequent stay at Athens must have been short, for Sylla is recorded, on his conquest of Athens, to have carried off all the libraries to Italy, where, however, he does not appear to have given them to the Roman public, but to have left them to his son, who kept them in his villa at Puteoli. A story which is told by Plutarch in his Life of Alcibiades, affords a strong indirect testimony to the general existence of collections of books in connection with the schools at Athens. Alcibiades, it is said, was upon one occasion desirous of referring, when in a school, to a passage in Homer, and was told by the schoolmaster that he had no copy of the poet, on which, for his sole rejoinder, he gave him a box on the ear.

The honour of founding the first public library at Rome was reserved for Asinius Pollio, in the reign of Augustus, though Julius Cæsar is said to have entertained the design, perhaps as a compensation to learning for his involuntary destruction of the Alexandrian, and to have intended to nominate Varro as the librarian. Previously to Pollio, Lucullus is recorded to have been singularly liberal in opening his library to the use of the learned; and after him Augustus added two public libraries to the ornaments of the capital, the Octavian and the Palatine. Many others were added by subsequent emperors, who seem to have had a pleasure in attaching their names to new foundations, the most conspicuous and celebrated of which was the Ulpian, so called from one of the names of Trajan. These libraries appear to have had a great effect in diffusing over Roman society that literary air which is so remarkable a feature in the letters of Pliny, and which occasionally reminds the reader so strongly of the Paris of the 18th century. By some allusions in Ovid's 'Elegies,' written after his banishment, in which he questions if his new productions will be allowed to take their place beside the old in the public libraries, it appears that the new works of living authors found a place there, and this was probably the most effectual mode of publication. A few copies in the public libraries would probably—like a few copies in the circulating libraries of our own time—diffuse the knowledge of a new book more effectually than hundreds in private hands. At the same time, the frequent censures of Seneca and others of the "bibliomania" prevalent in his time, show that magnificent private libraries were then, as they have again begun to be in the last four centuries, a favourite means of expending and displaying wealth.

It is singular that of the great Roman libraries it is seldom mentioned of how many volumes they consisted or were supposed to consist. Julius Capitolinus, in his 'Lives of the Gordians,' mentions of the emperor Gordian the Younger, that he inherited the library of Serenus Sammonicus, his preceptor, and that that library amounted to 62,000 volumes, which is spoken of, as it well may be, as an enormous number. Another glimpse into the libraries of the period is given by the circumstance mentioned of the emperor Tacitus, that he commanded by a particular edict that the works of his ancestor, Tacitus the historian, and those of various other historical writers, should be transcribed in ten copies every year, and the copies distributed among the public libraries. In the time of Constantine the Great, the number of these establishments at Rome is stated to have been nine-and-twenty.

The tradition of the ancient libraries was continued by the Byzantine emperors through the long and dreary eleven hundred years which elapsed between the transference of the empire to that city, and its capture by the Turks. Constantine the Great founded a library at Constantinople, for the formation of which it is supposed that contributions were levied on the nine-and-twenty in the heathen temples at Rome. The passage is well known in the writings of Julian the Apostate: "Some are fond of horses, some of birds, and others of

wild animals; but from an infant my mind has been possessed with a vehement fancy for acquiring and possessing books." Julian is recorded to have founded a public library in the grove of Daphne, which was the park of Antioch. Zonaras and Constantine Manasses relate a story of a library founded by the emperor Zeno, to which were attached a principal librarian, bearing the title of the "Œcumenical Doctor," and a body of twelve assistant-librarians, who were consulted as oracles in affairs of state; and they narrate that when the emperor Leo the Isaurian, the great iconoclast, found it impracticable to convert them to his opinions in favour of the destruction of images, he caused combustibles to be secretly laid round the building at night, and, setting fire to the pile, destroyed in one conflagration the library and the librarians. The truth of the narrative is supported by Baronius and some other Catholic writers, but it is now generally considered more than questionable. Photius, the patriarch, the contemporary of King Alfred, who in his 'Bibliotheca' of the date of a thousand years ago, so curiously anticipated the plan and utility of a modern Review, must at least have had access to the two hundred and eighty authors whom he analyses.

The Mohammedan antagonists of the declining Byzantine empire were according to their own accounts, on more than an equal footing with them in regard to libraries. The statements of Arabic historians on this subject seem in fact to belong to the 'Arabian Nights.' Quatremère, in his 'Récherches sur l'Égypte,' quotes several narratives which are altogether incredible as they stand, but which may be taken as grounds for believing the existence of libraries of a size and extent quite different from the contemporary collections of Christendom. Ibn Aby Tay, according to M. Quatremère, affirms that the library of Cairo contained 1,600,000 volumes, and was the largest in all the Mohammedan empire. M. Quatremère also tells us, on the second-hand authority of Ibn Ferat, that Tahia Ben-Aby-Tay, which seems to be only another form of the name of the same pseudo-historian, asserted that the library of Tripoli, in Syria, contained 3,000,000 volumes on theology only. The statements, to say nothing of their intrinsic incredibility, contradict each other. Makrizi, a better authority, speaking of the library of the Caliphs, describes it as filling forty chambers, and as containing 18,000 volumes on the sciences, and 2400 copies of the Koran.

The Arabs in Spain were the most literary of all the Arabs, and in their history we find mention of immense libraries, and also of bibliomania, a disorder of literature which indicates a general flourishing condition of the patient. According to Al-Makkari's 'History of the Mohammedan Dynasties in Spain,' translated by Gayangos, the inhabitants of Cordova were renowned, in the 10th century, for their passion for forming libraries. "To such an extent did this rage for collection increase," says Ibnu-Said, an Arabian author, "that any man in power, or holding a place under government, considered himself obliged to have a library of his own, and would spare no trouble or expense in collecting books, merely in order that people might say—'Such a one has a very fine library, or he possesses a unique copy of such a book, or has a copy of such a work in the handwriting of such a one.'" A great library was formed at Cordova by the caliph Al-hakem, who caused all sorts of rare and curious books to be bought by his agents in Cairo, Bagdad, Damascus, Alexandria, and other great cities of the East, and who was currently reported to have amassed a collection of not less than 400,000 volumes. The historian Ibnu-l-abbar, to increase the marvel, states that, "to [give an idea of Al-hakem's immense erudition, it will only be necessary to record a well-ascertained fact—though strange to say neither Ibnu-l-faradhi, nor Ibn-Bashkuwal have mentioned it in their works—namely, that not one book was to be found in Al-hakem's library, whatever might be its contents, which the caliph had not perused, writing in the fly-leaf the name, surname, and patronymic of the author, that of the tribe or family to which he belonged, the year of his birth and death; after which followed such interesting anecdotes about the author or his work, as through his immense reading he had derived from other writers." Even those who have had no experience in cataloguing will agree that to do this for a collection of 40,000 volumes, not to say 400,000, would require no common share of industry. On the death of the caliph, in A.D. 796, the throne of Cordova was usurped by Al-mansur, who in order to conciliate the favour of the Mohammedan theologians, ordered all the books on philosophy and similar subjects to be destroyed, and they were accordingly either burned in the public squares or thrown into the wells and cisterns of the palace. Finally, on the overthrow of the dynasty of the Omniades by rebel princes, Cordova was invaded and sacked, the palace of the caliphs was levelled with the ground, and the books of the splendid collection of Al-hakem taken as plunder, and sold in distant countries at the lowest prices.

While the number of books among the Arabs was so incredibly large, among the Christian nations the number was inconceivably small. The instinct of collecting and that of preserving libraries seem in some cases to have been equally deficient. Charlemagne was persuaded by his English librarian, Alcuin of York, to collect a library equal to that which Alcuin had seen in England; but in his will, the monarch expressly directed that it should be sold, and the proceeds given to the poor. The monastic libraries are usually spoken of as the great literary establishments of the middle ages, but the collections of monks and magnates are on the same scale of distressing poverty. The

monastic library of Fulda, which Charlemagne had increased, if not founded, in A.D. 744, was celebrated during the whole middle ages, and in the year 1561 was found to contain 794 manuscripts. In the 12th century, the monastery of Monte Casino contained 90 volumes. The church of Ratisbon possessed in 1251, a library of 500 volumes; the library of the Sorbonne, in Paris, amounted in 1292 to 1000. The chronicler Geoffrey of Beaulieu relates that St. Louis, when on the Crusades, heard of a great sultan of the Saracens who made careful search for books of all kinds, and who had them transcribed at his own expense, and placed them in libraries for the use of the learned. St. Louis resolved, therefore, on his return to his own kingdom, to have copies made of all the books of the Holy Scriptures and general edification that he could find in the different abbeys, and he collected at the Holy Chapel, still existing at Paris, numerous works of St. Augustine, St. Ambrose, St. Jerome, and other authors. This library, like that of Charlemagne, was again dispersed at the king's death, and distributed among three religious orders. In 1373, as has already been mentioned, the library of the king of France consisted of only 910 volumes.

The revival of learning which preceded the invention of printing, had already begun to produce an alteration in this state of things, when that invention came to quicken and confirm it. The middle ages may be said to terminate with this discovery, in the middle of the 15th century.

So much has already been incidentally said of the continental libraries of modern times, that to enter on the subject in full would be to go over ground that has been already trodden. It will therefore be sufficient to treat of it here with comparative brevity. Italy was the first country to be conspicuous in this point of view. Italy is still rich in libraries of the second and third magnitude, but can boast of none that belongs to the first. It has been already mentioned that the Vatican, though rich in manuscripts, is now shown to contain not more than 100,000 printed books. There is a larger library in Rome itself, the Casanata, known by its admirable catalogue, made by the astronomer and bibliographer, Audiffredi, and said to contain 120,000 volumes of printed books and manuscripts. The collection, located at Naples since 1804, called the Biblioteca Borbonica or Bourbon library, and reputed to contain 200,000 printed volumes, is probably the largest library in Italy. The reputation of being one of the best belongs to the Brera library at Milan; a collection which, formed from the library of the suppressed order of Jesuits in 1772, was augmented by that of Count Firmian, the Austrian governor of Lombardy, a famous collection, in the published catalogue of which one volume is occupied with the English books. The numbers of the Brera were at one time greatly overstated; they have, upon counting, been reduced to about 100,000. The other great library of Milan, the Ambrosian, consisting of more than 100,000 printed books and 15,000 manuscripts, is that which attracted the attention of Europe in the early part of the 19th century, by the discoveries made in it by Angelo Mai, the librarian, of ancient palimpsests. The library was founded in the 17th century by the almost canonised Frederic Borromeo, the cousin of St. Charles of the same family, who left the singular injunction, that the manuscripts should not be published. At Bologna, the institution founded by Count Marsigli, the martial companion of Prince Eugene, counts among its 150,000 volumes a collection of Oriental manuscripts, brought by the count from the wars; and among its printed books a collection, scarcely less rare in Italy, of German poetry and literature, introduced by its librarian the great linguist Mezzofanti. Venice boasts in the library of St. Mark, a collection which was founded by Cardinal Bessarion, but of which Roncelli can only state by conjecture that it contains 100,000 volumes. It is subject to less doubt that it is one of the most magnificently lodged libraries in Europe, having been removed from the library buildings in the place of St. Mark, to the great hall in the Doge's palace. Florence is remarkable also for the magnificent building designed by Michael Angelo, in which is enshrined the Laurentian library, a collection of manuscripts so named from one of its founders, Lorenzo de' Medici. The great collection of printed books at Florence is called the Magliabecchian, from its founder, Magliabecchi, the celebrated "book-glutton," who was librarian to the Grand Duke, and who at his death in 1714, left his library to the public, and all his property for the purpose of enlarging and preserving it. His friend Manni, in 1731, added his own collection from respect for the memory of Magliabecchi; and in 1771, when the Grand Duke Leopold munificently gave up his own library for the public benefit, the printed books were sent to the Magliabecchian, and the manuscripts to the Laurentian. A few years ago Molini, the librarian, prepared to carry out in full the idea of bringing together in one collection all the printed books in Florence belonging to the public, and in another all the manuscripts; but the project, though commenced, seems to have stopped half way. One of the most interesting libraries in Italy is that of Ferrara, which though not of earlier date than 1747, contains 90,000 volumes, and among them the autographs of part of the 'Orlando Furioso,' of part of the 'Jerusalem Delivered,' and of Guarini's 'Pastor Fido.' Of the remaining libraries of Italy, that of Parma, remarkable for containing the Hebrew collection of De Rossi, was said by Roncelli, in 1846, to amount to 90,000 volumes; that of Piacenza, to more than 40,000; that of Lucca, to more than 50,000; that of Turin, to 120,000. Generally speaking the

libraries of Italy appear to have been collected as much for display as use. They are usually confined to classical and modern Latin literature, and to that of Italy and France; and even within those limits to certain classes,—to books which have been always considered library books. To this of course there are exceptions; we have heard of an Icelandic library at Palermo; but they are rare. In his excellent history of Italian literature, Tiraboschi, himself the librarian of Modena, takes particular notice of the progress of libraries, century by century. An animated description of the Italian libraries is the principal feature in Valery's 'Voyage en Italie.' The rules of admission to these libraries are less liberal than those which prevail in France and Germany, and the number of days of closing is unusually large. There were in 1851, according to Mellado's Spanish Encyclopædia, published in that year, 29 public libraries in Spain, containing altogether about 627,200 volumes—a number for the whole country less than is accumulated in some single collections out of Spain. The three most interesting were, the national library at Madrid, containing, since it had received the contributions of the conventual libraries, about 200,000 volumes; the library of the Escorial, containing 24,000 volumes only of printed books and 4000 of manuscripts, chiefly Arabic; and the "Columbian" or cathedral library of Seville, remarkable for possessing some works which once belonged to Columbus. The libraries of Portugal have had no "golden age." In the report on the national library published in 1844, a list which is given of the foreign purchases of seven years occupies little more than four pages. The fate of one library in Portugal has been unique. In 1807, when the royal family emigrated to Brazil from the invasion of the French, the royal library sailed in the same fleet, and now forms the imperial library at Rio Janeiro. It was probably at the time of its arrival in Brazil the largest library in America.

France is in many respects a model to the rest of Europe with regard to libraries. It contains a collection of the first magnitude in the capital; it has several others of only less importance both in the capital and the provinces, and scattered over its surface it has many collections of different degrees of interest freely accessible. This description, which implies high praise, is not applicable in all its parts to any other country. The Royal Library of France dates its origin back to the 15th century, before the invention of printing, but it did not begin to be of real importance till the reign of Louis XIV. He is said to have found about 5000 volumes in it at the commencement of his long reign, and to have left 70,000. Under Louis XIV. the collection was not freely open to the public: the Italian minister of his minority, Cardinal Mazarin, was far more advanced than his French master in this respect. The first library of 40,000 volumes, which Mazarin collected with the assistance and advice of his librarian, Naudé, was treated, not as a private, but a public library. "From its door," says Naudé, in a dialogue he published, "shall resound that cry never yet heard in the republic of letters—'Come, all ye who desire to read, and freely enter in.'" It was this library which was sold by auction, in the course of the insurrection against Mazarin, by order of the Parliament of Paris, who directed that part of the proceeds should be offered as a reward to whoever should capture the Cardinal dead or alive. The minister, after his triumph and return to undisputed power, collected a second library, which he left to the public at his death, and which is now kept in the same building with the library of the Institute at Paris. It was probably the existence of this public collection which led to the opening of the royal one, which took place in 1737, some years after the grandson of Louis, seated on the throne of Spain, had already opened a public library at Madrid. It is difficult to trace with clearness the phases of publicity of the royal library which has often apparently been less public than its regulations would imply. The judicious liberality of the minister Colbert, the favour with which accessions to the library from the exertions of French ambassadors in foreign countries were looked upon, and a number of favourable circumstances, had gradually led, at the period of the Revolution, to the accumulation of a collection of books which, though it appears it was surpassed in mere numbers by that of Zaluski, was then the most valuable in Europe, and could only be rivalled in that respect by the imperial collection at Vienna. In foreign literature, however, its deficiencies were in many respects remarkable—in German and English especially. Great care had been bestowed, and justly, in amassing curious manuscripts from the furthest parts of Asia, and Fourmont boasted that, "for the literature of China, of Tartary, and of India, the king's library was then the richest library in Europe;" but it had no set—and it is doubtful if it has now—of the 'Gentleman's Magazine.' The history of the library during the Revolution is painfully interesting. Many of the librarians were involved in the calamities of that dreadful period. Barthelemy, the author of 'Anacharsis,' was sent to prison; three others, Carra, Girey-Dupré, and d'Ormesson, suffered by the guillotine; Champfort, the colleague of Carra, on being arrested in the library, endeavoured to commit suicide, and though not killed on the spot, died finally of the wounds inflicted. In the height of all this, the institution flourished, and the numerous acquisitions it made from the suppressed convents, raised it to the position it still occupies, of the first library in Europe. Amid the storm that raged around, one political fanatic, Henriot, proposed to burn the whole collection, and some courage and conduct were requisite to oppose and avert the execution of this and similar measures on a

smaller scale, which were proposed as a tribute to the popular aversion to priestcraft and monarchy. At the same time proposals were occasionally brought forward which were singularly judicious. In 1795, Villar, deputy of La Mayenne, presented to the Convention a report, in which he pointed out, among other things, as indispensably necessary, the purchase of the books printed from year to year in France, and of those printed from year to year abroad, and laid great stress on the importance of seizing opportunities as they occurred, and of disregarding the suggestions of a false economy, which, he said, in such cases does but multiply difficulties and lead to vain regrets. The Napoleonic period was chiefly distinguished, in regard to the library, by its passion for enriching it by foreign conquest. These trophies had more or less completely to be restored when foreign conquerors were in their turn twice masters of Paris. After the Restoration the library quietly preserved its place at the head of European establishments, without much need to guard against rivalry, and the subject of little commentary but praise. During this time it was customary to speak of Van Praet, the librarian, as "the living catalogue," and it appeared to be quite unsuspected that there was need of any other. After 1830, complaints began to arise that so little had been done to reduce to order the chaotic mass that had been thrown into the library in the revolutionary times, and the more orderly accumulation since, that it was impossible to know what books were present in the library and what deficient, and an agitation gradually arose for a new and complete catalogue. Dr. Martin Lister, in the account of his journey to Paris, in 1698, published in 1699, said, with much simplicity, "They work daily and hard at the catalogue, which they intend to print. . . . They purpose to put it into the press this year, and to finish it within a twelvemonth." They began to print in 1735, and have not finished in the 162 years that have elapsed since the visit of Dr. Lister. Ten folio volumes of the work, perhaps the handsomest volumes of a catalogue that have ever been printed, did but commence the labour, and all intention of completing that edition of the catalogue has now been abandoned for about a century. In 1855 came out the first volume of a new catalogue, commencing the division 'History of France,' and six volumes of that division have now appeared, and one volume of 'Medicine.' In regard to foreign languages, the errors in these volumes are far from unfrequent, and oversights of various descriptions may be pointed out. Still the existence of a printed catalogue of such extent on so interesting a subject is a boon, and if it proceeds as it has begun, all Europe will hail its success. In 1858 a commission, which was appointed by the French government to inquire into the affairs of the library, sent a commissioner to England in the person of M. Prosper Mérimée, the celebrated novelist and archæologist, who in a report made on his return, eulogised highly various of the arrangements introduced at the British Museum during Mr. Panizzi's administration, which he recommended for adoption in France. In the report of M. Rouland, the Minister of Public Instruction, to the Emperor of the French in 1860, the report of the commissioners is referred to as the recognised basis of the future administration of the library, and at the same time the Emperor's attention is called to the necessity of increased exertion to save the great establishment of France from the danger of being surpassed by its foreign rivals. The library may now be estimated to comprise about 880,000 volumes—the number given in a former part of this article (col. 206) being based on an erroneous assumption of the number of pamphlets, &c., as 735,000 instead of 750,000. M. Rouland proposes the measure of incorporating, in the vast collection of Paris, all the books that it does not already possess which are to be found in the other public libraries of the capital—a measure which he supports by the authority of the first Napoleon. That he confines this proposal to the libraries of Paris only, and excepts the departments, shows, however, that the minister anticipates opposition. No objection of any plausibility could be opposed to the plan of including such books in the catalogue—a plan which has already been carried into effect in Bajot's catalogue of the four libraries of the French marine, in which the books in all the four are given indiscriminately in one order of arrangement, with an indication of the collections in which they exist, sometimes in one only and sometimes in all the four.

In addition to its great collection, Paris boasts of several other libraries of large extent. The Mazarine library has 132,000 volumes, that of St. Geneviève was officially returned in 1849 as of 180,000 printed volumes and 3500 manuscripts; that of the Arsenal is said to contain more than 202,000 printed volumes, and 6000 manuscripts. The library of the Arsenal is a special one, and said to be the richest in Europe in works of fiction and amusement. There are also a City library and some minor collections.

The provincial libraries of France are scattered thickly over the country, and many of them are on a level in point of numbers and value with the secondary libraries of Paris. That of Lyons is said to contain about 120,000 volumes of printed books; that of Rouen in 1855, was of 110,000; that of Bordeaux in the same year, 123,000; of Besançon 80,000; of Strasburg 180,000. Many of these institutions have been largely augmented of late years, and they vary in composition and character. The strength of the library of Rouen consists in modern literature, and of the arts and sciences; that of Strasburg is remarkable for its abundance of periodical publications. Many of the smaller libraries are interesting from their history and historical

associations; and they often show signs of diligence and sagacity in the choice, arrangement, and management of the collections. One of the points of contrast which produces the most forcible impression on an English visitor of Boulogne from Dover or Folkestone, is the striking superiority in regard to opportunities for self-cultivation and improvement enjoyed by the residents in French provincial towns.

In Germany, the land of universities, the number of eminent libraries is, as might be expected, large. Five great collections of special interest are at present in existence there—the Imperial Library at Vienna, the Royal Libraries at Munich, Dresden, and Berlin, and the University Library at Göttingen. The library of Vienna, founded, it is said about 1440, consisted in 1660, when Lambecius was appointed librarian, of about 80,000 volumes, and a Latin inscription to that effect was placed over the door, with a declaration, that the collection yielded to no library on earth in the number and value of its books and in the variety of languages it contained. Augmented by the addition of the collections of several of its librarians—Blotz, Tengnagel, Lambecius—as they successively deceased, it also acquired at his death the 15,000 volumes of Prince Eugene. The magnificent building which was afterwards erected for it by the architect Fischer of Erlach, continued for many years the finest library-room in Europe. Denis, who published in 1775 his excellent 'Introduction to Bibliography,' was unhappily tempted, in a moment of weakness, to assert that the library then contained about 300,000 volumes; and, when in 1796 he had himself become chief librarian, he repeated the assertion with the authority which his position gave him. Balbi, in his 'Essay on the Library of Vienna,' published sixty years afterwards, demonstrated with sufficient certainty, that even in 1789 the number could not have been more than 196,000, but he maintained that the statement of 300,000 which was formerly erroneous had now in the lapse of years become correct, while the analysis of his own statement showed, on the contrary, that the proper cypher was far below it. There can be little doubt that now, in 1860, that number has at length been really attained and passed, but the exact amount of what the library contains is still uncertain. Petzholdt, in 1853, stated it at 385,000. The liberality of the imperial court has not been extended largely in the establishment. When Mosel published his history of the library in 1835, he stated that the number of visitors to the reading-room having increased beyond what the room would conveniently hold, the remedy had been resorted to of not allowing more than a certain number to enter, and no new reading-room appears to have been erected since. The space for the placing of books is so limited, that in the magnificent architectural saloon, rows of volumes are said in some cases to stand four deep. The library of Vienna is, in its composition, a fine specimen of a great palatial library, mainly formed by the gradual accumulation of centuries.

The library of Munich, originally founded in the period between 1550 and 1579, was for more than two hundred years a collection of no note: the number of volumes in 1795 being known to be not more than 11,000. In 1803 a totally new era for the library began, by the dissolution of many of the great monasteries of Bavaria, the libraries of which were transferred to the royal collection. These libraries, being situated for the most part in or near the country where the earliest productions of printing were issued, and having been in a flourishing state at the period, were remarkably rich in early specimens of the art; and the consequence of bringing them together was the formation of an unequalled collection of these "cradle-books," or "incunabula," and also of a great assemblage of duplicates. The kings of Bavaria, taking a pride in the immense stores of learning of which they had become masters, added liberally by purchase to the collection, which would otherwise have been singularly one-sided, and in 1843 a new building was added to the other remarkable edifices of Munich, in which the ground-floor was occupied by the archives of the kingdom, and the first-floor by the great library. One feature of the construction does much credit to the architect, Gaertner, and demands especial notice. There is no book throughout the building which cannot be readily reached by the hand, without the necessity of using steps or ladders, a necessity fraught with accident, which, as imposed in many libraries, has caused the death of several librarians, and is likely to cause the death of more. The numbers of the library of Munich have been a question for years—the reasons have been already given for which 440,000 volumes may be assumed as the nearest approximation. The library at Dresden, begun in 1556 by the then elector of Saxony, first rose into importance after the year 1760. The Counts Bünaü and Brühl, of Dresden, were long rival book-collectors—Bünaü forming an excellent collection on the German plan, studiously and economically assembling from all quarters the books that threw most light on literature, history, and science; his rival, Count Brühl, the frivolous favourite of Augustus III., elector of Saxony and king of Poland, giving a high price for choice copies and rare editions, such as are more prized in general in the libraries of Italy than of Germany. Within four years the death of these magnates placed both their libraries on sale, and both were bought by the king, who thus formed a library at once of intrinsic and bibliographical value. The Bünaü collection was of more than 42,000 volumes, and the Brühl of 62,000; and the former is still well-known to scholars by its excellent though unfinished classified printed catalogue, made by the librarian, Francke. The library at Dresden, which is located in the magnificent Japanese palace, continued

for some time to receive liberal augmentations, but has been of late years insufficiently supplied with funds. A volume upon it was published by the late librarian, Falkenstein, of a kind such as it would be desirable to have for every library,—a description of a walk through the rooms, with a brief but lucid statement of what are the treasures in every department. The number of volumes is now stated at over 300,000.

The royal library of Berlin is the modern representative of the electoral library, founded in 1650. It has had the honour of receiving the attention of Frederick the Great, the account of whose proceedings with it is a record of weak caprice which may tax even the admiration of Mr. Carlyle. Its augmentations have been more gradual than those of Munich and Dresden, and its progress has been accelerated instead of diminished during late years, under the administration of Dr. Pertz. A collection of Sanscrit manuscripts, a collection of Aldines, and above all a collection of German literature—the Meusebach library of 36,000 volumes, have much increased its value. The number of volumes is now stated at over 500,000.

The university library at Göttingen is remarkable for the novelty of the grounds upon which it attained its celebrity. Founded with the university itself, in 1734, it already contained from 50,000 to 60,000 volumes, when Heyne went to Göttingen, in 1763, and from that period it began to manifest the effects of the industry and learning which as its librarian he began to devote to it. With a liberal but not profuse expenditure, judiciously directed, he produced, in the course of a few years, a library in which every kind of research, literary or scientific, might be pursued with a success beyond that attainable in other libraries, because this collection had been brought together by system and most other collections by chance. Whenever the university of Göttingen was mentioned, the library was sure to be mentioned with it. It was the silent and permanent Professor which drew the most students to Göttingen. Its arrangements with regard to cataloguing and otherwise were cited as all but perfect, and a diligence was expended upon them which certainly claimed admiration, even if in some cases carried to excess. Of late years its fame is not quite so bright as formerly. Statements have varied as to its numbers: an official return made to the English Foreign Office in 1850 gives the number of volumes as about 350,000, counting as a volume whatever comes as such from the hands of the binder, whether containing a pamphlet of a few pages or fifty such pamphlets.

There is also an important library at Stuttgart, belonging to the King of Wirtemberg, and stated to contain in 1860 upwards of 200,000 volumes, including the largest collection of Bibles in the world: and an interesting library at Wolfenbüttel, formed by the Dukes of Brunswick, one of whom, in the latter part of the 17th century, found his chief pleasure in writing the catalogue. Every part of Germany abounds with libraries, of interest from their antiquity or their curiosity, of all of which some mention will be found in Dr. Julius Petzholdt's often reprinted 'Handbuch der Deutschen Bibliotheken,' in which he also gives lists of the books written respecting them, their catalogues, &c. The libraries of Germany, compared with others in the principal countries of Europe, have been remarkable for their comprehensive character. When the Italian libraries chiefly consisted of Italian books, the Spanish libraries of Italian and Spanish, the French of Italian, Spanish, and French, the English of Italian, Spanish, French, and English, all with the addition of the classics,—the German consisted of all these languages, with the addition of German. It is in German libraries also that are most frequently to be found the leading volumes of the secondary languages of Europe, but they are not remarkably rich in this point of view. There is no large collection of Russian, apparently, in any German library, with the exception of that of Göttingen, in which one was commenced but not adequately continued.

The other countries of continental Europe must be passed over on the present occasion with very brief notice. The libraries of Belgium are mostly of recent formation, a great destruction among the old collections having taken place at the time of the French Revolution. Voisin, the historian of the Belgian libraries, states that the Jesuit libraries alone numbered more than 800,000 volumes in Belgium at the time of the dissolution of the order, and that in 1840 the whole number of books in the public libraries was less, amounting altogether to little more than 700,000. A royal library was first founded at Brussels in 1836, by the purchase of the collection of 60,000 volumes belonging to Van Hulthem of Ghent, an amateur who had formed an unequalled collection of books on Belgium, and the sale of whose library presented an opportunity which the government wisely determined not to let escape.

In Holland, the library at the Hague is larger than that of Amsterdam; but the Dutch collections in general are of less extent and importance than might have been expected. Denmark is remarkable among the smaller countries of Europe for the spirit and sagacity which it has displayed on the subject of libraries. The royal library of Copenhagen far surpasses every other collection in Scandinavia in numbers and interest. It is chiefly formed, like the Dresden collection, of the amalgamation of two private libraries—those of Count Thott, an eminent collector, and of Suhm, the most popular historian of Denmark. The collection of Thott was not acquired entire, but at the sale of his library of 120,000 volumes, the largest private collection ever formed in Denmark, the

royal library, to which some of his choicest works had been previously bequeathed, bought to the extent of 61,547 volumes, at an amazingly low price. This was about 1792; and nearly at the same time an agreement was formed with Suhm, who was old and childless, that after his death his collection should be added to the royal collection, in consideration of a moderate annuity, which by his death fell in in two years. This added another 100,000 volumes to the library, and placed it in that high position which it has since maintained. According to the 'Nordisk Conversations-Lexikon,' published at Copenhagen in 1858, it then contained about 450,000 volumes of printed books and 20,000 of manuscripts. The university library in Copenhagen contained at the same time about 200,000 volumes; and there was a third library in the same city, founded by the will of General Classen in 1796, and much used, since the measure had been adopted of confining it to one subject only, that of natural history. Sweden is very inferior in the matter of libraries to Denmark: the principal library is that of the university of Upsal, which is said in the 'Stockholm Conversations-Lexikon' for 1857 to contain 130,000 volumes of printed books and about 7000 manuscripts. The royal library of Stockholm only dates back to the time of Charles X. of Sweden, as his predecessor, Queen Christina, when she left the country on her abdication, took the then royal library with her, and it is now in the Vatican at Rome. The Stockholm library amounted in 1857 to 100,000 volumes of printed books and between 4000 and 5000 manuscripts, and is now (1860) about to be removed from the royal palace, where it has outgrown its apartments, to a new building which has been erected for it from the designs of a German architect.

The great Polish library of Zaluski has been already spoken of on more than one occasion. Its collector is one of the most remarkable men in the annals of libraries. His incessant devotion to that great object—the collection of a public library, which he opened during his lifetime, and in which he himself took his seat in the reading-room as one of the readers—inspires us with respect, and makes us regret that, according to the Polish historian Lelewel, his method of obtaining books was often seriously objectionable. "Some he bought," says Lelewel, "some he acquired by exchange, some he extorted, and some he obtained surreptitiously." The result of his long and patriotic labours was, that his great Polish library, with not more than five Russian books in it, was carried off to St. Petersburg. The best that can be said in extenuation of the act is, that in Poland itself the treatment of libraries was anything but exemplary. Lelewel relates that in the Jagellon library of the university of Cracow, during the Austrian occupation, about 1800, the sparrows built their nests in the piles of volumes, and that the librarian Przybylski called them his best assistant librarians, because they ate the insects. The principal present libraries on the Polish soil are, that of Lemberg, founded by Count Ossolinski, formerly director of the imperial library of Vienna; that of Posen, founded by Count Raczyński at his private expense for public use; and that of Cracow. Among Russian libraries, the imperial of St. Petersburg stands of course pre-eminent, and now enjoys the full sunshine of imperial favour. In the year 1852 the Emperor Nicolas bought for it in a mass the library of the academician Pogodin, for which the sum of 150,000 silver rubles, or 24,000*l.*, was given. The library having outgrown the building, a large extension of it has been ordered, and the works are in progress. Of the other libraries at St. Petersburg, that of the Academy of Sciences, and of the Rumiantsov Museum, founded by Count Rumiantsov, are the most important, the former containing a splendid collection of Oriental manuscripts, partly acquired by the successes of the Russian arms in Persia. Though Moscow possesses two libraries, one of the synod and another of the university, the deficiency of a public library is so much felt, that in 1859 the intention of founding one by subscription was under discussion. The libraries of Kazan, Kiev, and Kharkov are some of the most important of the provincial libraries, and a general activity respecting libraries now prevails in Russia, of which in a few years it may be expected to see the fruits.

England has been a country whose condition with regard to libraries was decidedly in arrear of its general condition with regard to learning and literature. For centuries its capital was without a public library; many of its towns and cities of a size and importance which would on the Continent ensure their possessing such an institution, are still without one. While in some localities libraries were so distressingly deficient, in others they were uselessly numerous. With no collection of books beyond subscription libraries of moderate extent at Newcastle or Liverpool, twenty or thirty were congregated at Oxford and Cambridge, where however they were never "introduced to each other," and drew no advantage from the proximity. One great objection existed to almost all the libraries of England—their inaccessibility in some cases, their too limited accessibility in general. A movement has now commenced in two directions: to collect in one locality a great monumental library, such as may give to our authors and investigators advantages they have never enjoyed, but which for the advancement of sound literature are really indispensable; and to scatter all over the country collections of respectability and value, so as to provide for residents in all parts reasonable access to sources of solid instruction. It is a great thing that so much should have been done in England without these appliances.

A separate article has been given in the English Cyclopædia to the

British Museum. No other collection in the metropolis is of so much importance as some in the provinces. The library of the London Institution in Finsbury Circus is an establishment at the head of a class, once promising to become more numerous than it ever became—the proprietary libraries, set on foot by a union of shareholders, who, in addition to the purchase of the share, contribute an annual subscription, which defrays the going-on expenses of the establishment. An enthusiasm for these valuable institutions was a pleasing feature at the commencement of the century; the Royal Institution, the London, the Russell, and the Surrey were established within a few years of each other, beginning with 1803. The library of the London Institution was formed with admirable taste and judgment by extensive purchases at the sales of the Marquis of Lansdowne and others in 1806 and subsequent years. As Professor Porson was the librarian, it may be supposed that German was not in the ascendant, but in other modern literatures—French, Spanish, Italian—the collection is much richer than usual. By a liberal regulation, each shareholder or proprietor is entitled to give admission to two readers; and the noble library-room of the London Institution, close to the city of London, but looking out on the trees and turf of the Circus, has been the scene in which the literary tastes and feelings of many a young fellow-citizen of Milton have been imbibed or strengthened. The library contains 60,000 volumes; but less money is annually expended on the books than on the lectures, which are one of the principal attractions in this as in most similar establishments. In the Royal Institution, founded before the London, in 1803, science has always been the most prominent feature; and from its Laboratory the discoveries of Davy and Faraday have emanated, to spread through Europe. The library is reported to contain about 26,000 volumes. The Russell Institution is an establishment of the same kind, but of less importance. Two others of the class, the Surrey and the Aldersgate Street Institutions, have, after some years of prosperity, sunk and disappeared, a lamentable proof that without permanent endowment such institutions are liable to dissolution as well as decay. Persons have been known to purchase shares in an association of this kind with the express purpose of proposing to break up the institution and divide the property, reckless of the detriment they might inflict on the literary prospects of coming generations. In cases where the original spirit survived in the body of the members, such proposals have been rejected with the indignation they deserve.

Many associations of this kind exist in the suburbs of London, at Islington and elsewhere; and the Mechanics' Institutions, which were originally founded at Glasgow, but introduced to London in 1823, may be regarded as a humbler form of the same kind of establishment. The "London Library," in St. James's Square, has a somewhat different character. The London Library is, in fact, a proprietary circulating library, while the London Institution and others of its class are proprietary reading-rooms. The libraries of the Clubs—another series of proprietary libraries—are in appearance some of the most splendid rooms in London, and are in some cases remarkable for the intrinsic value as well as for the fine condition of their volumes. The library of the Athenæum contains, for instance, a good collection of English history.

The libraries of the learned societies, and of the inns of court, are in many instances of considerable importance, and in some not exclusively of a professional or limited character. That of the Royal Society, lately removed to Burlington House, stands at the head, with 50,000 volumes. The Antiquarian, the Geographical, the Royal Asiatic, and the Linnean societies have collections which comprise many valuable works, but which, in some cases, are almost wholly made up of donations or exchanges, and it would be vain under those circumstances to expect completeness. The libraries of the inns of court are differently situated, and more than one of them has lately been the object of liberal expenditure. The library of Lincoln's Inn, is the oldest in London, its foundation dating from 1497, but the noble edifice in which it stands was only erected in 1845, on what was formerly a portion of the gardens. It has been made the repository of a greatly extended collection of books, not only of English, but of American, colonial, and foreign law, amounting, when Mr. Spilsbury the librarian published an account of it in 1856, to 27,000 printed books and 700 manuscripts. A new building is now erecting for the library of the Middle Temple, rendered necessary by the recent enlargement of the collection. There are two libraries in London chiefly intended for the clerical profession, but of a more public character than most of those which have been enumerated. The library of Sion College, in London Wall, of which all the incumbents of benefices in the city of London are fellows, was founded as far back as 1630, when, on the Rev. John White building a row of almshouses on the usual one-story plan, it struck one of his friends that the space above them, otherwise thrown away, would afford an excellent opportunity for building a library, without any expense for ground, and the notion was carried out. The collection is said to amount to 40,000 volumes, and admission can be granted by any Fellow of the college or by the librarian. The Dissenters' library, in Redcross Street, founded by Dr. Williams, is of about half the number of volumes and of still more easy access.

The "administrative" libraries of London are not prominent. The libraries of the Houses of Lords and Commons, both in the new Houses of Parliament, but entirely distinct, are of recent formation; the

former libraries having been destroyed at the conflagration of 1834. The library of the East India House has been already spoken of. It is the most important collection of the kind in London.

Of libraries not in the capital, the Bodleian of Oxford is the most extensive and the most interesting. Long the first collection in England, it still remains the second and is likely long to remain so. Increased interest in its prosperity has been manifested in the present century, during which it has received the valuable presents of the Gough, the Malone, and the Douce collections, each of them more important than any single donation in the 18th century, and only to be paralleled by the benefactions of the Lauds and Seldens of the 17th. Its venerable buildings, so appropriate to a university library, are now becoming inadequate to the reception of its treasures, and a proposal has been recently decided on which will at once provide the establishment with room and increase its magnificence. The Radcliffe Library building, in almost immediate juxtaposition to the Bodleian Library, and remarkable for the beauty of its interior as well as exterior structure, is to be added as a reading-room to the Bodleian, with which it will be connected by a passage, and the Radcliffe collection is to be removed elsewhere. This will be singularly in accordance with the intentions of the founder, Dr. Radcliffe, the great physician, who originally intended to enlarge the Bodleian Library, by building another room connected with it; a scheme which only failed on account of some conditions insisted on by Exeter College. The Radcliffe and the Bodleian Libraries have been remarkable among libraries in close juxtaposition for having come to an agreement which would have been thought likely to suggest itself to almost all libraries in a similar predicament. The Radcliffe has confined itself to the purchase of books in a particular department—natural history—and the Bodleian has avoided making purchases in that department. Had a similar plan been followed with regard to college libraries, and Hebrew or Arabic manuscripts, for instance, been as systematically collected at one, as Welsh manuscripts have accidentally been at another,—at Jesus College—the large assemblages of books at Oxford might have constituted one all-embracing library. The Bodleian library consisted, in 1849, of 220,000 volumes as returned to the House of Commons, and may be now estimated to amount to 250,000. There are several minor libraries belonging to the University—the Radcliffe, the Ashmolean, the library of the Taylor Institution for modern languages, &c. The college libraries are, however, the distinguishing glory of Oxford. Within a short walk of each other, in a city of not more than 30,000 inhabitants are found a range of some of the most splendid edifices ever erected for the reception of literature, most of them enclosed with lawns and gardens, some venerable for antiquity, some radiant with architectural splendour. Christ Church and All Souls are particularly magnificent, Merton is venerable; but almost all have striking attractions, and each of many would be a gem elsewhere. The same may be said of Cambridge, where, indeed, the arrangement of the buildings is superior to that at Oxford, and one range of gardens with noble trees joins on to another, leading along the banks of the Cam, from college to college, from library to library. By perhaps an intentional arrangement of Sir Christopher Wren, who built the noble library at Trinity College, Cambridge—the place of education of Bacon, Newton, and Byron, of Tennyson, Thackeray, and Macaulay—the windows are so high that the view of this unrivalled scholastic landscape which they command is not allowed to distract the reader from study. The library so lodged, which now contains about 50,000 volumes, embraces the autograph of Milton's *Comus*, the Shakespere collection of Capel, and the German library of Archdeacon Hare. The library of St. John's is, like the college, a rival to Trinity; Bennet's is famous for its Anglo-Saxon manuscripts; that of Magdalen for the autograph of Pepys's Diary and the Pepys collection of ballads. Other libraries have other claims to attention, while the University Library, placed in the new and splendid room, erected by Mr. Cockerel, which is only a portion of the intended design, forms a worthier rival than is supposed to the Bodleian. The collection of about 30,000 volumes, brought together by Bishop Moore of Norwich, and presented to the University by George I., abounds in resources not yet sufficiently explored. The library is spoken of in the University Calendar as containing over 170,000 volumes. The Fitzwilliam library also belonging to the University, and placed in the Fitzwilliam Museum, of which it forms a part, is rich in works of art.

Manchester was long distinguished among English towns—as it is now among English cities—by its possession of a library to which access was as free as to any of the libraries of the continent. It was founded in 1653 by the will of Humphrey Chetham, of Manchester, whose family motto was not of a very liberal cast, "*Quod tuum tene*," "*Keep what is thine*." There can hardly be a more striking contrast than that between the low narrow and crowded rooms in the building of Chetham's hospital, where this collection, chiefly of ancient folios, is now, it is true, accessible to the student, but seldom disturbed, and the fine airy lofty rooms, full of modern books in splendid bindings, which house the "Free Library" of Manchester, founded in 1850, within an easy walk of it. The Manchester library was the first established under the Free Library Act of 1850, which gave power for limited local rates to be levied for the establishment of a free and public library, on the consent obtained of two-thirds of a meeting of the rate-payers. The Americans had already anticipated us by a

similar law, but the English Libraries Act may be considered as only an extension of the Museums Act of 1845. The early history of the Manchester library is set forth in the reports of Mr. Edward Edwards, its first librarian, whose exertions are understood to have had a considerable share in promoting and obtaining the Act of Parliament. Free libraries have since been proposed and adopted in many localities, and rejected in others—one has been rejected in London, and one has been founded in Oxford, adding to that city of libraries one collection more. At Liverpool a great example of munificence has been set by Mr. Brown, a Liverpool merchant, trading with America. The Free Library, founded in 1852, having grown so rapidly as to require an extension of room, he presented the town with a new and spacious library building at his own expense, of which the estimated cost was 25,000*l*. A connection has been proposed to be established in some cases between old establishments and the new—such as the Chetham and the Free—and this would certainly be one way of revivifying the old cathedral libraries, of which Mr. Beriah Botfield's volume on that subject has shown that they possess more valuable collections than they have always had credit for.

In Scotland, the largest collection is the Advocates' Library, at Edinburgh, belonging to the Faculty of Advocates, and located close to the Courts of Law, in immediate proximity to, and under the same roof with, the library of the Writers to the Signet. The Advocates' Library formerly occupied the identical room now occupied by that of the Writers, and some passages of law have, it is understood, taken place between the two branches of the profession respecting their rights to light, which is so deficient, that in some underground rooms of the Advocates' Library candles are used at noon-day. The present Signet library is a palatial room, which reminds the visitor by its appearance of the libraries of the London clubs. The Advocates and the Signet libraries together—the former about 180,000 volumes, and the latter about 50,000—amount to nearly a quarter of a million volumes, and if an arrangement had been come to similar to that between the Bodleian and Radcliffe libraries, Edinburgh might have reaped a material benefit. The Advocates' library contains a large Spanish collection, formerly belonging to the Marquis of Astorga, and acquired in a mass from Mr. Thorpe, the London bookseller, but found, after purchase, to be much less choice than was expected. It has also a collection of works relating to the Scandinavian nations, bought like a similar one in the British Museum of Professor Thorkelin, and a mass of 100,000 foreign dissertations bought at the recommendation of Sir William Hamilton for 80*l*. Though both the Advocates and the Signet library are rich in law, yet neither is by any means exclusively a professional library, and neither is pre-eminently Scottish, though of course, Scottish publications predominate more than elsewhere. The library of the University of Edinburgh occupies the finest room in Scotland and one of the finest in Great Britain. The collection has upwards of 100,000 volumes, but is said to be very deficient in some branches of learning. The leading collections in provincial Scotland are those of the universities—Glasgow, St. Andrews, and Aberdeen. They were long an object of odium to English booksellers, on account of the privilege that had been somewhat liberally granted to them of demanding a copy of every book published. This right was exercised in very unequal degrees, for when it was abolished in 1835, and compensation granted in proportion to the actual loss sustained, Aberdeen was ordered to receive only 320*l*. a-year from the Consolidated Fund, while Glasgow was rewarded for its diligence with 707*l*. Glasgow, in addition to its fine university library, has that of the Hunterian Museum, founded by Dr. Hunter, of London.

There is probably no more singular origin of a library on record than that of Trinity College library in Dublin. The English army, which had defeated some Irish insurgents and their Spanish allies at the battle of Kinsale, on Christmas Eve, 1601, resolved to "do some worthy act that might be a memorial of the due respect they had for true religion and learning." For this purpose, the soldiers raised among themselves 1800*l*. to furnish a library for the University of Dublin, then recently founded. Their agents coming to London for that purpose, found Sir Thomas Bodley engaged in making purchases for his intended library at Oxford, and conferred with him on the choice of books. In 1656, the death of Archbishop Ussher brought his valuable library into the market, and again "the soldiers and officers of the then army in Ireland, out of emulation to the former noble action of Queen Elizabeth's army, were incited by some men of public spirit to the like performance," and the archbishop's library was bought by the army and presented to Trinity College, with the sanction of Oliver Cromwell. The most important addition ever made to it at one time, was that of the Fagel collection, formed by several generations of the Fagel family in Holland, and amounting to nearly 18,000 volumes, which were acquired for 10,000*l*. Some valuable books were bequeathed by a Mr. Quin, but under such onerous conditions that Mr. Panizzi, who had to cross the sea for the purpose of examining an Ariosto of the collection for his edition of the '*Orlando*,' complains loudly of the illiberal restrictions by which the donor had rendered it impossible to receive his benefits with unmixed feelings of gratitude. The Trinity College collection was counted in 1848, and found then to contain 101,962 volumes of printed books, and 1512 of manuscripts. Marsh's library, of about 5000 volumes, founded at Dublin in 1707, by Archbishop Narcissus

Marsh, who died in 1713, is said to be the most easily accessible of any in Ireland, but the applicant for admission is required to produce a voucher of his respectability. An Act of Parliament was passed in 1854 authorising its transfer to a new building to be erected in Dublin as a National Gallery and Museum. The libraries of the Royal Hibernian Academy, the Dublin Society, and the King's Inns, or Inns of Court, are the most prominent remaining collections of the Irish capital. The library of St. Patrick's College, Maynooth, is rising into importance, and those of the new Queen's Colleges in various parts of Ireland will in some cases form new literary centres of extensive districts.

Of the libraries of America, in general, Mr. Rhees' 'Manual of Public Libraries,' amid a large quantity of uninteresting particulars of insignificant institutions, contains some striking statistics. There are now, it appears, twenty-five libraries in the United States which contain each more than 20,000 volumes, the whole number in the twenty-five being 979,902, or little short of a million. The State of New York contains six of these; the State of Massachusetts five; and there are also five in the district of Columbia, or Washington and the country immediately adjoining. In the libraries of the United States the proportion of foreign books is in general small. Of all the libraries from which reports have been received by Mr. Rhees, the one that has the largest collection in French has 4000 volumes; the largest collection in German 6000; and the largest in Spanish, which is in California, 596. It is probable, however, from this statement, that Mr. Rhees has received no report from some of the principal libraries of the great cities. The history of some of these presents many points of interest. The library at Harvard College, at Cambridge, near Boston, which was for more than two hundred years the largest and most valuable in the United States, was founded in 1638, and received the benefactions of some of the early contributors to the Bodleian, Sir Kenelm Digby included. It had increased to 6000 volumes, of which a catalogue had been published, when it was totally destroyed by a fire in 1764. The legislature of Massachusetts was then in session at Harvard Hall, and voted immediately 2000*l.* to erect a new building. Subscriptions soon flowed in to reinstate the library, and Thomas Hollis, of London, signalled himself by his liberality, which was continued by members of his family till the donations amounted to 6000*l.*, currency of Massachusetts. Among the English donors to the collection occurs the name of Mr. Thomas Grenville, who gave 100*l.* in 1846. The only fixed income of the library to this day, is what is called the Hollis and Shapleigh Fund, amounting to about 450 dollars a year, but the deficiency is made up by munificent though irregular donations. The library counted in 1858, when Mr. Guild's 'Librarian's Manual' was published, 75,000 volumes in the main library, placed in a building called Gore Hall. If other collections were included, such as the University Medical Library of 2000 volumes, kept some miles off at the Medical College in Boston, the total would amount to 116,000, and if the society libraries of the students were added, the whole would be 128,000. The libraries of Yale College, at Newhaven in Connecticut, and of Brown University, at Providence in Rhode Island, number respectively 35,000 and 28,000 volumes. The collection of the Library Company at Philadelphia, is especially interesting as being that into which the few books have grown which were originally brought together in 1731, by a few youths, chiefly artificers, at the suggestion of Benjamin Franklin. It occupies in 1860 a separate building, erected so long ago as 1789, and of which Mr. Guild remarks, "the style of architecture is of course somewhat antique." The edifice is adorned, over the principal door, with a statue of Franklin, executed in Italy by Lazzarini, and the first specimen of sculpture, of life size, ever imported into the United States. It contains 60,000 volumes, and with it is kept under the same roof the collection of Mr. Logan, Franklin's early patron, amounting to 10,000 volumes more. Washington, as the official capital of the United States, is the place at which some of its most important libraries are assembled. The library of Congress has been twice destroyed by fire, once by the British army in 1814, as an act of vengeance for the destruction by the Americans of the House of Assembly of Upper Canada; and the second time by accident on the 24th of December, 1851. Fortunately on the former occasion only 3000 volumes perished, in the latter but 20,000 volumes were saved out of 55,000. The library has in consequence been rebuilt entirely of iron, — floor, roof, pillars, staircases, and shelves. The collection was estimated in 1858 to amount to 63,000 volumes. Of the State libraries of America, that of New York, kept at Albany, and amounting in 1858 to 52,000 volumes, is the most extensive. The Astor Library, already mentioned, was opened at New York in 1854, with 70,000 volumes, chiefly collected by Dr. Cogswell, the librarian, in three visits to Europe in preceding years; and in 1855, Mr. William Astor, the son of the founder, declared his intention of building, at his own expense, another gallery by the side of the former, to contain an additional 100,000 volumes. The Boston Athenæum, a proprietary library, which had been founded in 1806, on the plan, it was said, of the London Institution, had, in 1858, attained to a position surpassing that of its prototype, if the number of books be correctly stated at 70,000. This was the leading library of Boston till the legislature of Massachusetts authorised the levying of rates for the formation of an entirely free library. Mr. Bates, a native of Boston, but carrying on

business as a merchant in London, wrote in 1852 to offer a donation of 50,000 dollars towards the purchase of books; and in 1855, as soon as he received information that the building was actually commenced, he sent a donation of another 50,000 dollars for the same purpose. Other citizens contributed collections of books, some of 10,000 dollars, &c.; and on the 1st of January, 1858, the new building was opened with appropriate ceremonies, and Boston found itself in possession of a public library of 65,000 volumes. An American banker in London, Mr. George Peabody, is the founder of two institutions in the United States comprising public libraries. 'The Peabody Institute' of Danvers, and 'the Peabody Institute' of Baltimore. The principal defect of the present great movement in America, is the want of concentration. It is evident from the spirit that has shown itself among its merchant princes, that it will soon be in possession of several libraries of the third, and probably of some of the second, order; but there is as yet no indication of its being speedily endowed with one of the first, a great central collection. Amid the difficulties presented by the rivalry of different states, the most feasible plan of effecting this great object, an object more important to the scholarship and intellectual progress of the country, than the foundation of an additional twenty thousand common school libraries, appeared to be that advocated by Professor Jewett, of applying to the formation of such a library part of the funds of the Smithsonian Institute, founded by Congress at Washington from the bequest of Mr. Smithson, an Englishman. The scheme was sanctioned by Congress, but its actual execution seems to have depended on the personal influence of the Professor, and it was at once abandoned when by the proceedings of another Professor he was compelled to resign. The Smithsonian library, now a collection of about 25,000 volumes, has forfeited, at the request of its own officers, the right of receiving a copy of all books published in America; and is for the future to be confined almost entirely to works of science. In America, as in Europe, the failure or success of projects of great public importance seems to be often viewed with indifference by the great body of the public, and to depend almost entirely on the presence or absence of particular individuals of some force of character.

In Upper Canada a system with regard to public libraries has been introduced analogous to that prevailing in England with regard to national schools. If a fund be raised by a corporation for the foundation of a library, it may apply to the council of public instruction, and select books from a list sanctioned by the council, to the value of the money raised. The council in return sends back not only these books, but a number of other volumes of equal money value selected by the council itself. This system, which is that of the Rev. Egerton Ryerson, is considered by many Americans superior to that which prevails in the United States. Three hundred and twenty-six libraries in Upper Canada have been founded on this plan, in connection with schools and otherwise. The largest libraries in the country are one of about 6000 volumes at Hamilton, and one of 7000 at the University of Toronto. The library of the Legislature, at present at Toronto, is an excellent collection, of which a good catalogue has been published. The collections in Lower Canada are of a different cast, the most important being those of the old Jesuit colleges. The largest library in the British Colonies is probably the Public Library of the Cape of Good Hope, at Cape Town, of more than 30,000 volumes.

In Australia, the new library at Melbourne, which already contains 25,000 volumes, is conspicuous also for the number of its readers, which in last year amounted to 77,000, more than half the number of those in the same period at the British Museum. These facts in the recent history of libraries in the colonies and offspring of England, are remarkable in a high degree, and there is quite enough to justify the inference we have drawn that a new era in the history of libraries is approaching.

A brief notice of the best sources of information on the subject will conclude this article. On the history of individual libraries, a whole library has been written. The mere titles of books on the subject, with references to notices in other books, fill up five hundred and forty octavo pages in Vogel's 'Literatur öffentlicher Bibliotheken,' a valuable compilation, which is intended as a guide to all the printed information in existence on the public and corporation libraries in Europe, and also on the private libraries, no small number, which have subsequently become a portion of public ones. The volume was published in Leipzig in 1840, and in the same year Dr. Petzholdt commenced the issue of his bibliographical periodical 'Anzeiger für Literatur der Bibliothekswissenschaft,' which in addition to the titles, contains short critical notices of catalogues, reports, and other books relating to libraries. It is compiled with German diligence, but whether from the dearth of English books, or from some other cause, is not quite so full on the English literature of the subject as might be desirable. Another periodical, the 'Serapeum' of Dr. Naumann, published at Leipzig also since 1840, gives articles on libraries, and copies of their regulations, and also contains what is called a chronicle of libraries, in which are recorded the deaths and promotions in the little "bibliothecal" world, a branch of information which is also kept in view by Dr. Petzholdt. Some years ago there was published in England a book called the 'Encyclopædia of Literary and Typographical Anecdote,' by a printer of the name of Timperley, and though the compiler did little more in many cases than bring together in order of date, cuttings from the newspapers and magazines, relating

to booksellers and printers, the volume is one that could much less easily be spared than many of higher pretensions; and keeps a place on the shelves of those who are fond of anecdote and the bye-ways of information, side by side with Hone's 'Every Day Book.' A volume on libraries on the same easy plan as Timperley's on printing, would be a very acceptable addition to our literature. The only separate book on the subject at present, is Mr. Edwards's 'Memoirs on Libraries' 2 vols., 1859, a work more ambitious but less useful, and less attractive, and in which it is remarkable how little the writer gives from personal observation, and how much from printed statements of mere detail, even in cases such as those of the history of the libraries of London and Manchester, in which both sources of information must have been open to him. With all their deficiencies, however, these volumes are, till some similar work shall supersede them, an indispensable companion to the inquirer into the history and statistics of libraries.

LIBRATION, a balancing motion, in which there is a position on one side and the other of which a body vibrates; being in fact the same in meaning as oscillation. This term is however particularly applied to a small irregularity, compounded of the moon's rotation round her axis and her orbital motion, by means of which her visible hemisphere is not always quite the same.

The mean revolution of the moon round her axis is the same period of time as her mean revolution in her orbit. If both motions were equable the moon would always present the same face to a spectator placed at the centre of the earth, on condition that the plane of her equator passed through the centre of the earth. None of these conditions being exactly fulfilled, and the variations being small and periodic, the consequence is that a small portion of the moon's surface in the eastern and western edges, and also in the northern and southern, is alternately visible and invisible. There is perhaps no subject in astronomy so difficult to explain to a reader who is not familiar with solid geometry; and the subject is not of sufficient importance to deserve any detail of illustration.

LICENTIATE IN MEDICINE. [PHYSICIANS, COLLEGE OF.]

LICHENIC ACID, a name given by Pfaff to an acid extracted by him from Iceland moss, but which has since been proved to be identical with fumaric acid. [FUMARIC ACID.]

LICHENIN ($C_{12}O_{10}H_{10}$), is a variety of starch found in the *Lichen islandicus*, or Iceland moss. It is colourless and tasteless, swelling up into a jelly-like mass in cold water, and dissolving in hot. Its solution is not coloured blue by iodine. It is converted into sugar by diluted and boiling sulphuric acid. Hot dilute nitric acid converts it into oxalic acid.

LICHENS, *Colouring matters of*. The lichens or *liverworts*, as they are frequently termed, constitute a large class of perennial plants. They are common in nearly all countries, growing on rocks, stones, trunks of trees, &c., and in appearance are very insignificant. They vary considerably in colour and size, but generally so much resemble the bark or earth to which they are attached, and over which they spread, that a somewhat close inspection is necessary before they are observed. Unimportant as they appear to be, however, it is greatly to their agency that we owe those magnificent lilac, blue, violet, purple, and many intermediate and compound colours with which wool and silk are dyed.

The English lichens are not much used for the manufacture of dyes, though were a system for their collection organised, it would probably be found that many varieties might be economically employed. Foreign lichens to the extent of 90,000*l.* worth are annually imported into this country from the south of Europe and west coast of America, but chiefly from the Canary Islands. They are principally collected from rocks in the neighbourhood of the sea.

Lichens do not contain in their natural state any colouring matter ready formed, but under the influence of air, water, ammonia, and a moderate temperature, certain acids and a neutral body existing in them are converted into a deep richly-coloured substance called *orcein*. Orcein is the dark purple or red matter that is finally produced under the above circumstances, but its formation is sufficiently gradual to admit of the process being arrested at any desired stage, and the tint if not the actual colour of the product thus varied at will. On these conditions, and on the dexterous mixture of the products with each other depends the shade of the resulting pigment, and not on the use of any particular variety of lichen. A skilful manufacturer will produce a given colour from any or all of the lichens, his only anxiety being to use that variety which contains the largest per-centage of colorific material.

The lichen colours are sent out by the maker either in the dry state, lump or powder, as a strong solution, or as a paste, conditions severally best suited to the uses to which they are applied. The details necessary to be observed in the production of these various forms of the colour are given in the respective articles on each. See ARCHIL; CUDBEAR; LITMUS.

Estimation of the value of lichens.—Lichens vary considerably in the amount of colour-producing substance contained in them. The following process, proposed by Stenhouse, is very easy of application, and gives accurate relative results. It is founded on the reaction of chloride of lime upon the colorific agent, a fugitive red colour being thereby produced. A given weight of the lichen reduced to powder in a mortar,

or to a pulp with water, is digested in thin milk of lime, and the mixture filtered; a standard solution of chloride of lime is now added in small quantities at a time, fresh portions being poured in as soon as the red colour produced by the previous portion has disappeared, the addition being discontinued when no more colour is produced. The relative value of several samples can thus be very quickly determined, or the strength of the standard solution being known, the absolute amount of colouring matter is clearly indicated.

As already stated, orcein is the colouring substance ultimately resulting from the treatment of lichens for the preparation of archil, &c. Now the body from which orcein is derived is a colourless matter, named *orcein*. Orcein exists ready formed in some of the lichens, but its chief source is certain acid matters contained in all varieties of the plant. Under the influence of alkalies these acids are converted into orcein, and into secondary acids. The primary lichen acids admit of being readily extracted, and Stenhouse has proposed that the operation be performed upon the lichens as soon as gathered, the storage, freightage, &c., of a great quantity of useless material being thereby obviated. The process recommended by that chemist consists in placing the lichens in wooden barrels, which are to be filled up with water containing a quantity of slaked lime, allowing the whole to stand a short time, then drawing off the liquor and saturating it with common hydrochloric acid. In this way the lichen acids are dissolved out by the lime, but are re-precipitated by the hydrochloric acid, and after collecting on a filter may be drained, dried, and packed in casks for transit. This proposal, however, has not been adopted, or if adopted has not been persisted in; perhaps the ready-formed orcein occurs to a larger extent in the lichens than has been supposed, and not being precipitated from solution by hydrochloric acid, would be lost if the whole lichen were not acted upon.

A rough assay of lichens for colouring matter may be made by going through the above process on the small scale, a known weight of the lichen being taken, and the precipitated acids being dried at 212° Fahr. and weighed.

A list of the lichens used in the production of pigments, and a woodcut illustrating their general appearance, will be found under LICHENS, in NAT. HIST. DIV.

The acid and other bodies derived from the lichens are numerous, and as a whole have formed the subject of elaborate investigations by Stenhouse and Schunck. Their relations to each other, however, are at present not very well ascertained; and although Gerhardt has proposed formulæ calculated from the analyses and the provisional empirical formulæ given by the chemists who have examined them, he admits that those formulæ still require verification, and indicates that fact by placing a note of interrogation after the formulæ.

The following is a list of the lichen derivatives:—

1. Chrysophanic acid $C_{20}H_8O_6$ (?)
2. Usnic acid $C_{18}H_{16}O_{14}$ (?)
3. Erythric acid $C_{32}H_{16}O_{16}$ (?)
4. Erythrellic acid.
5. Picroerythrin $C_{30}H_{20}O_{16}$ (?)
6. Erythro-mannite $C_{14}H_{16}O_{12} + Aq.$ (?)
7. Nitro-erythro-mannite $C_{14}H_{10}(NO_4)_6O_{12}$ (?)
8. Lecanoric acid $C_{32}H_{14}O_{14}$ (?)
9. Orsellic acid $C_{16}H_8O_8$ (?)
10. Pseuderythrin $C_{16}H_7(C_4H_5)O_8$
11. Amarythrin.
12. Telerythrin $C_{14}H_6O_{12}$ (?)
13. Parellie acid $C_{18}H_6O_8$ (?)
14. Roccellinin $C_{36}H_{16}O_{14}$ (?)
15. Evernic acid $C_{34}H_{16}O_{14}$ (?)
16. Gyrophoric acid.
17. Everninic acid $C_{18}H_{10}O_8$ (?)
18. Orcein $C_{14}H_8O_4 + 2 Aq.$
19. Orcein $C_{14}H_7NO_8$ (?)
20. Leucorcein.
21. Chlororcein.
22. Azoerythrin.
23. Erythroleic acid (erythrolein?)
24. Litmic acid (azolitmin?)
25. Litmylic acid (erythrolitmin?)
26. Spaniolitmin.
27. Beta-orcein $C_{16}H_{10}O_4$

1. *Chrysophanic acid*; *Vulpinic acid*.—This acid is contained in wolves' lichen (*Evernia vulpina*), in yellow moss (*Parmelia parietina*), as well as in the different varieties of rhubarb. [CHRY SOPH ANIC ACID.]

2. *Usnic acid*; *Usnein*; *Parietin*.—This body is obtained on treating the Jupiter's-beard, Tree-beard, and other hair-like members of the *Usnea* genus of lichens, with thin milk of lime, in the manner already described. The precipitated acid may be obtained in crystals from solution in warm (but not boiling) alcohol. Alkalies convert it into

beta-orcin. One equivalent of hydrogen in usnic acid may be replaced by one of a metal, and *usnates* formed.

3. *Erythric acid* and its derivatives, 4, 5, 6, and 7, will be found described in a separate article. [ERYTHRIC ACID.] It exists in large quantity in many lichens, and is therefore of more importance than some other of the lichen acids.

8. *Lecanoric Acid*; *Lecanorin*.—This acid may be extracted from the *Roccella tinctoria* and *Lecanora tartarea*, in the same way as described for usnic acid, or by direct treatment of the lichen with ether and evaporation of the ethereal liquid. It crystallises in star-like groups of needles. By long boiling with alkalis, or with lime, lecanoric acid is converted into carbonic acid and orcin; but if ebullition be continued for a short time only, the acid assimilates two equivalents of water, and a new acid is formed, to which the name *orsellic* or *orsellecic acid* (9) has been given. *Lecanorates* and *orsellates* have a constitution similar to the usnates. The orsellate of ethyl is formed when lecanoric acid is boiled for some time in alcohol; it crystallises in plates or needles, and when first discovered was called *pseuderythrin* (10). *Amarythrin* (11) is a non-crystalline substance resulting from the action of air upon orsellate of ethyl. When exposed for many months to the air, it is changed into a granular body, (12) *telerythrin*.

Alpha-orsellic acid, and *beta-orsellic acid*, were obtained by Stenhouse from the *Roccella tinctoria*; but their composition and properties are so similar, that Gerhardt thinks them identical, and notices them as ecanoric acid.

13. *Parellic acid*, *Parellin*, is described by Schunk as being met with in the preparation of lecanoric acid. It is slightly soluble in water, and very soluble in alcohol or ether. By slow evaporation it is obtained in colourless, brilliant, and heavy needles. Boiling alcohol does not act upon it, as upon lecanoric or erythric acids, and on this fact depends its isolation and purification. It forms *parellates* with bases.

14. *Roccellinin* is also contained in the *Roccella tinctoria*. It very much resembles parellic acid, but appears to be insoluble in water.

15. *Evernic acid* is obtained in the usual manner from *Everina prunastri*, or *Sachet lichen*. It may be crystallised from alcohol, and forms *evernates* with bases. *Gyrophoric acid* (16), from the *Gyrophora pustulata*, was first described by Stenhouse, but, according to Gerhardt, is either evernic or lecanoric acid.

17. *Evernic acid*, *Evernesic acid*, is a product of the action of alkalis on evernic acid, orcin being at the same time formed, possibly according to the following equation:—

When deposited from alcohol it forms silky crystals. It is isomeric with veratric acid. It forms *everninates*.

18. *Orcin* and its derivatives, *chlororcin* and *bromorcin*, will be found described in a separate article. [ORCIN.]

19. *Orcein* is the colouring matter that results from the action of air and ammonia upon the principles contained in lichens. Its immediate source is orcin, under which name it will be found more fully described [ORCIN], together with its derivatives *leucorcein* (20) and *chlororcein* (21).

22. *Azoerythrin* and *erythroleic acid* (23) are substances associated with and very analogous to, if not identical with, orcin.

24. *Litmic acid*.—The matter known in commerce as *litmus* differs only from orchil and cudbear in being formed with the additional aid of carbonate of potash. According to Kane, litmus contains *litmic acid*, at first called *azolitmin*, soluble in water, slightly soluble in alcohol, insoluble in ether; *litmylic acid* (25), (*erythrolitmin*), very soluble in water, and but slightly soluble in alcohol or ether; and *spaniolitmin* (26), an indefinite, non-azotised body.

27. *Beta-orcin*.—Usnic acid differs from all the acids of other lichens in not furnishing ordinary orcin when treated with alkalis, but a homologue of that substance called *beta-orcin*. Beta-orcin is, however, best prepared by submitting usnic acid to dry distillation, treating the distillate with water, and evaporating to crystallisation. It may be purified by treatment with animal charcoal and recrystallisation from weak alcohol.

Beta-orcin occurs in large lustrous crystals of slightly sweet taste. It is less soluble in cold water than orcin is, but is very soluble in boiling water, in alcohol, or in ether. When heated it sublimes. With ammonia it gives a dark red colour, and with chloride of lime a blood-red.

LICHENSTEARIC ACID ($\text{C}_{28}\text{H}_{44}\text{O}_6$), a peculiar oily acid contained in Iceland moss. It forms small colourless crystals, inodorous, and possessing a bitter rancid taste, insoluble in water, but freely soluble in alcohol and ether. It is a very feeble acid, forming with the alkalis salts which resemble soap in their character.

LICKS, as they are called in North America, are small tracts of land with a sandy soil, on which salt crystallises in the form of an efflorescence, and which are resorted to by all animals that feed on grass, for the purpose of licking up the salt. They are of great importance in Brazil, where they are called *Carreiros*. The herds of cattle are there very large, and sometimes amount to nearly 50,000 head. These cattle grow lean and are reduced to bad condition if

they cannot from time to time get salt, which they lick with great eagerness. When a cattle estate has no natural licks, the proprietor is put to considerable expense to provide the necessary quantity of salt for his cattle. Hence the value of a large estate is greatly enhanced by the possession of one or more licks, though in general they hardly occupy a space twenty paces long and wide. Wild animals, as deer, buffaloes, wild hogs, &c., also resort to them.

LICTOR, a public officer who attended on the principal Roman magistrates. This office is said to have been derived by Romulus from the Etruscans. ('Liv.' i. 8.) The kings, and afterwards the consuls, were attended by twelve lictors, the dictator by twenty-four, and the master of the horse by six. The lictors went before the magistrates one by one in a line; he who went first was called *primus lictor*, and the one who immediately preceded the magistrate *proximus lictor*.

The lictors were originally chosen from the *plebs* ('Liv.' ii. 55); but in the time of Tacitus they appear generally to have been freedmen ('Ann.' xiii. 27), probably of the magistrate on whom they attended.

The duty of the lictor was to see that proper respect was paid to the magistrates, and to inflict punishment on those who were condemned; and probably to assist in some cases in the execution of a decree or judgment in a civil suit.

The lictors carried on their shoulders rods bound in the form of a bundle, with an axe in the middle.

The etymology of the name is doubtful. 'Gellius' (xii. 3) derives it from the verb *ligare*, because the lictor had to bind the hands and feet of criminals before they were punished.

LIEN, at common law, in respect of personal chattels, is the right in one man legally possessed of the chattels of another, to retain the same until certain present claims of the holder against the owner are satisfied. Liens are general or specific; they are implied by law, or authorised by custom or usage; or they are created by express contract between the parties. Their existence is conditional on possession, not wrongfully obtained, and uninterruptedly continued. And their purpose is, in the way of a natural remedy, to enforce simple rights, such as accrue chiefly in commerce, and such as in point of principle are too plain and obvious to admit of dispute.

For instance, upon a sale, for ready money, of a specific chattel, the right of property in the article and the right of possession immediately pass by the law of this country to the purchaser; but until the vendor actually or constructively parts with possession of the thing sold, he has a right to retain it for the price agreed to be paid, and that right is called his lien. This is one instance of a lien implied by law. The varieties of this kind of lien are numerous. As a general rule, every mechanic may retain a chattel for the price of his labour in improving it at the request of the owner. A dyer, a fuller, a packer, a tailor, who employs his labour on goods sent to him for the purpose, are familiar instances of a very extensive class. A common carrier may retain the merchandise till the carriage is paid; and an innkeeper the goods of his guest for the amount of his bill; and in both instances this is deemed a fair privilege of those persons at common law who are obliged by the same law to receive the goods or guests respectively, whenever it is not unreasonable that they should do so. But in respect of ships chartered for a particular voyage, if it should be said they do not come within the definition of carriers at common law, there is still a lien, for the freight, on the goods carried, in virtue of the improved value assumed to have been conferred thereon by their conveyance to a different market. As between attorney and client, the former has a lien on all papers in his possession for the amount of his bill; as between principal and factor, there is a lien in the latter upon all goods in his possession belonging to the former, for his commission and any advances which he is under to the principal.

Lien, where not implied by law, may exist by custom. But custom in this, as in all other cases, to be legal must be reasonable, and not repugnant to the main purpose of the parties in the transaction which it is to affect. There is no lien, by law, for the agistment of cattle; but to set up a lien by custom in the case of milch cows would obviously defeat the purpose of both parties, as the owner must have possession of them in order to milk them from time to time. The training of a race-horse offers a similar illustration, since it is assumed that the owner means to enter him for different races, and must obtain possession in order to put him on the course.

As, however, it is quite competent for the parties to create a lien by their own agreement, if they are foolish enough to enter into a contract which it is either difficult or inconvenient, or even impossible to perform, the contract is good, notwithstanding, and the sufferer must take the consequences.

A general lien is a right to retain the particular goods until all the holder's claims accrued against the owner in the same course of business are satisfied. Such a lien is implied by law in favour of a factor for his general balance of commission and advances due from the same principal. Usually, however, a lien of this nature is not favoured by the law; and even where it exists by custom, as in the case of a carrier for his general account against the same consignee, the consignor may stop the particular goods *in transitu*, and obtain possession on payment of the carrier's charge in respect of them only. A specific lien, as the latter illustration may suggest, is a right to retain particular goods for claims, in respect of such goods only; it is

more favoured, because less prejudicial to the interests and course of commerce.

Lien, as known to the common law, is conditional on possession of the goods being in the same hands as the right of lien. It ceases to exist the moment that possession is parted with. And though possession may have been lost unawares, the lien cannot be revived by getting possession again. Possession must be actual; but the loss of it may be constructive. If goods in the hands of a wharfinger be transferred to another name in the wharfinger's books, though not removed from their place in the warehouse, the previous holder thereby loses his lien. Or if he who has the lien procures them to be taken in execution at his own suit, or ships them for his principal on his account and risk, the lien is gone past recovery.

The possession must have been fair and legal in its commencement for any lien ever to attach. For if fraud or a trick be used to obtain possession, or otherwise it commences wrongfully, the object being to gain a lien, that object is thereby effectually frustrated.

The foundation of lien must be a present existing claim; and if the person who has such a claim, nevertheless agrees to give credit, either with or without a bill of exchange for the amount, he waives his lien and can never again resort to it. Moreover, there may be a custom to give such credit, as in the case of the Thames shipwrights, so that in the absence of express contract to the contrary, no lien arises. The person may even waive his lien by omitting all mention of it at the same time that he asserts an inconsistent claim to the goods, in presence of the sheriff; and in many other ways, a waiver of this right may take place.

With regard to real property, there is this remarkable difference, that notwithstanding the contract of sale, and the execution of the conveyance by the vendor, he retains in equity what is called the vendor's lien on the estate for the purchase money, or any part thereof that still remains unpaid. And, on the other hand, if a good title to the estate sold is not made by the vendor, the purchaser has in equity a lien on the estate for the money paid by him as deposit or part of the price.

Lien, which is not disturbed by the party, is not affected by the statute of limitations. For the lapse of time, by force of the statute, merely bars the remedy by action; but this natural remedy which the creditor retains in his own hand remains intact, and the debt continuing, there is no reason in the lapse of time why he should not continue to retain the security.

LIEN, MARITIME, differs from the foregoing in two particulars. Its existence is altogether irrespective and independent of possession of the chattel which is the subject of it. Its enforcement is not possible otherwise than by legal process. As may be supposed from the name, it applies to ships, freight, and cargo, and is a charge created sometimes by implication of the law maritime, sometimes by the express contract of the parties themselves.

The occasion of its existence is very various. Seamen have always had a lien on the vessel for their wages, without express stipulation to that effect in the shipping articles. Masters, after being long excluded from this advantage by the common law of England, have been placed on the same footing in this respect with the common sailor by the recent statute, the 17 & 18 Vict. c. 104. The collision of one vessel with another becomes immediately the occasion of lien on the offending ship for the injury sustained by the other. In like manner, salvage, towage, and pilotage, severally originate by intendment of the law a lien on the benefitted vessel for the value of the labour bestowed on it.

All these are instances of maritime lien by implication of the law maritime. There is another for which in view of the law of most foreign nations any express contract is rendered unnecessary by a similar implication of the law maritime of those several countries; but in the view of our maritime law, consequent on the restraint and repression exerted on it by the municipal law through the common law courts of England, bottomry, as it is called, has no valid existence except when it is created by the written contract of the parties, no matter in what quarter of the world or what country the claim may have accrued in. Bottomry is nothing more than a maritime lien on the hull and tackling of the ship, usually created for money borrowed, or for necessities supplied, or repairs done to the vessel, in order to enable her to complete the voyage.

This kind of lien is indefeasible by any change of ownership not effected by sale and transfer under a decree of a court of competent jurisdiction; in all other cases of transfer the charge travels with the vessel into new hands, and no ignorance of the purchaser on occasion of the sale is a defence to proceedings for its recovery. It necessarily supposes, however, the existence of the vessel. If the ship is lost it perishes with her; and some liens at least, bottomry for instance, are such that they involve no personal claim against the owners, and no debt therefore survives the loss of the vessel. Hence it is that maritime risk is a necessary ingredient of a valid bottomry bond. It is enforceable against the ship only on condition of the vessel surviving the voyage named in the instrument.

Although this charge is indefeasible except by the destruction of the property on which it is laid, yet the maritime law in the equitable spirit requisite to the administration of law in human affairs exacts diligence on the part of the claimant in the enforcement of his rights. The Court of Admiralty is the only tribunal with a jurisdiction capable

of enforcing this claim. In the other courts of this country, suits are between persons who, when property is concerned, assert a *jus ad rem*. The object of admiralty proceedings is a *jus in re*; the subject of the proceedings is the *res* itself—the ship: and the first step in those proceedings is the arrest of the vessel, to place her corporeally in the possession of the court. The adjudication which closes the proceedings is not personal, but of the thing, adjudging it to be discharged of the alleged claim or condemning it to be sold for the behoof of the claimant.

It cannot but happen sometimes that a plurality of such charges in different hands exist upon the same ship. This occasions the necessity for considering the priority of equities, which are not always, or even usually, in the order of the priority of charge. For instance, if a British vessel before departing on her homeward voyage is obliged to have recourse to bottomry, say in India, and afterwards putting in to St. Helena in a disabled state is obliged again to borrow on bottomry, and at a subsequent period of the same voyage is driven into another port in a condition to require repairs for which the master executes a third bottomry bond, the court, when the subject of the liens is not equivalent in value to the sum of the bonds, ranks these claims in the order of their equity, the last effected to be paid first, and the first last, on this presumption, that the later charge preserved the subject of the prior liens, which, although postponed in the order of payment, are really in a preferable condition than if the vessel had been entirely lost. Commerce is also favoured by such a rule. The ship is saved, and the merchandise on board is carried to its destination; whereas both must have perished for want of a lender under any other rule. Cases of a much more complicated character do occur, and the rule is not so plain, nor the consideration requisite to assign them to the proper rule so easy. There is this peculiar to wages, that the lien for them ranks first for payment. On so difficult a question, however, we must refer the reader to some such work as 'Abbott on Shipping,' by Serjeant Shee, for a full consideration of it in application to actual cases.

LIEUTENANT is an officer who discharges the duties of a superior, in his name and during his absence; and who acts immediately in subordination to him when he is present.

Thus, in military affairs, the lieutenant-general and the lieutenant-colonel are respectively the subordinate grades to the general and colonel, though in process of time the lieutenant-colonel has come to be the officer actually in command of a regiment, the colonelcy being a sinecure appointment. The lieutenant of a company is also immediately subordinate to the captain, in whose absence he has the same powers. In the British service the lieutenants of the three regiments of foot-guards have the rank of captain; in the royal regiment of artillery, and the corps of royal engineers, there being no ensigns, the subaltern officers were formerly distinguished as first and second lieutenants, but are now all styled lieutenant, the juniors having the pay of second lieutenant. The rank of second lieutenant is still continued in the royal marines. But in fusileer regiments which formerly had this rank, it has been changed to that of ensign.

In Ward's 'Animadversions of War' (1639), it is said, "A lieutenant is an officer of high credit and reputation, and he ought in all respects to be well indoctrinated and qualified in the arts military, and not inferior in knowledge to any officer of higher authority; for an unskilful captain may better demean himself with an experienced lieutenant than an unskilful lieutenant can fadge with a skilful captain."

A lieutenant in the royal navy takes rank as a captain in the army, and the number appointed to ships of war varies with the rate of the ship. A ship of the first rate has eight lieutenants, besides supernumeraries; those of the second, third, &c., rates, have respectively one less than the number appointed to the preceding rate; so that a sixth-rate vessel has three: sloops and bomb-vessels have only two. The monthly pay of a first-lieutenant of seven years' standing, in ships of the first three rates, and that of lieutenants commanding gun-brigs, schooners, and cutters, is 11s. per day. The monthly pay of other lieutenants, for ships of all rates, is 10s. per day.

LIEUTENANT-GENERAL. [GENERAL.]

LIEUTENANT, LORD and DEPUTY. [LORD LIEUTENANT.]

LIFE, MEAN DURATION OF. This is commonly called the *expectation* of life, which, properly speaking, it is not. Of a thousand lives of equal goodness, any one may expect to live as long as he has an even chance of living, that is, till 500 are extinct. This period has been denominated the *probable* life.

The mean duration of life, or the number of years which, one person with another, are enjoyed by individuals of a given age, is found from the tables of mortality, which give, out of a certain number born, the number who are left at every successive birthday. If the absolute average law of human life were given, and if $\phi x dx$ represented the chance of an individual aged x living precisely x moments of time, then $\int \phi x dx$, taken from $x=0$ to $x=$ the longest possible term of life, would correctly represent the average duration of life in persons aged x years. The tables, however, are so imperfect that it is not worth while to attempt the accurate application of the preceding formula, or to use more than the roughest of the processes which will be described in QUADRATURES, METHOD OF. The theoretical imper-

fection of this process consists in its being necessary to suppose that the individuals who die in any one year die at uniform intervals throughout that year; so that, one with another, they enjoy half of their year of death. The mean duration of life is then constructed as follows: Let a be the number living at the age in question, of whom let $b, c, d, \&c.$, be left at the end of successive years. Then $a-b$ die in the first year, enjoying among them $\frac{1}{2}(a-b)$ years of life, while b (who survive) enjoy the whole year. Consequently the a persons enjoy, in the first year of the calculation, $b + \frac{1}{2}(a-b)$, or $\frac{1}{2}(a+b)$ years; and similarly it may be proved that they enjoy $\frac{1}{2}(b+c)$, $\frac{1}{2}(c+d)$, $\&c.$, in the second, third, $\&c.$, years. If these be put together, the result is $\frac{1}{2}a + b + c + d + \&c.$, which, divided by a , gives for the average quantity of years enjoyed by each individual,

$$\frac{1}{2} + \frac{b+c+d+\&c.}{a};$$

or the rule is, add together the numbers left at every age above that given, divide by the number alive at the given age, and add half a year.

If it be judged advisable to make the preceding result a little more mathematically correct, diminish the preceding result by the $\frac{1}{12}$ a -th part of $a-b$. [MORTALITY, LAW OF; DE MOIVRE'S HYPOTHESIS.]

LIFE ASSURANCE, or INSURANCE. [REVERSIONS.]

LIFE-BOAT. A life-boat is a boat constructed with great strength to resist violent shocks, and at the same time possessing sufficient buoyancy to enable it to float though loaded with men and filled with water. Such boats are maintained at most of the ports of this kingdom, always ready to put to sea when vessels are seen in danger of shipwreck, and provided with means for being conveyed to the shore and launched as rapidly as possible.

As early as the year 1785, a patent was granted to Mr. Lukin for a life-boat with projecting gunwales and hollow cases or double sides under them, as well as air-tight lockers or enclosures under the thwarts: these contrivances increased the buoyancy of the boat, and the air-tight cases under the gunwales, by their weight when raised above the surface of the sea, and their resistance when depressed beneath, greatly prevented rolling. Mr. Lukin's boat was strong and buoyant, but it was liable to be disabled by having the sides staved in. A better was Mr. Greathead's, invented in 1789. This boat had five thwarts, or seats for rowers, doubled-banked, to be manned with ten oars. It was cased and lined with cork, which gave it such buoyancy that it would float and be serviceable though so damaged by hard knocks as to be almost in pieces; and this is an accident which the softness and elasticity of the cork is well calculated to prevent. Greathead's boat, by the year 1804, when the Society of Arts voted the inventor their gold medal and 50 guineas, had saved nearly 300 lives

from vessels wrecked near the mouth of the Tynemouth haven. In the year 1807 Mr. Wilson produced a life-boat, for which he received the gold medal of the Society of Arts, although in fact its principle did not differ much from that of Lukin's.

During the next forty years, numerous other life-boats were introduced or proposed for introduction; but all of them were wanting in some or other of the requisite qualities. In 1850 the Duke of Northumberland, as a means of lessening the terrible loss by shipwreck on the eastern coast, offered a prize for the best model of a life-boat. No fewer than 280 plans and models were sent in, which were all patiently examined by a committee appointed by his Grace for that purpose. About 50 of the models were afterwards sent to the Great Exhibition in 1851. The examiners drew up a list of all the good qualities of a life-boat, and noted down the rank of each of the 280 plans in reference to each quality; and then a summary of these partial results, gave an aggregate result for each boat, which determined the amount of its claim to the place of honour. Tested in this way, the prize was awarded to Mr. Beeching, of Yarmouth, as the constructor of the life-boat which combined the largest number of good qualities. It affords a curious comment on this mode of arriving at a judgment by prizes and competitive examinations, that the examiners did not really adopt any one of the 280 plans, although the prize was awarded to Mr. Beeching. Mr. Peake, the master shipwright at Portsmouth, who was one of the committee, designed a boat which comprised many of the features of the competitive boats, and added others suggested by his experience; and this boat, gradually improved in later years, is the one which now constitutes the recognised English model: it is adopted, to the exclusion of all others, by that highly useful body, the "Life-Boat Institution;" many boats on the same construction have been sent to Russia, Prussia, Spain, Portugal, and the colonies.

We copy from the 'Companion to the British Almanac,' for 1860, a brief description of Peake's life-boat in the latest stage of its development. The boats are of two sizes. One is about 32 feet long, 8 feet wide, 4 feet deep, weighs 40 cwt., costs 156*l.*, and is worked by 10 oars; the other is about 28 feet long, 7 feet wide, 3 feet deep, weighs 25 cwt., costs 126*l.*, and is worked by 6 oars. Although there is only one rudder, the boat is nearly alike at both ends; air-cases and chambers are provided in various parts of the interior; while ingenious arrangements are made for getting rid of any water which may have entered the boat. It is generally allowed that the boat possesses in a high degree these eight qualities—great lateral stability; speed against a heavy sea; facility for launching; ease in taking the shore; immediate self-discharge of any water entering it; facility of self-righting if upset; great strength of construction; and stowage-room for a number of passengers. Some features of the construction may be understood from the annexed cuts. In *fig. 1*, representing a vertical longitudinal section of the boat, *DD* are the end air-cases; 1, 2, 3, 4, 5, are trans-

Fig. 1.—Sheer Plan.

Fig. 3.—Body Plan.

Fig. 4.—Midship Section.

verse divisions; the dotted lines show the position and dimensions of the air-chambers within-board, and the tubes through which any shipped water is got rid of. In *fig. 2*, representing a deck-plan of the boat, *AA*, are the deck; *BB*, the relieving tubes (6 inches in diameter); *CC*, the side air-cases; *DD*, the end air-chambers. In *fig. 3*, which is a midship transverse section, *AA*, are sections of the side air-cases; *BB*, the relieving tubes, bored through solid massive chocks of wood; *CC*, are spaces beneath the deck, filled near the midship portion with solid chocks of light wood; while *D* is a section of a small channel, having a pump in it, by which any leakage-water can be pumped out by one of the crew whilst afloat. In *fig. 4*, the exterior form of transverse sections, at different distances from stem to stern, is shown.

The mode of managing these boats will be best described in connection with the National Life Boat Association—originally called, when

established in 1824, the Royal National Institution for the Preservation of Life from Shipwreck. The objects sought to be attained by this body were—to grant funds for making life-boats, boat-houses, and life-buoys; to assist in training boatmen and coast-guardsmen to aid ships in distress; to interchange the fullest information, with corporate bodies and local committees, concerning life-saving appliances; and to reward by money, medals, and votes of thanks, those who might render aid to ships in distress, or to persons escaping from such ships. During a course of 31 years, from 1824 to 1854 inclusive, this useful society was instrumental in saving the lives of 9222 persons from shipwreck—not that the work was all done by this Institution; but that it took its share in a series of well-planned efforts having this as the result. In 1854 came into operation an Act relating to merchant ships and merchant seamen (17 & 18 Vict. cap. 104: "An Act to amend and

consolidate the Acts relating to Merchant Shipping"); by which the supervision and control of such ships was vested in the Board of Trade. Its provisions, among other important matters, related to life-boats. Another benevolent society, the "Shipwrecked Fishermen's and Mariners' Royal Benevolent Society" transferred some life-boats, eight boat-houses, and five life-boat carriages, to the Life-Boat Institution; the two societies took up more clearly defined lines of action than before; and both gave up certain objects which the new Act enabled the Board of Trade to attain more effectually. Since that year, the Life-Boat Institution has greatly extended the series of life-boat stations. In November, 1859, there were 88 life-boats belonging to the Institution, besides about 70 others belonging to various harbour commissioners, dock trustees, Trinity houses, ballast boards, fisheries' commissioners, local committees, and associated boatmen. The Institution furnishes every possible aid to the crews of the life-boats, to whomsoever belonging. In each case there is a boat-house in which to shelter the boat from the weather; and in many instances a carriage on which to launch it. The crews are resolute and steady men, kept to their work by a well-considered arrangement between them and the Institution.

A useful little manual has been published by the Institution; giving instructions how to manage the life-boats. This manual has recently been translated into French by Admiral Paris, for the use of French boatmen.

Although applicable to ordinary ships' boats rather than to life-boats, we may briefly speak of the apparatus for quickly lowering boats. Many lives have been lost through the imperfect way in which boats are hung from the davits over the ship's sides; insomuch that during wreck or burning, either the boat occupies too long a time in being liberated, or it is capsized during its descent. Mr. Lacon, Mr. Berthon, and many other inventors, have turned their attention in this direction, with a view to devise a remedy. Captain Kynaston's *disengaging hooks* are connected with a somewhat intricate but very ingenious apparatus by which boats can be lowered quickly and safely, by persons in the ship (not in the boat). Messrs. Wood and Rogers' apparatus more recently introduced, is in a similar way worked by the seamen on shipboard. But the most original and effective apparatus is that invented by Mr. Clifford, in which the boat is lowered by one person seated in the boat itself, even although there be the weight of a dozen other persons in the boat. There are ropes, blocks, pulleys, rollers, hooks, and other apparatus so cleverly arranged, that the manager of the boat can first lower it to the water's level, and then disengage it altogether from the ship.

Besides life-boats constructed for the especial purpose, there have been several inventions for converting ordinary ships' boats into life-boats upon a sudden emergency, which may be applied by the crew of a ship in distress. The Rev. Mr. Bremmer proposed that empty casks should be strongly fixed in ships' boats upon a plan described by him, which on trial was found to answer perfectly. The silver medal of the Society of Arts was voted to Mr. Bray for an invention by which airtight boxes should be fixed under the thwarts of ships' boats to render them buoyant; but these could not be applied extemporaneously, like some of Mr. Bremmer's plans.

LIFE-BUOY. Any thing being lighter than water, used as a means of personal safety on account of its buoyancy, may be considered a life-buoy. A variety of substances have been tried in various combinations for the purpose of assisting to save life, but seamen differ as to the qualifications or advantages possessed by certain forms of life-buoy. Many ingenious contrivances have been invented and attached to the taffrail of a ship, from which, in case of sudden accident, such as the falling of a man overboard, a buoyant substance could be instantly detached for the relief of the unfortunate person. Some of these have even the means of igniting a blue light for the guidance of the man in the water, by the mere act of letting go. The life-buoys referred to are generally formed of two small casks connected by a strong beam, having a vertical staff thereto attached. Occasions have happened in which a miserable man has been supposed to have reached the buoy which had been cast adrift for his safety, but which a heavy gale or dark night had deprived the crew of all possible means of recovering. It is, however, a point of conscience among seamen, never to leave a buoy adrift on the ocean if recoverable, for fear of abandoning the unfortunate occupant to the worst of all deaths, namely that of starvation.

Many kinds of life-buoys have been made of India-rubber, and adapted for ready inflation by the wearer within the period of a few seconds. One sort is in the form of a waistcoat. But the buoy which seems to have most successfully won its way among seamen of late years is that represented in the annexed cut.

It is composed of slices of cork, so nicely arranged as to form a buoyant zone of about 32 inches extreme diameter, and 6 inches in width, with a thickness of about 4 inches, and containing about 12 pounds of cork, compactly covered with painted canvas and furnished with looped life-lines, as in the drawing.

Taking the cubic contents of the buoy as '86 of a cube foot, and sea-water at 64 pounds the cubic foot, while the cork in the buoy would weigh 12 pounds, and thus leaving at least 40 pounds as extra buoyancy, one of these life-buoys would support about six ordinary human beings, A man of 10 stone, in sea-water is commonly reckoned to weigh

4 pounds; the more he frantically forces his head out of water, the more buoying power he will of course require; but allowing for weight

of clothes, &c., say, altogether, to the amount of 10 pounds each man, this buoy would support four men with certainty.

It is greatly to be desired that human life afloat should be better protected by the means of safety in case of accident afloat. The prejudice against life-buoys is greatly diminishing in the merchant service; and the extraordinary exertions made by the National Life-boat Institution, and the success of their precautionary measures in providing for those in their employ upon the coast, has tended to show that it is no imputation on the courage of a brave man that he seeks to protect his life.

LIFTING, on Easter Monday and Tuesday. A custom which formerly prevailed among all ranks throughout the kingdom, and may be yet partially practised in some of our distant counties. In Pennant's time it was not uncommon in North Wales. Strange as it may seem, this custom is intended to represent, or rather to commemorate, our Saviour's resurrection. The lifting of King Edward I. in his bed, on the morning of Easter Sunday, by a party of the ladies of the bed-chamber and maids of honour, together with the fee paid to them upon the occasion, occurs upon the accoutments of the comptroller of the household of the eighteenth year of that king, preserved in a record in the Tower of London, communicated by Samuel Lysons to the Society of Antiquaries, in 1805.

LIGAN. [FLOTSAM.]

LIGATURE, in modern music, a binding, indicated by a curved line, If two notes on the same degree are thus joined, only the first is to be struck, but the second is to continue its full time. *Ex.:*

In vocal music all the notes which are set to one syllable are bound together. *Ex.:*

In music in the old character, that is to say consisting of longs and breves, the notes in *ligature* were joined, that is, were written or printed side by side. *Ex.:*

And sometimes the two characters were blended into one. *Ex.:*

But the ancient ligature is now become obsolete, and any further explanation of it is unnecessary.

LIGATURE. [SURGERY.]

LIGHT. The laws which govern the phenomena of light, when propagated through a vacuum or a uniform uncrystallised medium, form, with the exception of the laws of reflection, the only branch of optics with which the ancients had a scientific acquaintance. The discovery of single and double refraction, of chromatic dispersion, polarisation, and of mutual interference as exhibited in the various experiments of diffraction, have formed both to the practical and scientific men of modern times the sources of exploration in the grandest phenomena of the physical world, as well as in those which belong to the most delicate scale.

The first branch of this subject has been called photometry, and is confined to light emanating from whatever sources, but unmodified in its progress through space by any external influences, though strictly speaking photometry relates to the comparison, as to intensity, of two streams of light under all circumstances. [PHOTOMETER.]

In our cognisance of the form of objects by the sense of feeling, the hand or other part of the body is brought into contact with the object of our perception, and by some ancient philosophers it was supposed that in like manner rays of *sight* were emitted from the eye in straight

lines, and by their impulse on distant bodies caused our perception of their form and colour. But on examining the structure of the eye [EYE] we find that to whatever luminous object we direct the optic axis, an image of the object is depicted on the retina in connection with a system of nerves, in the same manner that similar pictures are formed by mechanical contrivances, such as lenses upon screens, &c.; hence it is obvious that vision is caused by light proceeding from the observed object. Now since bodies are perceptible in all positions, it follows that light emanates from luminous bodies in all directions; and as to opaque bodies, the light which falls on the irregularities of their surfaces is in a great measure afterwards scattered in all directions, by which they become visible to any number of observers.

Suppose that a luminous point is enveloped by a spherical surface of a certain radius, but having that point placed at its centre, the surface will be obviously illuminated all over uniformly with a brightness or intensity depending on the magnitude of the radius. We can ascertain the connection between this brightness and the radius, by supposing the light from the same source diffused over another and concentric spherical surface of a greater or less radius; it will evidently be more or less intensely diffused in the exact proportion in which the one surface is less or greater than the other. Now spherical surfaces are proportional to the squares of the radii, therefore the intensity of light proceeding in vacuo from any luminous origin must be in the inverse proportion of the square of the distance from that point. We have employed the term *proceeding* as applicable to light, because that by two independent astronomical phenomena, namely, the aberration of light, and by the retardation of the eclipses of Jupiter's satellites, we are alike taught that light, whether of the sun, planets, satellites, or fixed stars, is not propagated instantaneously throughout space, but travels with a velocity in round numbers of 192,000 miles per second. Within the last few years M. Fizeau has succeeded, by a most ingenious contrivance, not only in rendering sensible the time which light takes to travel the distance of a few miles, but even in measuring its velocity by direct experiment. ('Comptes Rendus,' tom. 29, p. 90.)

A ray of light has its origin at a luminous point, whence it diverges in an infinitely small solid or conoidal angle, and is the geometrical element of the total spherical emanation of that point. These rays proceed in straight lines in vacuo or a uniform medium, for no opaque body can screen the luminous point from view, except when placed in the straight line joining the eye of the observer with the origin of the light, or, which is the same, we cannot see through bent tubes; but the modifications suffered by light at the surfaces of bodies, and in the interior of media, cause generally a deflection, sometimes sudden, at others gradual, in the direction of the ray.

If the intensity of light emanating from a luminous point, that is, the illumination of a unit of spherical surface having a unit radius, be represented by i , and a small plane, of which the area is a , be exposed to the same light at a distance r from the origin, and situated perpendicular to the luminous ray, the quantity of light which it receives will be represented by $\frac{a i}{r^2}$; but if the plane, instead of being perpendicular,

be inclined to the direction of the ray at an angle α , the total illumination of the plane will then only be $\frac{a i}{r^2} \sin \alpha$, for $a \sin \alpha$ is the area of

the plane projected in a direction perpendicular to the ray, and this projection at the same distance would evidently receive the whole of the light which fell on the inclined plane: we shall give a few examples of these formulæ.

Suppose that A, A' represent two lights of the respective intensities i, i' , and that PB, PB' are planes which bisect the angles $AP A', C P A'$, respectively; the angle $B P B'$ is obviously then a right angle, and the plane PB as well as PB' will be equally illuminated at the point P by the two lights, provided $\frac{i}{A P^2} = \frac{i'}{A' P^2}$, that is, provided $\frac{A P}{A' P}$ be the con-

stant $\left(\frac{i}{i'}\right)^{\frac{1}{2}}$; then by Euclid, book vi., $\frac{A B}{A' B}$ is equal to the same constant, by which the point B may be found, and $\frac{A B'}{A' B'}$ being still the

same, B' is similarly known; hence if on BB' as diameter a circle be described, each point, such as P , will have the property that planes directed through it to either extremity of the diameter will be equally illuminated by the two lights; but the different portions of the curve itself do not possess this property, which may be too readily supposed from the inaccurate statement of this question in optical treatises.

Let it now be proposed to find the nature of a curve, every element of which shall receive equal illuminations from two given lights. Let r, r' be the radii vectores to any point drawn from the two poles or

lights, and θ, θ' the angles which r, r' make with the axis or line joining the lights internally; then s representing an arc of the curve, the sines of the angles at which r, r' are inclined to an element of the curve are $r \frac{d\theta}{ds}$ and $-r' \frac{d\theta'}{ds}$; and representing the intensities as before, the

condition of equal illumination gives the equation $\frac{i}{r^2} \cdot r \frac{d\theta}{ds} = -$

$\frac{i'}{r'^2} \cdot r' \frac{d\theta'}{ds}$: whence $\frac{d\theta}{d\theta'} = -\frac{i}{i'} \cdot \frac{r'}{r} = -\frac{i}{i'} \cdot \frac{\sin \theta'}{\sin \theta}$ by trigonometry.

Integrating we find $i \cos \theta + i' \cos \theta' = \text{const.}$ which (together with the common trigonometrical equations) gives the polar equation of the curve sought. We should obtain a negative sign, instead of a positive, if we supposed the curve equally illuminated on opposite sides.

Having now considered the laws of the emanation of light from points, we are next to consider its emanation from luminous surfaces, particularly when the direction of the light is oblique to that of the surface. To this end suppose AB, BC to be two planes of equal luminosity relative to a unit of either, and regarding only that portion of the light which emanates in the directions AD, BD, CD , perpendicular

to AB produce AB to meet CD in the point a , and suppose the extent of BC to be taken such that $Ba = BA$, then BC will seem to the eye (receiving the rays in the directions AD, BD, CD) to be of the same extent as its projection Ba , or as that of BA ; but as its luminous surface is greater, it would appear brighter than BA in the ratio of BC to BA or Ba , if the intensity of the oblique emanation from CB were equal to that of the direct emanation from BA . Now we know by experience that it has only the same brightness as its projection, for if we take a bar of heated iron into a dark room, it appears no brighter when viewed obliquely than direct, the only observable difference being in apparent size, which is that of the projection of the bar on the line of vision: hence it follows that the emanation from a unit of the oblique surface is less than that of the direct, in the ratio of Ba to BC , or, which is the same, as the sine of the angle of emanation BCD is to unity. After emanation it follows the same law as direct light, of diminishing in intensity inversely as the square of the distance. This law has been the subject of much contention, but we may remark that something similar occurs in the action of electro-dynamic currents, which, though they follow the law of the inverse square at different distances in a given direction, yet in different directions the intensity varies in a trigonometrical function of the directions of the currents acting and acted upon, and the line of junction. The law above mentioned we should not be warranted in applying to luminous gases, as, for instance, the flame of a candle, since the light of the different parts freely then permeates the mass.

Let ABC represent a small luminous plane, situated obliquely with respect to a point P and $A'B'C'$, its projection taken perpendicular to PA , and finally abc , a similar plane to the latter taken at a distance $PA = \text{unity}$, the quantity of light emitted by ABC to the point P is the same as if it proceeded from $A'B'C'$, and is therefore represented by $i \cdot \frac{\text{Area } A'B'C'}{PA^2} = i \cdot \frac{\text{Area } abc}{PA^2} = i \cdot \text{Area } (abc)$, where i represents the

intensity of the given luminous plane; hence if we have any luminous surface, we may, by dividing it into very small elements, transfer each element to another situated at a unit of distance from the illuminated point; in other words, we may substitute for this surface that portion of a spherical surface with radius unity which would be cut out by a conical surface having P for vertex and exactly enveloping the luminous surface. The calculation of the illumination of any small plane by a luminous surface of any figure is thus reduced to that arising from a portion of a spherical surface having that plane placed at its centre.

Example. A distant luminous sphere subtends a given angle 2α at the eye of an observer: to find its total illumination of a small plane area A placed at the eye and inclined at a given angle β to the right line joining the eye and the centre of the luminous sphere.

Let $P B P$ represent the small plane; with centre P and radius unity describe a circular arc $C A C$, of which the measure is 2α , and which by rotating round its axis $P A$ generates a spherical surface of equal illuminating power with the given sphere. Let the angle $B P A = \beta$.

Take a radius $P Q$ forming an angle $A P Q = \theta$, and which, by revolving round $P A$, traces the circle $D Q D$. The plane $P B P$ is taken perpendicular to the plane of the diagram. Let ω be the inclination of $P Q$ to

the given plane. The spherical element at Q is $\sin \theta \cdot \delta \theta \delta \phi$, where ϕ is the inclination of the plane APQ to that of the diagram, and its

illuminating power is therefore $i \sin \omega \sin \theta \cdot \delta \theta \delta \phi$, therefore the total illumination is expressed by $\int_{\theta \phi} i \sin \omega \sin \theta$, the limits of ϕ being 0

and 2π (where π is the semicircumference to a unit radius), and of θ being 0 and α . When the intensity is uniform, we get the illumination $I = A \int_{\theta \phi} i \sin \omega \sin \theta$. Draw PE perpendicular to the plane BB ; then

in the spherical triangle QAE we have $QA = \theta$, $\angle QAE = \phi$, $AE = \frac{\pi}{2} - \beta$,

and $QE = \frac{\pi}{2} - \omega$; hence by trigonometry

$$\sin \omega = \sin \beta \cos \theta + \cos \beta \sin \theta \cos \phi.$$

Hence $\int_{\phi} \sin \omega \sin \theta = 2\pi \sin \beta \sin \theta \cos \theta \dots$ and now inte-

grating relative to θ , we have $I = A i \cdot \pi \sin \beta \sin^2 \alpha$, as the illumination required. In this investigation the whole of the light is supposed to fall on the same side of the plane.

If a small hole be formed in the window-shutters of a darkened chamber, the rays of light passing from opposite parts of any luminous object outside cross each other in entering the orifice, since they necessarily proceed in straight lines, and therefore form on the opposite wall of the chamber a perfectly inverted image of the external object, and if the latter be in motion, the image will also move in the contrary direction. If m be the magnitude of the object, and x its distance from the hole, and a the width of the chamber, then the light being supposed to enter directly, the magnitude of the image, by the

known laws of similar figures, will be $m \cdot \frac{a^2}{x^2}$. But the total quantity of light which enters the hole (supposed to be of given size) from the

object varies as $\frac{1}{x^2}$, that is, as the magnitude of the image, a being supposed constant, and therefore the brightness of the image is constant for all distances of the object. The eye is such a chamber, and therefore a luminous object should appear of equal brightness at all distances, but the absorption of light by the atmosphere causes the greater dimness of distant atmospheric objects.

If we suppose the quantity of light absorbed by a transparent medium to be a proportional part of the incident light, then denoting by i the intensity of light which corresponds to a space x traversed (or rather, to include the case of divergence, the ratio of the intensity to what it would have been independently of absorption), we shall

have $\frac{di}{dx} = -k \cdot i$, k being a constant dependent on the particular nature of the medium, and by integration we find $i = I \cdot e^{-kx}$ where I is the initial intensity previously to the light entering the medium, and e the base of Napierian logarithms; therefore the intensity will diminish in a geometrical progression for equal spaces successively traversed.

From these principles we are enabled to calculate the laws which the direct rays of light obey, from their emanation to their incidence. If the body on which the latter takes place be unpolished and opaque, a portion of the light enters into it for a small depth, and is there partially absorbed; the complementary portion is scattered in all directions; the surface therefore becomes itself, to that extent, a source of light, but the composition of the differently coloured rays [DISPERSION] may be widely different from that of the incident light: for instance, if the incident light were an equal mixture of red and blue rays, and if the surface favoured the absorption of the latter more than of the former, the scattered or complementary light, then containing more of red than blue rays, would proportionally tinge with red the apparent colour of the surface. Solar light is a compound of various homogeneous coloured rays; and by their unequal absorption or transmission bodies acquire these apparent colours; but the perception of form arises from the variations of light and shade, and the modifica-

tions of light on the borders, ridges, and angles of the surfaces; and the painter, when he produces a relief on a plane surface, imitates those modifications in the colours which he applies. Hence the perception of form is lost when this incident light is excluded, as in a heated square bar of iron in a dark room, which when turned round its axis seems always to be a flat surface, growing wide and narrow alternately as its edges or faces are turned to the eye; and even when incident light is admitted, a greatness of distance from the eye renders those modifications inappreciable unless under the most favourable circumstances; and thus the heavenly bodies, instead of appearing as round solids, are projected upon a spherical surface, having the eye for the centre. When the body exposed to incident light has even a slight polish, the scattered light will then be most copious in the directions in which the regular reflections take place. Such portions of the surface as are situated, relatively to the eye, properly for regular reflections of the incident light, have therefore a much greater apparent brightness than the parts adjacent, and thus assist in producing the ideas of the position and form of the parts.

When the polish of the surface is such that the irregularly scattered rays bear but a small proportion to the regularly reflected light, we become then principally sensible of the effects of the latter in producing images of all the bodies of which the incident light is reflected to the eye: we are thus led to consider the laws of regular reflection.

Let AB represent a surface of mercury at rest, and therefore perfectly horizontal; ET the axis or line of collimation of a telescope, by which we perceive the image by reflection of the star s , and let the angle ACS of its apparent depression below the horizon be measured. Then, turning the telescope in the vertical plane ZCE until its line of colli-

mation takes a position $T'E$, in which the star itself becomes visible, and measuring its apparent zenith distance $T'EZ'$ or scz , this angle is found invariably to be the complement of the former angle ACS . Now, ZCT being the complement of ACS or $T'CB$, it follows that the angles ZCS , ZCT are equal.

This experiment demonstrates that the reflected ray CT is in the same plane ZCS as the incident ray CS and the normal CZ , and that the angle formed by the reflected ray CT and the perpendicular to the surface—that is, TCZ , or the angle of reflection—is equal to scz , the angle of incidence. Such are the laws which govern the reflection of light.

Let us suppose that light consists of a succession of particles emitted from the luminous body at intervals sufficiently short to produce vision, which hypothesis is generally known as that of emission; then the preceding law would result from the supposition that the luminous molecules, on approaching and entering the reflecting medium, are subject to forces proceeding from this medium, and of which the resultant is normal to the surface. For conceive the velocity of the luminous particle as it enters the medium—or rather, as soon as it comes within the influence of its forces, to be decomposed into one parallel and one normal to it. The force of the medium can exercise no influence on the former, and it is therefore the same at the exit of the ray from the influence of the medium as at its entrance. Again, the effect of the normal force on the square of the normal velocity in a space small enough to consider the force uniform, is the product of twice this force and the small interval of space, and it is therefore the same in increasing this quantity for the returning as in diminishing it for the incident ray; and therefore the normal velocities of the incident and reflected rays are equal, as well as the parallel; from whence it necessarily follows that the angles of incidence and reflection are equal. It admits of easy geometric demonstration that the path of the ray between any fixed points in the incident and reflected parts is a minimum (neglecting the insensible curvilinear part), in reference to any other supposed positions of these rays, when the reflecting surface is plane, or any curved surface which is tangent externally at the point of

incidence to a spheroid having the fixed points for foci, and the length of the ray between them as axis major; for those touching the spheroid internally it is a maximum.

If we suppose that light is propagated by undulations in a rare elastic medium from the luminous point as an origin, the velocity of the waves, after reflection, is the same as before incidence, since the medium is the same; and hence, as in sound, the angle of reflection would still be the same as that of incidence. [ECHO.] Thus both the hypotheses of emission and of undulations satisfactorily account for this fundamental law.

If the reflected ray of light were transformed to an incident, reciprocally the path of the incident would become that of the reflected. The same is true for any number of reflections at different surfaces.

The *deviation* of a ray of light, after it has undergone any alteration in its course by the action of media, is the inclination of the primitive and final directions of the ray taken in the sense in which they are moving. This deviation by one reflection on any surface is the supplement of double the angle of incidence, or is the double of the inclination of either ray to the medium.

A *plane of reflection* contains a successive incident and reflected ray, and is necessarily perpendicular to the corresponding reflecting surface.

When there are successive reflections, the inclination of the plane of the first to that of the last reflection is the *deviation in plane*, the last ray being then in a different plane from the first, the first kind of deviation, or that of direction, is the angle between the first ray produced beyond the incident point (which is the course the ray would have pursued if unreflected), and a parallel to the last ray drawn from the same incident point.

When light is reflected by two parallel planes there will be neither deviation in plane nor in direction; more generally there will be no deviation in plane when the first incident ray is in a plane perpendicular to the intersection of the two reflecting planes.

In the latter case, where both reflections take place in the same plane, let us consider the amount of the deviation in direction.

Let $ABCD$ represent the course of the ray reflected at B and C by the reflecting planes EB, EC . Let Ba be the first ray produced, and Bd the parallel to the final ray; then the angle aBd is the deviation. When the other two rays are at opposite sides of the intermediate ray BC (fig. 1), then the deviation of CD from AB is the difference of the

two deviations at B and C , or twice the angle BCF —twice the angle CBE , that is, $2\angle E$, or double the inclination of the mirrors. But when AB, CD , are at the same side of BC (fig. 2), the total deviation is the sum of the deviations at B and C , or twice the angle ECB + twice the angle ECB , which is the same as $360^\circ - 2\angle E$. This is a re-entrant angle when E is acute, and therefore we may then substitute for it the corresponding natural angle $2\angle E$. Hence the deviation is double the inclination of the mirrors when acute, and double its supplement when obtuse. This property is turned to excellent use in Hadley's sextant. In general, when there are any number of reflections in one plane, the total deviation is the sum of the deviations at each reflection, giving negative signs to those where the rays are turned in a contrary way to the first reflection; this sum is independent of the first angle of incidence when the number of planes is even.

With the exception of this case, the ray will deviate not only in direction but in plane. The following results may easily be proved to be true of the course of a ray reflected any number of times at any number of mirrors which are parallel to the same line:—The inclination of the ray to the above line will be constant throughout its course, and the projections of the rays on a plane perpendicular to the mirrors will obey the law of reflection of rays coinciding with those projections.

When light diverging from any luminous point falls on a plane

reflecting surface, it will after reflection diverge accurately from a point similarly situated at the opposite side of the mirror. Let s be the luminous point, DE the mirror, draw SA perpendicular to the mirror,

and produce it until $AS = AS'$; let SB be an incident ray, join sB , and produce it to c , then it is evident that $\angle SBA = \angle SBA' = \angle CBE$. Now BC , being in the normal plane SAB , and making, with the normal BF , an angle CBF equal to the angle SBF of incidence, must therefore be the reflected ray. The position of s being independent of that of B , the point of incidence, it follows that every other reflected ray bc will diverge from the same point. Thus the reflected light will appear to an eye c as if proceeding from a point s behind the mirror similarly situated with s .

Hence if any body PQ be placed before a mirror DE , the light which emanates from P will appear after reflection to proceed from the similarly situated point p behind the mirror, and thus an image pq exactly similar to the body PQ will be seen by looking at the mirror; the common looking-glass is a familiar example.

If we seek generally the nature of a surface by which light converging to or diverging from one given point may after reflection diverge from or converge to another, it will be simplest to seek first the plane curve possessing the same property, then the surface generated by the revolution of this curve round an axis passing through the two given points will evidently be of the nature required.

Let r, r' be the radii vectores drawn from a point of the curve to the given points, one will correspond to an incident, the other to a reflected ray; and let s be an arc of the curve measured from a fixed point to that of incidence, then $\pm \frac{dr}{ds}$ is the sine of the angle of incidence, using the upper or lower sine according as r increases or

diminishes with s ; hence we must have $\frac{dr}{ds} + \frac{dr'}{ds} = 0$, whence $r \pm r' =$

const. Taking the upper sign we have an ellipse, or with the lower an hyperbola, of which the two fixed points are the foci: hence the prolate spheroid and hyperboloid are the surfaces sought. But if the incident light fall in parallel rays, and is reflected to one point, take the axis of x through this point in the direction of the rays, the sine of

incidence is then $\pm \frac{dx}{ds}$, whence $\frac{dr'}{ds} \pm \frac{dx}{ds} = 0$, $r' \pm x = \text{const.}$, which is the equation to a parabola having the given point for focus; therefore the paraboloid of revolution is the required surface.

But when light diverging from a point falls on a surface, after reflection it generally does not again converge to a point, or diverge from one accurately, nor does even an infinitesimal pencil in general after reflection pass through a focal point, but only through two infinitesimal focal lines, lying in two rectangular planes passing through the pencil. These lines lie respectively on two sheets of a surface, which may be called the caustic surface, which is touched in each sheet by every ray of the system. The consideration of caustic surfaces is, however, ordinarily restricted to the case of a system of rays symmetrical about an axis, in which case one sheet merges in a line along the axis, and the other, to which the term *caustic* is ordinarily restricted [CAUSTIC], becomes a surface of revolution, generated by the revolution of the curve of ultimate intersection of the rays which lie in any plane passing through the axis. The equations and properties of caustics are, however, rather objects of analytical exercise than of any practical use. [OPTICS.]

In the case of reflection, the light is returned to the medium in which it moved previous to incidence; but when a ray of light is incident on a transparent medium of greater density than that of the medium in which it originally moved, a portion of it is reflected, but another portion enters the medium, and then proceeds generally in one straight course in the plane of incidence, but not in the original direction, having a deviation in course, though not in plane, and sometimes, as in certain crystallised media, it splits into two rays, one in the plane of incidence as before, the other in a plane determined by the nature of the crystal, while in other crystallised media it splits

into two rays, of which neither lies in the plane of incidence. The same phenomena take place when light passes from a dense to a rarer medium, except that in this case the whole of the light may under a certain incidence be totally reflected.

This alteration of the path of light passing from one medium to another, which is familiarly observed in the apparently bent form of a straight stick partially immersed in water in an oblique direction, is called refraction. As double refraction is of comparatively rare occurrence among the instances of refraction which ordinarily fall under our notice, we shall first attend to the laws of single refraction.

Let NPC represent a solar beam in vacuo and incident at C on a

transparent medium (as water), to the surface of which DE is normal. When the medium is fluid, place a graduated circle DSE in the plane of incidence with its centre at C ; a portion of the light will be reflected in the direction CL , and another entering the medium will be refracted in the direction CR . If uninfluenced by the medium, its direction would have been CS . The angle RCE is the angle of refraction, PCN or ECS of incidence, and SCR of deviation. The arcs DP , DL , are equal by the law of reflection, and if we compare the arcs DP , ER , their sines will be found in a constant ratio, depending on the nature of the medium, but independent of the angle of incidence. Thus if i be the angle of incidence, and r that of refraction, the two are connected by the simple relation $\sin i = \mu \sin r$. The constant μ peculiar to the medium is called its *index of refraction*. When the medium is solid, we can easily compare the tangents of the angles, and thence their sines. The above law will be found rigorously exact.

This law may be accounted for on the theory of emission. Let v be the velocity of the ray before incidence, which is decomposable into a horizontal velocity, $v \sin i$, and a normal one, $v \cos i$. The former will not be affected by the medium; the square of the latter will be increased at the confines of the medium by a quantity n^2 , which is the sum of the products of twice the force into the element of the normal throughout that inappreciable space in which the forces of the medium do not destroy each other, in consequence of proximity to the surface. Therefore the normal velocity of the refracted ray is $\sqrt{v^2 \cos^2 i + n^2}$ and its actual velocity $\sqrt{v^2 + n^2}$; so that the horizontal velocity in the medium is $\sqrt{v^2 + n^2} \sin r$, which being equated with $v \sin i$, its value before incidence gives $\sin i = \mu \sin r$, where $\mu = \frac{\sqrt{v^2 + n^2}}{v}$.

How are we to account for the reflected ray CL ? Why is not the whole incident light refracted? Even when the incident light is perpendicular to the refracting surface, a portion of the light is reflected; and when the ray has but a very small inclination to the surface, a portion will yet be intruded. Hence we may consider generally that the incident light consists of portions which are differently disposed to be subject to the repulsive and attractive forces of the medium, or, in Newton's language, are in *fits of easy reflexion or transmission*. When the angle of incidence increases, the normal velocity of the ray diminishes, the effect of the repulsive forces is therefore augmented, or the reflexion is more copious.

If r, r' be any portions of the incident and refracted rays measured to fixed points in their directions, and v, v' the corresponding velocities, and we make ACB the axis of x , we have $\sin i = \frac{dr}{dx}$, $\sin r = -\frac{dr'}{dx}$, and since $v \sin i = v' \sin r$, therefore $\frac{d}{dx} (vr + v'r') = 0$; and $vr + v'r' = \text{minimum}$, which result is agreeable to the dynamical principle of least action.

On the undulatory theory each portion of an incident wave, as it arrives at the reflecting and refracting surface, is conceived to be the centre of a disturbance which spreads out in each medium with the velocity of propagation appropriate to that medium. Thus, setting aside the incident waves, the disturbance in the two media is conceived of as the aggregate of the disturbances due to these various elementary or secondary waves, a mode of conception the legitimacy of which rests directly on the general dynamical principle of the superposition of small motions. In this way the laws of reflection and refraction are simply deduced [UNDULATORY THEORY OF LIGHT], and with respect to refraction, it is shown that the ratio of the sine of incidence

to the sine of refraction is that of the velocity of light in the first medium to its velocity in the second. Hence, according to this theory, light must travel more swiftly in vacuo than in a refracting medium in the ratio of μ to 1, while, according to the theory of emission, it must travel more slowly in the inverse ratio. This leads to a crucial experiment for deciding between the two theories, which is decisively against the theory of emission. [UNDULATORY THEORY.]

The fact that the differently coloured rays have different refractive indices has been thought by some to offer a great difficulty to the undulatory theory, inasmuch as the velocity of propagation within refracting media must depend on the periodic time of the disturbance, which is contrary to the laws of elastic fluids. The circumstances are, however, different, as the fluid in this case envelops the material particles of the medium, instead of constituting one uninterrupted mass. Besides, the fact of dispersion has been accounted for on this theory, and even its law (in the case of substances of low dispersive power) deduced, by adopting certain dynamical hypotheses not improbable in themselves.

If μ be the index of refraction when light passes from vacuum to a medium (A), and μ' when it passes from vacuum to a medium (A'), then $\frac{\mu'}{\mu}$ is the index when the ray is transmitted directly from the former to the latter.

For if we look at a star through a medium bounded by parallel planes, as a plate of glass, its position will not be affected, and therefore the emergent light is parallel to the incident; but since the second angle of incidence is equal to the first angle of refraction by the parallelism of the planes, and the second angle of refraction is equal to the first of incidence by the parallelism of the rays, therefore the index of refraction out of a medium into vacuum is the reciprocal of that from vacuum into the medium. Again, if we place in optical contact two plates of different refracting media A, A' , as for example a horizontal plate of glass covered with water, the emergent light is still parallel to the incident. Now the second angle of incidence or first of refraction is given by the

equation $\sin i' = \frac{1}{\mu} \sin i$; and the second angle of refraction or third

of incidence, by the equation $\sin i = \mu' \sin r'$: whence $\sin i' = \frac{\mu'}{\mu} \sin r'$. Hence, generally, if the emergent ray be supposed to become incident, the latter will take the place of the emergent.

This fact shows that the velocity of light which traverses several media is the same as if transmitted directly from vacuum to the last medium, which is consonant to both the theories of light. In the wave theory, the velocity of the waves in a medium is independent of the mode of their propagation, and in that of emission the increment of the square of the velocity generated at one surface of a medium is destroyed by like forces on its emergence at the second, so that the only increment it finally receives is that generated by the surface of the last medium it enters, and which it would receive if it entered this medium directly from vacuum.

The index of refraction is greater than unity from a rarer to a denser medium, and less than unity from a denser to a rarer. Hence in the latter case there is a limit to the angle of incidence, beyond which it is impossible for the ray to emerge into the rarer medium, for

since $\sin r = \frac{1}{\mu} \sin i$, it follows that r is a right angle when $\sin i = \mu$, or the emergent ray is then parallel to the surface; but if $\sin i > \mu$, then $\sin r > 1$, which is impossible. Observation shows that the light is then totally reflected.

Let us now trace the progress of a ray passing through a medium terminated by planes inclined at a given angle α , as in the case of light refracted by a glass prism. Let μ, μ' be the indices of refraction into the medium through its first bounding plane, and out of it through the second, and let i, r be the first angles of incidence and refraction, i', r' the second, and D the total deviation, and suppose the plane of incidence to be perpendicular to both planes, so that there may be no deviation in planes; the following equations fully describe the progress of the ray: $\sin i = \mu \sin r$; $\sin i' = \mu' \sin r'$; $\alpha = r + i'$; $D = r' + i - \alpha$: thus i being given, the first equation determines r , the third r' , the second i' , the fourth D .

When the deviation is a minimum we have $\frac{dD}{di} = -1$, and generally $-\frac{di'}{di} = \frac{dr}{di}$; and by differentiating the other equations we have

$$\cos i = \mu \cos r \cdot \frac{dr}{di}; \cos i' = \mu' \cos r' \cdot \frac{dr'}{di};$$

$$\text{therefore } \cos i \cos i' = \mu \mu' \cos r \cos r'$$

$$\text{by squaring } (1 - \sin^2 i) (1 - \sin^2 i') = \mu^2 \mu'^2 (1 - \sin^2 r) (1 - \sin^2 r');$$

$$\text{or if } m = \frac{1}{\mu'} \text{ then } (m^2 - 1) \cos^2 i = (\mu^2 - 1) \cos^2 r$$

$$\text{and } \left(1 - \frac{1}{m^2}\right) \cos^2 r = \left(1 - \frac{1}{\mu^2}\right) \cos^2 i'.$$

When the ray after the second refraction moves in the same

medium as before the first incidence, we find the minimum deviation when $i = r'$ and $r = i'$; the internal part of the ray is then equally inclined to both planes. We have then $r = \frac{a}{2}$, $i = \frac{D+a}{2}$, $\mu = \frac{\sin \frac{1}{2}(D+a)}{\sin \frac{1}{2}a}$, which affords a simple method of determining the index of refraction of media capable of being formed into prisms.

When light emanating from one point is refracted accurately to another, if r , r' represent the incident and refracted rays, and s an arc of the curve by the revolution of which the refracting surface is generated, $\frac{dr}{ds}$, $\frac{dr'}{ds}$ are the sines of the angles of incidence and re-

fraction (abstracting from their algebraical signs), therefore $\frac{dr}{ds} \pm \mu \frac{dr'}{ds} = 0$ and $r \pm \mu r' = \text{const.}$: this equation belongs generally to a curve of the fourth order, but if r be infinite, or the incident light parallel to the axis, it gives a conic section, and if the arbitrary constant vanishes the equation $r = \mu r'$ represents a circle. If one surface be given, it is easy to find a second by which homogeneous light may be refracted accurately to a given point.

When light is incident on the generality of crystallised bodies, the ray is refracted in two directions, one of which in uniaxal crystals obeys the ordinary law of refraction, but neither in biaxal crystals. On the theory of emission the forces cannot here be simply normal to the faces of the crystals, but have a connection with the directions of the axes of crystallisation, while on that of undulation the inertia of the ether within such bodies, or else its elasticity, is different in different directions, and the form of the wave-surface ceases to be spherical. The further consideration of that subject will be resumed in the article POLARISATION OF LIGHT.

The formation of foci and images by reflection and refraction follows from the simple laws here discussed, for an account of which the reader may refer to OPTICS; the description of the instruments constructed to take advantage of the properties of light being given in LENS; MICROSCOPE; MIRROR; OPTICS, PRACTICAL; TELESCOPE.

The laws of the reflection and refraction of light admit, as we have seen, of being satisfactorily explained according to either of the two theories respecting which the scientific world was once divided. But while the undulatory theory explains the interference of light, and traces into their most minute details the curious and complicated phenomena of diffraction, no satisfactory account has ever been given of these phenomena on the theory of emission. The remarkable phenomena of polarisation again, so difficult to conceive on the theory of emission, fall simply and naturally into their places on the theory of undulations, when once the doctrine of transversal vibrations is admitted. And even to go no farther than the laws of reflection and refraction, which entail the necessity of making opposite suppositions, on the two theories, respecting the velocity of light within refracting media, the crucial experiment of M. Foucault's already alluded to ('Annales de Chimie,' § 3, tom. 41, p. 129) is decisively in favour of the theory of undulations.

It must be confessed that there is one phenomenon, perfectly simple according to the theory of emission, which presents a serious difficulty on the theory of undulations, namely, the astronomical phenomenon of aberration, according to which a star appears displaced from its true position, in a direction towards the point towards which the earth is moving, by a small angle measured by the ratio of the velocity of the earth to the velocity of light, multiplied by the sine of the angle between two lines, drawn, one in the direction of the earth's motion, the other from the earth to the star. The common explanation of this phenomenon involves the tacit assumption that the rectilinear propagation of light is not affected by the motion of the earth. We might have expected beforehand that, just as a ship in moving through the water would disturb in its neighbourhood the course of little ripples with which the surface might be covered, so the earth in moving round the sun would push the ether out of its way, and thus disturb the course of progress of the little tremors of which light consists. To get rid of this difficulty, many adopt Dr. Young's supposition, that the ether allows the earth to pass freely through it as the wind does through a grove of trees. The rectilinear propagation of light, and consequently the phenomenon of aberration, is however explicable without making this rather startling supposition, by supposing the motion of the ether consequent upon the motion of the earth to be of a particular kind. See several articles in the 'Philosophical Magazine,' 3rd series, vols. 27 to 32.

The production of colours by ordinary refraction is considered in the articles DISPERSION and RAINBOW; for that produced by light passing near the edges of bodies, and by interference, the reader may consult DIFFRACTION and INTERFERENCE. For the colours of plates, see UNDULATORY THEORY.

LIGHT, ABSORPTION OF. [ABSORPTION OF LIGHT.]

LIGHT-BALLS, for military purposes, are hollow cases, either spherical or in the form of cylinders, terminated at each extremity by a hemisphere: they are filled with a combustible composition, and being thrown, by night, in a burning state from mortars, or in some cases from the hand, they serve to discover the working-parties or troops of the enemy.

The spherical cases are made of canvas or cartridge-paper, cut into eight equal gores of a proper form and the edges sewn together, a hole being left for the introduction of the composition and the application of a fuze. The oblong cases consist, frequently, of two hollow hemispheres of iron, which are connected with each other by four slender bars of iron attached to their bases, in positions parallel to the axis of the case, and the whole is then covered with canvas: the entire length is about $1\frac{1}{2}$ calibre of the piece of ordnance from which the ball is to be projected,—a mortar of one of the four different kinds, the calibre varying from $4\frac{1}{2}$ inches to 10 inches.

The composition consists of pulverised saltpetre ($6\frac{1}{4}$ lbs.), pulverised rosin ($1\frac{1}{2}$ lbs.), ground sulphur ($2\frac{1}{2}$ lbs.), and linseed oil ($\frac{1}{2}$ lb.). The dry materials, after having been passed through a sieve, are mixed with the oil while the latter is in a boiling state; and sometimes a small quantity of mealed gunpowder is added. The oblong balls are filled by passing the composition through a fuse-hole in one of the hemispheres and are afterwards strengthened by cord wound about them. The fire is communicated to either kind of ball, at the time of being projected, by means of a piece of quick-match in the fuse.

Previously to besieging a fortified place, the works and the ground about them are reconnoitred, usually by night; the first trenches are also traced and formed during the hours of darkness, and therefore the defenders, at the commencement of the siege, prepare some mortars charged with light-balls: these balls being thrown beyond the glacis, enable them to discover the operations of the enemy, and direct a fire of shot against them. The assault of a breach is also frequently made by night; and in this case light-balls are thrown by the defenders into the ditches of the place for the same purpose. These may be made by merely filling grenades with the composition above mentioned, and they may be thrown by hand.

Major-General Sir J. T. Jones states ('Journal of Sieges') that the defenders of the towns which were besieged by the British army in Spain threw light-balls in order to discover the operations of the attack; and that two or three men of the engineers' brigade were kept in readiness to run up and extinguish them as they fell. That officer adds that the men generally succeeded, in a few seconds, in smothering them with filled sand-bags, or by shovelling earth over them. Some casualties are stated to have occurred among the men so employed, but the fire of the enemy being directed against them was thereby diverted from the working-party often employed at only a few yards' distance from the ball. On account of the great utility of such balls for illuminating the ground occupied by the enemy, Sir J. T. Jones recommended that grenades or other missiles should be connected with them by pieces of chain, in order that, through the risk of the explosion, men might be deterred from attempting to extinguish the light.

It may be added here that spherical cases of pasteboard or canvas filled with a composition which while burning emits a great quantity of smoke, are frequently discharged from mortars in order to conceal a movement of troops from the view of the enemy: they are also occasionally thrown from the hand either to suffocate the men employed in the galleries of military mines or to compel them to quit their work: these are called smoke-balls. The composition consists of mealed powder (5 lb.), pulverised saltpetre (1 lb.), pulverised seacoal ($1\frac{1}{2}$ lb.), pitch (2 lb.), and tallow ($\frac{1}{2}$ lb.): the pitch and tallow are melted together, and the dry materials, after being sifted, are mixed with the liquid.

LIGHT, BAROMETRIC. [BAROMETER.]

LIGHT, CHEMICAL ACTION OF. [CHEMICAL AFFINITY; LIGHT, PHOTOGRAPHY.]

LIGHT-EQUATION. In consequence of the time employed by light to traverse the solar system, phenomena are not seen at the exact moment of their happening. The first step in astronomical prediction is the finding the absolute moment of time at which a phenomenon occurs; the next is to apply a correction which gives the time at which it is seen at the place for which the prediction is made. This correction or equation is called the light-equation. This term is however principally applied to the correction which is necessary in the case of eclipses of Jupiter's satellites.

LIGHTHOUSES and DUES. [TRINITY HOUSE.]

LIGHTNING. The general circumstances attendant on a thunder-storm are familiar to most persons. It will however be useful to state some of the most prominent, with a view to their explanation when regarded as electrical phenomena.

At first we see light clouds forming with jagged edges, the relative motions of which are frequently opposite and variable. The atmosphere at the surface of the earth enjoys a stillness and calm, accompanied with some elevation of temperature, as well as considerable barometric and hygrometric changes, which produce on the animal system the sensations of closeness, faintness, and oppression, and appear even to the brute creation indicative of some awful and impending changes. Some of these light clouds appear stationary, as if the forces which produced contrary motions in the others made an equilibrium in these. A low murmuring and continued sound of distant thunder is soon heard, after which the lower region of the air is refreshed with cooler but light breezes of uncertain direction. The calm is resumed, but the thunder-clouds are nearer, apparently larger, and much blacker, and their influence on the nervous system is felt by an

indescribable sensation of uneasiness. Lightning flashes are now perceived at short intervals; their course is sometimes zigzag, when it is called *forked lightning*; the aberrations in its course show that it is near terrestrial objects, and is therefore justly regarded as dangerous. In a few seconds after the discharge, heavy showers of rain or hail descend, and the atmosphere is again cooled. The blackness now becomes universal; the thunder, which before roared continuously and at a sensible interval after the discharge of the lightning, is now heard in a loud and sudden clap almost at the same instant that the lightning is seen descending towards the earth with immense velocity, and resembling a globe of flame.

These phenomena are the most common concomitants of thunderstorms, particularly in summer time. But storms are also produced by rapid changes in the atmospheric currents, for instance when the equinoctial gales usually set in; or, as met with in violent and destructive gales, as in crossing the Atlantic with both a revolving and progressive movement, and becoming mixed with various strata of the air through the regions which they traverse, accompanied in several places by destructive thunderstorms.

The colour of the lightning is generally a variable yellow, but it may also be red, blue, or violet, depending much on the density and composition of the strata of air through which the discharge takes place.

In 1752, Franklin in America, and Dalibard in France, commenced, independently of each other, a series of experiments tending to identify lightning with the discharge of ordinary electricity. [ELECTRICITY, ATMOSPHERIC.] Their identity might well be suspected from the number of analogies known to exist between them. For example, the zigzag path of the electric spark from the prime conductor of an electrical machine to a conductor held within striking distance of it resembles on a small scale the course of forked lightning; both are drawn off by pointed bodies in preference to others, and lightning also prefers, *ceteris paribus*, the best electrical conductors: both can fuse metals and inflame combustibles, destroy sight and animal life, magnetise steel and reverse the poles of a magnet.

Franklin, in June, 1752, perceiving a thunder-cloud approaching, sent up a silk kite attached to a dry hempen cord. The loose threads of the cord stood erect, and upon pointing his finger to the cord, he drew sparks. When in consequence of a little rain the hempen cord became a better conductor, the supply of electricity from the cloud became more copious, and by the smartness of the shock ensuing, the danger of prolonging the experiment was sufficiently indicated.

A similar result had already been obtained in France a month earlier, by Messrs. Dalibard and Delor, acting however in obedience to the instructions sent to Europe by Franklin, in 1749. Atmospheric electricity became a favourite study now that the identity between lightning and ordinary electricity was established. It received a check however in consequence of an accident to Professor Richmann, of St. Petersburg, who having attached a simple species of electrometer to his apparatus for measuring the electric intensity of a thunder-cloud, proceeded, immediately after a loud clap, to read off the indication of his instrument, when a globe of electric fire was discharged through his body, and he fell instantly dead. This was on the 6th August, 1753.

Some of the causes which produce atmospheric electricity are stated under ELECTRICITY, ATMOSPHERIC. It will there be seen that the atmosphere is nearly always in a different electrical condition to the earth, the one being usually charged with positive electricity and the surface of the earth with negative. It was shown also that the electrical intensity increases with the height, that in stormy weather, in rain, hail, or snow, the electricity of the air is much more intense than at other times, and is liable to sudden changes from + to - and from - to +. Now the effect of heat, evaporation, and other causes, is to exalt the electrical condition of the air, while a surface of cloud acts strongly by induction upon another opposed surface of cloud, or upon the opposed surface of the earth beneath, and the two opposed surfaces mutually reinforce each other. The cloud and the earth may thus be regarded as the terminal planes of a highly charged system of dielectric air, the tension of which goes on increasing until any further increase causes it to break down, when the opposite electricities rush together with violence, producing what is called a *disruptive discharge*, or in other words a flash of lightning, accompanied by thunder. During a thunder-storm the air between these two terminal planes may be charged and discharged a number of times until equilibrium is attained, or until the thunder-clouds are borne away by the wind to another locality.

There are various kinds of lightning, presenting different phenomena, and recognised under different names. In the first place there are those narrow well-defined ribbons or lines of light, moving in a zigzag course, of a dazzling white colour, but sometimes of a violet or purple hue; these form, probably, the only kind of lightning that strikes terrestrial objects. It proceeds from a single point, and frequently divides into two or more distinct streams. It is this bifurcation, or trifurcation, that has obtained for it the name of *forked lightning*. When forming a long rippling line of light, sailors call it *chain lightning*. Some admirable illustrations of this, the first kind of lightning, are given under BREATH FIGURES. When the lightning appears to be spread over an extensive surface, and varies in colour, being often red, but

sometimes blue and violet, often confined to the edges of clouds, but when apparently issuing from the interior, the clouds are said to *open*, we have the variety known as *sheet lightning*. Lightning of this kind when unaccompanied by thunder is known as *summer lightning*, and is the reflection in the upper regions of the atmosphere of common lightning, having its origin in a storm, the direct view of which is obstructed by the rotundity of the earth. A third kind of lightning is the *globular*, which appears like a luminous ball or globe of fire; it moves through the air at a comparatively slow rate, while lightnings of the first and second class exist but for a moment. Lightning of this kind sometimes obtains the name of *fire-balls*: it rolls along the surface with a hissing noise, and often terminates in a disruptive discharge. This kind probably arises from a kind of glow or brush discharge in certain points of an excited system of air, preparatory to the more general and rapid union of the electrical forces. A milder form of this variety of lightning is known as *St. Elmo's* or *St. Helmo's* fire to the French and Spaniards, the *fires* of *St. Peter* and *St. Nicholas* to the Italians, while the Portuguese call it *Corpos Santos*, which our English sailors seem to have corrupted into *Comazants*. It appears as tufts of light upon the points of ships' masts, the tips of spears, bayonets; on the alpenstocks of Alpine travellers, on the tips of the fingers when the outspread hand is raised, and on any other pointed bodies, during a peculiarly excited state of the atmosphere, when the particles of air near the bodies in question discharge themselves upon the particles immediately above them, the electrical condition of which is less intense, the effect being a luminous brush of light, accompanied by a slight roaring noise. This *brush discharge* is, in the language of that excellent electrician Sir W. Snow Harris, "an intermitting series of electrical sparks between metal and air, but in such rapid succession as to convey the idea of a continuous stream." In some cases the appearance of the *brush* is changed into that of a *star*, as when proceeding from negative or resinous electricity, when the discharge is *towards* the pointed conductor, and not *from* it as in the case of the brush discharge. A kind of *brush discharge* usually precedes the discharge of a Leyden jar, or of a thunder-cloud upon a ship or building, marking out, as it were, the line of least resistance for the principal discharge. [BREATH FIGURES.]

When lightning strikes the earth the resulting effects are of the most varied character. It is a popular remark that the lightning-stroke is succeeded by a suffocating odour, which has been compared to that of burning sulphur. Scientific chemists have compared it to the odour of phosphorus, or to that of nitrous acid; but it is more than probable that this odour is due to the presence of OZONE, which is probably generated by the action of lightning on the oxygen of the air. The passage of lightning through the air causes a combination of its constituent oxygen and nitrogen in the proportions to form nitric acid (NO_3). It was shown by Cavendish that by passing artificial electrical discharges through a confined portion of air this acid was formed. Liebig has also shown that in seventeen specimens of rain-water, collected during or immediately after thunderstorms, all contained nitric acid in greater or less quantities in combination with lime or with ammonia, while out of sixty specimens collected during ordinary rains, these substances were not found in fifty-eight of them. The formation of ammonia (NH_3) during thunderstorms shows that lightning decomposes a portion of water. The presence of ammoniacal salts in storm rains is of great importance to vegetation, while the nitric acid of the storm is probably one of the sources of the natural nitrates of the earth.

The fusion of metals is one of the commonest effects of lightning. There are instances of an iron chain being traversed by the lightning, the effect of which was to soften the links so that they united by their own weight, and the chain was converted into a rod of iron. Franklin relates the case of a church struck by lightning, which passed along an iron wire 20 feet long, and about the thickness of a knitting-needle, and dissipated it in smoke, leaving a black trail behind. There are cases also of the discharge passing down bell-wires, destroying them entirely, and leaving the oxides resulting from the combustion impressed upon the walls of the room in broad bands. A year or two ago, a house at Paris was struck; the lightning broke several panes of glass in a shop front, and burnt away the gilt letters of the word *Café*. In all cases of this kind the conductor is not of sufficient capacity to transmit the discharge, so that the lightning being delayed in its progress, its astonishing heating power becomes developed, and the result is the fusion and oxidation of the metal. According to Harris, a copper rod three-quarters of an inch in diameter, or an equal quantity of copper under any other form, is sufficient to withstand the heating effect of any discharge of lightning of which the effects have ever been recorded. The wonderful heating effects of lightning are manifested in the formation of *vitrifications* and *lightning tubes*, also known as *fulgurites*. [FULGURITE, in NAT. HIST. DIV.] These are long, irregular, cylindrical bodies of sand, or other siliceous material, fused into a kind of glass or enamel, and appear to have been formed by the lightning striking and penetrating the rock, and fusing the loose materials together. The outer surface of the tube is often rough and uneven, and deeply furrowed, while the interior may be formed of whitish or limpid vitrified matter covered with a smooth glaze, and hard enough to scratch glass.

When lightning strikes solid imperfect conductors, it tears them to pieces, and scatters their fragments to great distances, just as if a

powerful explosive force had been suddenly generated within them. Thus churches unprovided with lightning-conductors have had their steeples and towers destroyed, and heavy stones projected in all directions, to a distance of several hundred yards, while timber and growing trees are torn into shreds, as if from the operation of some powerful internal force, which Arago is disposed to attribute to high-pressure steam, generated by the intense heat of the discharge acting on the sap of the wood. The masts of ships have in like manner been reduced to fragments in a moment. Thus, the log of the *Rodney*, struck by lightning in December, 1838, records the following effects:—The top-gallant and royal-mast, 53 feet long, weighing nearly 8 cwt., entirely disappeared from the ship, with the exception of the end of the royal-mast. The sea was covered with chips and splinters, and "the water alongside looked as if it had received all the refuse of a carpenter's shop." Out of twenty-six immense iron hoops, which were clasped or driven round the mainmast, thirteen were broken asunder, and came rattling down on the deck with a horrid clang; the ravages of the discharge could be traced through 53 feet. The lightning had entered the very heart of the mast, which it charred, and at the point where the lightning escaped was a hole many inches deep. Cases of this kind are very numerous, and are all marked by somewhat similar effects, where the lightning has to encounter a mixed system of good and bad conductors, such as the wood and metal work of a ship, or the stone and metal work of a church-steeple. The lightning will pick out these masses of metal as so many points in the line of least resistance, and in order to get at them, will rend and disperse badly conducting materials; in short, by its behaviour, it so clearly pointed out the remedy to be adopted, namely, that of furnishing a sufficiently capacious line of conduction from the highest points of the ship or building to the earth, that we can only wonder at the blindness of architects and engineers in not adopting the remedy; but most of all are we surprised at the opposition which survived until quite recently at the proposition to supply every ship in her Majesty's Navy with the fixed system of conductors which will be more particularly noticed in the next article.

A very common result of an explosive discharge of lightning, especially in a ship not furnished with proper conductors, is to disturb, weaken, or destroy the magnetism of the compass-needle, or to reverse its poles, to render masses of iron and steel strongly magnetic, even to the steel parts of mathematical instruments and the springs of watches and chronometers. Cases of this kind are constantly occurring, and we need hardly point out the danger to a ship out at sea, with an impaired compass and chronometer. [LOCAL ATTRACTION.]

The action of lightning is every year fatal to man and beast, as well as destructive to property. M. Boudin, in an elaborate work on the subject, has shown that from the year 1835 to 1852, as many as 1308 persons had been killed by lightning in France, which gives an average of six persons every month, and this statement does not include those struck by lightning, but not killed. Out of an annual number of 103, the largest number of deaths is in June, in which there are 22, and in August 19; no deaths from this cause occur during November and the three following months. The number of persons killed every year by lightning is stated on an average to be, 22 for England, 21.83 for the United States, and 9.64 for Sweden. The mortality from lightning among the lower animals appears to be more extensive than among human beings, probably from their being congregated together in larger numbers. Thus we read of 2000 sheep being killed by a single flash of lightning. This occurred in Ethiopia, and is given on the authority of M. D'Abbadie. At Sacco, in the kingdom of Naples, in August, 1858, the lightning killed 120 sheep, out of a flock of 140. Neither the shepherd nor the shepherd-boy was hurt, but a kid which the latter held in his arms was killed. Cases of this kind are not uncommon, in which the shepherd and the huntsman have been spared, while the sheep, the dogs, and the horses have been struck.

Accidents from lightning are more frequent on elevated places than in the plains, and in a village or the open country than in the crowded city. Some of the most disastrous accidents from lightning have proceeded from the explosions of magazines of gunpowder. Large portions of cities have been destroyed from this cause, such as Brescia, in 1769; Malaga, in 1780; Luxembourg, in 1807; Navarin, in 1829; Gaucin, in Spain, in 1843: and many other places down to our own time. The damage to shipping we have already referred to. But we may just glance at a parliamentary paper, belonging to the session of the House of Commons for 1854, consisting of a list of 280 ships of the Royal Navy, damaged by lightning between the years 1790 and 1840. These cases include 106 ships of the line, 70 frigates, 80 sloops and brigs, 2 schooners, 7 cutters, 5 sheer hulks, 5 ships in ordinary, 5 steamers, 2 of which were of iron, so that every variety of vessel has been attacked by lightning. In these cases there were damaged or destroyed 185 lower masts, of which 135 belonged to line-of-battle frigates; not less than 100 were completely ruined; 180 topmasts were ruined or damaged, 150 top-gallant masts destroyed, including of course large quantities of rigging, sails, and other stores. In about one-eighth of these cases the ships were set on fire by the lightning, either in the masts or in the sails, or rigging, and in some cases the ships were severely damaged in the hull. Of course the men on board did not always escape. Nearly 100 seamen were killed, and upwards of 250 dangerously hurt.

Protection from lightning has occupied the attention of persons in

all ages, and has led to many superstitious practices. The ancients believed that lightning never struck deeper into the earth than five feet, so that caverns were favourite places of resort during thunder storms. A grotto containing a reservoir of water has also been a favourite place of retreat. The Romans fancied that seal's skin was a preservative against lightning, and tents were constructed of this material as a retreat for persons during a storm. In the Cévennes, the shepherds to this day wear the skins of snakes in their hats as a preservative against lightning. The ringing of church-bells during a storm is a custom still practised in Roman Catholic countries, under the idea of dispersing the storm: indeed, this is one of the functions assigned to the bell in its baptism. The kindling of large fires in the open air, and the firing of cannon, may also be reckoned among the puny efforts which ignorance sometimes directs against one of the grandest powers of nature. It has been supposed that certain trees are never struck by lightning, and the question is even debated at the present day, as to what trees are most liable to be struck. It is also a favourite opinion that persons in bed have nothing to fear from lightning, and this is to a great extent true, although there are cases of persons having been killed by lightning while in bed. Glass being a non-conductor, it was ignorantly supposed that it would repel lightning, and it was customary to place a thick ball of glass on the projecting points of buildings, ships, and lighthouses. The spire of Christ Church, Doncaster, thus furnished, was destroyed by lightning in November, 1836. Chambers constructed wholly of glass have been made for the use of timid persons during a thunder storm; a useless precaution, since there are cases of glass windows being struck by lightning and the glass reduced to powder.

When lightning strikes persons it particularly attacks any metal which they may be wearing at the time. In July, 1858, a peasant woman near Auxonne in France, returning with her husband from the fields, was struck dead by lightning; her hair was singed, and part of a silver comb melted; the husband escaped with only a slight shock. There are many such cases, where the bracelet, the wire of a bonnet, the watch, &c., have been struck, and even fused without loss of life. Men and animals in a line, as soldiers in a regiment or horses in a stable, are liable to danger at or near the extremities of the line rather than in the centre. There are cases on record of the first and last horse, or the first and last children sitting on a bench, having been killed, while the intermediate individuals escaped. It is difficult to account for cases like these, but probably there are variations in the state of the skin as to moisture or dryness, articles worn about the person, the kind of dress, &c., all very difficult to trace, but which may have some effect in determining the course of the discharge. Franklin advises timid persons, occupying houses which are unprotected by lightning conductors, to avoid the neighbourhood of chimneys during a storm, because the soot is a conductor of electricity. Also to keep as far away as possible from metals, mirrors, and gilded articles. The best place is in the middle of the room, provided there is no lamp hanging from the ceiling. A person is less exposed by avoiding contact with the walls and the floor, and hence the safest of all expedients is to go into a hammock suspended by silken cords in the centre of a large room. If this cannot be done, it is advisable to place between the person and the floor some badly conducting substance, such as a mattress. In short, the position of safety is that in which the body cannot assist as a conductor to the passage of the lightning.

What is called the *return stroke*, is when the electricity of a cloud strikes the earth, and then bounds up again to another cloud. There are many other minute phenomena connected with lightning which are deserving the notice of the student. The subject is treated with great minuteness in Arago's notice 'Sur le Tonnerre,' published in the 'Annuaire du Bureau des Longitudes,' Paris, 1837. Sir W. Snow Harris has also a work 'On the nature of Thunderstorms,' 1843. De la Rive's large work on Electricity also treats on the subject; but perhaps the most accessible book specially devoted to the phenomena of thunderstorms, is by C. Tomlinson, entitled 'The Thunderstorm; an account of the properties of Lightning, and of Atmospheric Electricity in various parts of the World,' published in 1859.

For some notice of the accompaniment of lightning, see THUNDER.

LIGHTNING CONDUCTOR, is a bar of metal, or system of bars of metal, attached in a particular manner to a building or a ship, and extending from below the level of the ground, or from the ship's metallic sheathing, to a point or points several feet above the highest parts of the roof, or of the steeple, if the building have one, or the ship's masts, in order to secure the edifice from the effects of lightning: the upper extremity of the rod or bar should terminate in a point.

From the time when the identity of lightning and electricity was established, a great deal of misapprehension has existed, and continued even to our own day, as to the proper function of a lightning conductor. We have seen it stated by persons calling themselves architects and engineers, as well as by persons holding high official rank, that lightning conductors do more harm than good; that they invite the lightning to the building or ship; that they are a needless expense, and so on: and hence we see new churches built every year without lightning conductors, and every year we read of steeples being knocked down, and churches damaged, or set on fire by lightning; merchant-ships are also sent to sea without conductors, and are sometimes lost or disabled as a consequence of the neglect.

The amount of misapprehension on this subject would form a long history if properly brought together. Soon after the first employment of lightning conductors in Europe, an opinion prevailed that when their extremities were pointed they created a danger which did not exist before, and that they attracted lightnings which would, without the rods, have discharged themselves at a distance; and in order to diminish the risk, it was proposed to crown the summits of the rods with knobs or balls of metal. This notion was entertained by the Abbé Nollet, in France; but in the Royal Society of London the question concerning the relative efficacies of pointed and knobbed conductors was agitated with great vehemence, chiefly through the obstinacy of Mr. Wilson, one of the Fellows, who, in 1778, made himself the head of a party in support of the latter kind of conductors, in opposition to the president. [PRINGLE, JOHN, in BIOG. DIV.] It is remarkable that both George III. of England and Frederick of Prussia placed themselves on the side of the opponents of Franklin; the first king giving the preference to balls over points; and the other, while he consented to have conductors raised on his barracks and powder-magazines, prohibited the erection of them on his palace of Sans Souci. It is now admitted that the prejudice against pointed lightning conductors was entirely without foundation: those conductors have been found not only to protect buildings when struck, but also to diminish the number of shocks which in a given time they have experienced. An experiment which was made by Beccaria, in 1753, might have shown the superiority of pointed conductors over those with balls; for that distinguished electrician set up on the roof of the church of San Giovanni, at Turin, a metallic-rod bent near the top and terminating in a point: the upper part was capable of being turned round by means of a silk line, so that the point could be directed upwards or downwards at pleasure, and the lower part of the rod terminated upon substances which were imperfect conductors of electricity. On directing the point towards the sky when a thunder-cloud passed over the church, electrical sparks issued in abundance from the foot of the rod; but when the point of the rod was reversed so that the bend was upwards, few or none were obtained. The conducting-rod set up by Professor Richmann, at St. Petersburg, may be said to have been the cause of his death (in 1753); but the house would most probably have been struck if there had been no conductor. The immediate cause of the melancholy accident was that the rod led into the apartment, and the unfortunate professor was standing too near its lower extremity. ('Phil. Trans.' vol. xlviii.)

There has also been much discussion concerning the distance to which the protecting influence of the rod extends; the *radius of protection*, as it is called: the French electricians have even gone so far as to define it. According to them, this influence is limited by the circumference of a circle described about the rod with a radius equal to double its height above the top of the building. It will be seen presently that there is no ground for this assumption.

The conditions under which a lightning conductor protects a building not being understood, faults of construction have frequently occurred, and buildings and ships armed with inefficient conductors have more than once been struck. Thus in 1777 the magazine at Purfleet was struck by lightning: the shock took place on an iron cramp which united two stones of the cornice, at the distance of 24 feet from the lightning conductor, measured horizontally; and the upper extremity of the rod was 11 feet above the top of the roof on which it was erected. Again, in 1781, the workhouse at Heckingham in Norfolk, though provided with eight rods, was struck by lightning at a spot which was distant 55 feet measured horizontally from the nearest rod, while the pointed summit of the latter was 22 feet above the level of the part struck; and many other instances might be cited. So, also, the most elevated objects are not always those which are struck by lightning; for in 1829, the sails of a mill at Tothill, in Essex, being at rest, the electric fluid left untouched the arm which was in a vertical position, and fell on a knob of iron at the middle of one of those which was inclined to the horizon in an angle of 45° ; and it has frequently happened that buildings containing in their walls conducting substances have been struck much below their summits by a lateral action of the fluid; bars or plates of metal in the side walls having served to assist its progress to the earth better than the materials on the roof. This happened to the cathedral at Lausanne in 1783.

Now what is the action of a lightning conductor? We have seen in the previous article that the general conditions of a thunder-storm consist in the charging and discharging of a stratum of air situated between a mass of clouds and the earth beneath, which are in opposite electrical states. Now, it will be evident that any artificial elevation on the earth's surface, such as a church on land or a ship at sea, is, with respect to a thunder-storm, a mere point in the lower terminating plane of the great electrical disturbance. The electrical forces cannot be supposed to operate exclusively between such an elevation and a charged cloud. The building or the ship is a mass of matter accidentally placed in a position favourable for the union of the two opposite electricities in a given direction. Electrical discharge always takes place on those bodies which tend to assist its progress. If a church or a ship happen to form part of the line of least resistance, the lightning will pass down that line, and if any damage is done, it is because the structure is made up of good and bad conductors; and the remedy is, to connect all the good conductors into one uniform system

of conduction, so that the lightning, wherever it may happen to strike, may find an easy passage to the earth or the sea.

Hence, then, it is not in general sufficient to erect a rod above the highest point of the building and lead it in a vertical line down to the ground; but it is necessary in an extensive building to connect all the masses of metal, roof-coverings, water-pipes, clamps, &c., into one consistent conducting system; and, more than this, if several points of the building project into the air, each point should have its appropriate lightning-rod. Thus, in a three-masted ship, it is not sufficient to furnish the main-mast with a conductor; for cases are on record of the lightning striking and damaging one of the other masts, which was unprotected, and taking no notice of the protected main-mast. We must, therefore, dismiss from our minds all notions of the radius of protection. A lightning conductor only protects the part to which it is applied, and those parts with which it is in metallic connection; and even this protection will fail unless the rod be of sufficient capacity to carry the heaviest discharge of lightning that ever occurs. The metal must, moreover, be a good conductor even among metals; it must be uninterrupted by any breaks or solutions of continuity, and terminate in the earth where the soil is sufficiently damp to serve as a conductor; for if the ground be very dry it may serve as an insulator, and render the conductor comparatively useless. We must also get rid of the notion that the conductor *attracts* the lightning to the building or the ship. It is a line of least resistance; the lightning passes down it because it can do so more easily by that route than by any other; the conductor is, in fact, passive, and has no more voice in the matter than the rain-shoot in discharging the water that pours down it. The more perfect, then, the conductor, the greater is the protection; and this perfection consists in sufficient capacity, good conducting power, and proper distribution over all the parts of the building. Hence chains, and in general wire ropes, should be avoided, as the form interferes with the conducting power; and there are instances of chains and wire ropes being knocked to pieces by the lightning, and the fragments falling on the deck in red-hot rain, and setting the ship on fire.

The practical mind of Franklin first suggested the idea of providing buildings with a continued line of conduction for transmitting the electricity to the earth. The first lightning conductor in England was erected in 1762 by Dr. Watson, at Payneshill. In Roman Catholic countries there was some difficulty in introducing the "*heretical conductors*," as they were called, until the mob was assured that the gilt points placed at the top to prevent corrosion had been blessed by the pope. The first conductor for ships was in the form of chains, consisting of long links of copper rod about a quarter of an inch in diameter, united by small eyes, turned in each extremity; the chain was tied to a rope, and so attached to the mast-head, whence it proceeded over the side of the ship into the sea. Such a conductor would doubtless contribute somewhat to the preservation of a ship, supposing it were in its place during a thunder-storm, and that the lightning struck the mast to which it was applied. The first condition was almost as difficult as the second, for the wisdom of the Admiralty had led to the packing-up of each conductor in a box, to be taken out and used as occasion required. As might be expected, there are cases where a storm has overtaken and damaged a ship before the conductor could be unpacked; and there are other cases in which the lightning has struck and shivered the fore-mast, to which no conductor was applied, while it avoided the protected main-mast; and there is a third set of cases in which the man sent up with a wire rope or chain conductor has been knocked down by the lightning in the act of applying it.

In the year 1821, Sir W. Snow Harris submitted to the Lords of the Admiralty a plan for protecting ships from the ravages of lightning. It consisted in the application of capacious conductors, so permanently fixed as to render them an integral part of the vessel, and independent of the crew under all circumstances. According to this plan, the masts are converted into lightning conductors by incorporating with them a double set of copper plates, so as to produce an elastic metallic line along their surface, capable of resisting any strain which the spars themselves could support, and connecting these plates with bands of copper leading through the side under the deck-beams, and with the large bolts leading through the keels and keelson, and including by other connections all the principal metallic masses employed in the construction of the hull. The accompanying figure shows the line of conduction on the masts, from the vane-spindle to the stem; and these conductors are connected with the hull and with the sea in the following manner: Under the step is placed a double copper conductor, immediately over the heads of a number of the long bolts which pass through the keelson and the keel, so that when the step of the mast is in its place there is a direct metallic communication between the copper bands on the step and the copper outside the ship. Thus there is an extensive capacious conducting-line from the vane-spindle to the sea; and in order to maintain a more complete connection between the different masts at the junction of the caps, a stout copper hinge or tumbler is employed; it is fixed on the cap, and falls against the conductor without being able to turn far back, so that it has just motion enough to follow the yielding or change of the spar. In the figure, A represents the copper plate fixed on the cap, N M an

angular plate set on the hinge *cd*, while *P* is the conductor on the mast. The transverse conductor, formed of double copper, is secured

to the beams, and connected at each side with the iron knees, *gmhN*, and the bolts *pqr*, passing through the ship and terminating in the

copper sheathing as nearly as possible in the plane of the water-line. The conductors on all the masts, in passing through the ship, are connected with similar transverse bands, led to the side as nearly as possible in the plane of the low water-line. The bands of copper employed for these conductors are 4 feet in length, and vary from $1\frac{1}{2}$ to 5 inches in width, and from $\frac{1}{8}$ th to $\frac{1}{10}$ th of an inch in thickness. Holes are drilled in them 6 inches apart, by which they are secured to the masts by short copper nails. The plates are fitted into shallow grooves in the mast, and are inserted in a double series, placed so as to allow the joints of every two plates to fall upon the centre of another plate immediately above or below it. This plan, which is not in any way protected by a patent, is very minutely described in the "Instructions" for the application of Harris's conductor, printed by order of the Lords Commissioners of the Admiralty. After many years of opposition, the plan was at length introduced into H. M. Navy, and its inventor was rewarded with one of the annual pensions granted to

distinguished men of science, a parliamentary grant of 4000*l.*, and knighthood; a reward by no means excessive, coming as it did in the rear of success, H.M. ships having been struck by lightning in all parts of the world without sustaining any damage; and in some cases the ship has been so severely struck, that she actually "reeled under the force of the discharge" (as the log of one of these ships has it), and, instead of the wreck and devastation which would certainly have followed the absence of conductors, and probably the presence of inefficient ones, no sort of damage occurred.

The application of lightning conductors to buildings is guided by the same principles as to ships. All the metal work of the building should be so connected as to render the whole a good conductor, or to throw it into that passive or non-resistant condition, with respect to the electrical discharge, that, when struck at any given point, its lightning conductors would be so capacious that the electricity would have unlimited space for expansion on the surface of the earth in all directions, to which, as we have seen, the charge is determined. Probably the most extensive system of conductors ever erected are those at the new palace at Westminster, on a plan furnished by Sir W. Snow Harris, and described in the 'Estimates, &c., Civil Service, for the year ending March 31, 1856, ordered by the House of Commons to be printed.'

Harris's conductors for buildings consist either of wide bands of copper, or of copper pipes from 1 to 2 inches in diameter, the metal about $\frac{1}{8}$ th of an inch thick. It is prepared in lengths of about 10 feet, which are united by means of short intermediate pieces furnished with screws. There is a notion among architects that the rod should be insulated, and, accordingly, they attach it to the building by means of rings of glass, forgetting, probably, that when these become wet by the storm they no longer insulate. This is quite unnecessary: the conductor may be supported against the wall by means of coupling-pieces or clamps; the upper extremity should project freely into the air, and should be pointed somewhat like a bayonet, which pointed end may be about 18 inches, $\frac{3}{4}$ inch diameter, and be screwed into a solid plug fixed into the tubing.* In cases where metallic vane-spindles or other metallic points exist, the rod may commence at once from them. The lower extremity of the rod has three divergent branches, which should pass under the surface of the ground, and if possible be connected with a spring of water, a drain, or some other conducting channel. Should the length of the conductor be considerable, its diameter should be increased. In extensive ranges of buildings the most prominent parts should be furnished with conductors, and be connected by horizontal lines running along the ridges of the roofs, &c. In the accompanying figure the strong black lines represent the metallic conductors, of which there is one to each spire *ab*, leading to the metal-

work of the roof and spires, while from the east end or gable *c*, and the transept gables *de*, there are three conductors which unite in the centre of the roof, from which they descend down one of the valleys to the gutters. There is the same arrangement for the smaller gables *fgh*, where the conductors are connected with the rain-water pipes.

LIGHTS, ANCIENT, are known to the law as the foundation of a right for which a man may prescribe over the premises of another to the unobstructed passage of light in the same degree to which it has theretofore been enjoyed by him or those whom he has succeeded in occupation. The light of day is the property of none, and cannot be

* It is curious, that at the time we are writing, a committee appointed by the Academy of Sciences at Paris have just issued their 'Rapport sur les pointes de paratonnerres.' It is printed in the 'Annales de Chimie,' 3^e serie, tome 43.

granted or acquired in property by any. On the other hand, as he who acquires the fee simple of land has a right extending *ab inferis ad superos*, from the earth's centre to the heights of heaven, he may *prima facie* build as high as he will, and dig as low as he chooses at the very verge of his domains. The user of the surface of his land therefore cannot lawfully be in any other without his consent. But if such a user exist, and is of long standing, it is for the interest of society that individuals who have gradually formed their habits and arrangements, and may have incurred expense, and founded contracts with others in accordance with this privilege of user, should not afterwards be capriciously disturbed therein.

It is obvious, that a neighbour's window existing in a wall built to the verge of the adjoining domain, presupposes an access of light to it over the other's land, which he may refuse his consent to, and obstruct by buildings on his own soil. If he do not expressly dissent, and if he do not expressly grant the user for a limited time, and still the user goes on, which is the more common case, the question is whether ever there shall be a time when such user cannot be obstructed. To say that that which began in no right shall by mere length of time become a well established right recognisable in law, is too plainly untenable in point of reasoning to be asserted. Yet the convenience of society required provision to be made for such a result. The judges then, at common law, perceiving this necessity existing not without moral rectitude to justify it, surmounted the difficulty by a fiction; they instructed the jury that from length of uninterrupted user they might presume it to have originated in an unqualified grant of the proprietor and find their verdict in his favour who claimed the continued access of light.

The length of time necessary to justify such a presumption, through uniformity of decision, until it had become a received rule, came to be twenty years. The neighbour's window after so long a time becomes an ancient light. Precision was afterwards given to the practice of the courts under this rule by an Act of Parliament, the 2 & 3 Wm. 4, c. 71, sec. 3 *et seq.*, enacting that after 20 years' uninterrupted enjoyment, the user becomes an indefeasible right, and nothing shall be deemed an interruption to defeat such acquisition of right, unless it has been submitted to or acquiesced in after notice of the act, and of the person authorising it, has reached the person who claims the right.

The right to the free enjoyment of light belongs in the Roman law to the class of Servitudes (easements), among which were the *Servitus altius non tollendi, ne luminibus officiatur, ne prospectui officiatur* ('Dig.' 8, tit. 2, s. 11, 12, 15-17). The general rule is thus expressed by Ulpian: "He who shall attempt to obstruct his neighbour's lights, or to do anything else to damage them, must know that he ought to maintain the form and condition of the ancient edifices. If you and your neighbour cannot agree about the height to which buildings may be raised which you have begun to erect, you will have the privilege of having an arbiter."

The stopping of a prospect is not a nuisance by the law of England, but by the Roman law there was a remedy even in that case, *ne prospectui officiatur*.

LIGHTS, ARTIFICIAL. Most kinds of artificial light, for domestic and manufacturing purposes, are produced by the combustion of coal, solid tallow, liquid oil, or some sort of spirit. One special kind, due to the action of an electric current on charcoal, is described under **ELECTRIC LIGHT**; another, produced by the action of oxyhydrogen gas on lime, is treated under **DRUMMOND LIGHT**; a third, of which the peculiarities are due rather to the apparatus than to the combustible substances, noticed under **LAMP, SAFETY**; while gas-lights are fully treated in the articles **GAS, MANUFACTURE OF**; and **GAS-LIGHTING**.

Candles.—These, in the different varieties of dip tallow, moulded tallow, wax, palm oil, composite, stearine, &c., are described in their nature and production under **CANDLE MANUFACTURE**. We may here simply notice the *Soho* lamp, patented a few years ago, for burning solid tallow or some other kind of fat. The tallow is brought to the form of a long cylinder like a candle without a wick, and is placed in the vertical stem of the lamp; there is a spiral spring beneath it, which presses it up close to a conical cap or cover at the top. A fixed tube passes up through the centre of the cylinder of tallow, from top to bottom; and in this tube is placed a cotton wick dipped in wax, the height of which above the top of the tallow can be regulated by a rack, pinion, and nut. The tallow or fat is made into a hollow cylinder in order to leave room for the central tube containing the wick. When the lamp is to be extinguished, the wick is drawn down below the top of the tube, and again raised before the tallow becomes cold.

One of the projects of this class consists in placing any kind of wax or tallow or fat in a receptacle, having either hot water or hot metal beneath it, so as to keep it in a melted state, fitted to be used in the same manner as oil; but any method of keeping the water or the metal hot would seem likely to be a far greater inconvenience than any supposed good arising from the use of a solid food for the lamp. In another contrivance, however, where the substance employed is either lard or tallow, there is a piece of metal which descends from the flame into the vessel containing the lard; and this metal, becoming heated by the flame, communicates this heat to the lard, and thus keeps it in a melted state. The inconvenience of such arrangements arises from the circumstance that the hot water or a heated piece of metal must be put into the lamp before lighting it, in order to melt

the tallow. When this preliminary step is taken, the tallow is kept in a melted state by various means. One ingenious mode consists in having an air-tube within the wick, to carry air up to the flame, and two projections from this tube penetrating into the flame itself; so that the metal of which the tube is made, becoming heated at the upper end, speedily communicates heat to the contents of the lamp below.

Bude Light.—As something intermediate between gas-light and oil-light, we may notice the Bude light, devised and named by Mr. Goldsworthy Gurney. Originally the light was obtained from an oil-lamp, the flame from which was acted on by a current of oxygen gas: subsequently oil-gas was substituted for the liquid oil; but afterwards the gas which is made for lighting the streets of towns was employed to produce the flame, the brilliancy being increased by a current of atmospheric air ingeniously introduced. The apparatus being suspended from the ceiling, the gas, either as it comes from the street or purified by chemical processes, passes up a number of short tubes into concentric annular receivers, the upper surfaces of which are pierced on the whole of their circumference with small holes. On issuing from the perforations the gas is ignited, and thus there are formed as many cylinders of flame as there are rings; while between and around the several cylinders the atmospheric air rises from below to support the combustion. A hollow frustum of a cone, of glass, open at both extremities and having its larger end downwards, surrounds the tubes above mentioned; its lower part resting on the base of the framework within which they are suspended, and its upper part approaching very near the bottom of the flame, so that the atmospheric air in rising is confined between the upper or smaller end of the cone and the flame. The distances between the cone and the rings, and between the rings themselves, are regulated by experiment so that the quantity of air may suffice to bring the temperature of the gas to exactly the degree necessary for causing a separation of the charcoal from the flame, as nearly as possible at the moment that the latter issues from the perforations. The flame from each interior ring serves to augment the heat of that which is on the exterior of it, by which means an increased intensity of light in each is produced; and almost the whole of the light that emanates from the interior rings passes through the flame on its exterior, into the apartment. A cylindrical glass chimney rests at its lower extremity on the margin of a circular aperture in the middle of a circular disk of iron, from 18 inches to 2 feet in diameter, the under surface of which serves as a reflector: this disk, and with it the chimney, is capable of being raised or lowered, by means of adjusting screws, till it conceals the upper extremities of the flame; and thus the latter presents the appearance of a brilliant zone of white light, which is from 3 inches to 6 inches high, according to the pressure of the gas. An apparatus of this kind supersedes the employment of many separate lamps; and, being placed at a considerable height from the floor, it is possible to apply above the glass chimney a pipe which, while it conveys the impure products of combustion through the ceiling, may serve to ventilate the building or apartment. This is found to be a cheap mode of producing a bright light; but as a similar effect may be produced by other means, the distinctive name of Bude light is not now much employed.

Oil Lamps.—The general character of oil lamps is described under **ARGAND LAMP**. We shall advert here to a few special matters.

One of the difficulties which have lessened the usefulness of common oil-lamps is the tendency of the oil to thicken in cold weather; while another lies in the imperfection of the means for keeping the wick well moistened with oil up to the verge of the flame. Both of these matters have engaged attention within the last few years. The mechanical or *Carcel* lamp, so generally used by the opulent families in Paris, has an apparatus by which the oil is raised through tubes by clockwork, so as continually to overflow at the bottom of the burning wick; thus keeping it thoroughly soaked, while the excess of the oil drops back into the cistern below. Less mechanical and more effective is the *Moderator* lamp, a later invention than the Carcel. The *Meteor* lamp, having some of the properties of the Carcel, is intended to burn rape-oil. The internal arrangements of this lamp are curious and complicated. The lower part of the pedestal consists of a reservoir for containing the oil; and in this reservoir is a kind of piston or plunger, worked up and down by a nut and screw from the outside; the rising of this piston occasions the pressure or tightening of a coiled spring, and this pressure causes the oil to be forced up a central tube towards the flame.

One of the modes adopted for maintaining the oil in a liquid state, is by the use of a lamp constructed by Mr. Parker, in which the oil is used in a hot state. At a small distance around the tube which contains the wick is another tube; and the space between the two tubes, of capacity sufficient to hold a pint, constitutes the reservoir for the oil. The oil is thus so near the flame, that it speedily becomes warm, by which its facility of burning is much increased. A slide valve is opened to allow the oil to descend from the reservoir to the wick. The intensity of the flame is modified by raising or lowering a bell-mouthed glass chimney by means of rackwork mechanism. In a series of experiments on the illuminating powers of different kinds of lamps and candles, Dr. Ure found that the hot-oil lamp, with a given quantity of oil, gave a brighter light than any other form of lamp; or, the light being equal in intensity, the hot-oil lamp was the most economical.

Argand's principle of the mode of admitting air to act on the wick has been the one most generally followed since his time; and many of the subsequent inventions have had relation merely to some modification of this arrangement. The *Solar* lamp, one of the modern kinds, has a provision for sending up air through the interior of the wick, as in the Argand; but the action of the air on the exterior of the wick is made more decided. The wick passes through a hole in the centre of a cap or cone; and the air is admitted so as to act on the flame close to this hole, and in a horizontal direction, while the flame is yet small; so that the exposure of the gaseous products to the air is much more intimate than in the ordinary lamps, and the combustion more complete. Nibb's *oxydite condensing* lamp has a flat wick, with a condensing cap fixed to the upper part of the glass-holder, circular at the base, but tapering upwards to an oblong slot or opening, to allow the flame to emerge from the flat wick. Archer's *pressure* lamp has the oil placed in a flexible bag, with a wick holder, a moveable disk, and a coiled spring. Clark's *pressure* lamp has a strainer or percolator on the lower part of the supply pipe, to prevent impurities from passing into the lamp. Bright's *double-wick* lamp has hollow cylindrical wicks made in a stiffened state ready for use; the wicks are of two different heights, so that one or both parts may be used, according as a weak or a strong light is needed. Among numerous modern arrangements of oil-lamps, some are especially intended for the use of colza or rape-seed oil.

Spirit-Lamps.—In chemical experiments the spirit-lamp has long been a valuable piece of apparatus; but the use of spirit instead of oil, as a food for lamps intended for domestic purposes, is a modern innovation, and has led to much mechanical ingenuity in the construction of the apparatus.

The term spirit is rather a vague one, since there are many kinds of spirit which are inflammable enough to be used for this purpose; but the kind here alluded to is more generally the *spirit of turpentine*, or the liquid distilled from common turpentine by being separated from the resin which is a component ingredient in the last-named substance. When brought to its purest state, this spirit is called by the French chemists *camphine*; and hence the name for some of the modern spirit-lamps. Turpentine being a very abundant produce of the American forests, camphine has long been in use in the United States for lighting shops and public buildings; and it seems to have been from that country that the practice was borrowed and introduced into England. When the import duty on turpentine was lowered some years ago, the price became reduced sufficiently to direct the attention of lamp makers to the practicability of using camphine as a substitute for oil. Many different forms of lamp have resulted from these inquiries; and different processes have also been adopted for freeing the turpentine from a small quantity of oxygen which it contains. Young's *Vesta* lamp is one of those varieties. The principles of its construction are—that, on account of the inflammability of this liquid, provision shall be made for keeping cool the reservoir where it is deposited; that no tube or metal conductor of any description is allowed to pass into or through the liquid from the burning part of the lamp; that a non-conductor of heat is placed between the burner and the liquid; that the cotton wick hangs down from the burner into the spirit, so as to supply spirit to the flame by capillary attraction, without the intervention of any metallic or conducting substance; and that the admission of air to the interior of the wick is managed without the necessity of passing an air-tube through the liquid. All these features and a few others are rendered necessary in the camphine or spirit lamps, on account of the extreme inflammability of the liquid; an inflammability such that the arrangements for an oil-lamp would not be available for a camphine-lamp without much danger. Whether the camphine-lamps receive the name of *Vesta*, or *Gem*, or *Victoria*, or *Paragon*, or *Imperial*, or any other of the many which have been applied to them, they all present in common a reservoir, generally of glass, placed between the supporting pillar and the burner; the spirit is contained in this reservoir, and a cotton wick dips down into it. The chief points in which the several varieties of the lamp differ are in the arrangements for admitting air to the flame.

The increased demand for camphine has raised the price; and it becomes a variable commercial question whether camphine or oil be the most profitable. In a scientific sense, spirit has a great advantage over oil. All lamp-oils contain some oxygen, which neutralises a part of the hydrogen and carbon, and also some oxide or other substance which damps the brilliancy of the flame; whereas rectified camphine, being composed almost wholly of hydrogen and carbon, contains nothing but what is susceptible of combustion. Whether the lamp be so constructed as to admit of this perfect combustion, and also so as to avoid danger, are questions for the consideration of the manufacturer; but in a chemical point of view, camphine seems better fitted for combustion than oil.

It is not alone from turpentine that the spirit may be procured; for tar and naphtha also, if subjected to careful distillation and rectification, will yield a spirit or camphine differing but little from that yielded by turpentine. Mansfield's *Benzole* lamp is founded on an ingenious mode of combining air with spirit vapour. Benzole is a compound of hydrogen and carbon, procured from coal-tar. The mode of employment adopted by Mr. Mansfield consists of sending a

stream of atmospheric air, or of common gas, through a reservoir charged with benzole; the benzole vaporises rapidly, and in so doing combines with the air or gas. The reason for this arrangement is, that benzole and similar hydro-carbons contain too much carbon if burned in the ordinary way in lamps; and that an extra dose of hydrogen is required to ensure perfect combustion. Holliday's *Naphtha* lamp is another apparatus for using a cheap hydro-carbon very rich in the last-named element; the naphthalic vapour, as it issues from the jet, is made to mix rapidly with atmospheric air before combustion. Many analogous arrangements have been planned by Donovan, Lowe, Beale, and others, and have been made more or less applicable to alcohol, oil of turpentine, and wood spirit, as well as to benzole and naphtha. Mechanically considered, Holliday's arrangement is ingenious. The admission of air to mix with the hot vapour is regulated by making the burner revolve on the top of the wick tube; there are perforations in both; when the holes are coincident, the current is at its maximum; but it gradually diminishes as the burner is turned round. We may mention also *paraffine* and *petroleum* among the liquids now used as food for lamps; paraffine being deemed in many respects superior to camphine.

Of the late M. Soyer's *spirit* lamp, intended to give heat rather than light, a brief notice will be found under COOKING APPARATUS.

A few words may be added concerning two important matters connected with lamps; namely, the comparative illuminating powers of different kinds, and the means of carrying off the products of combustion.

Pectet, Dr. Ure, and Dr. Fyfe have all instituted experiments bearing on the former of these two questions. Pectet experimented on candles only. He determined what would be the value of different kinds of candle, sufficient to produce a given intensity of light, as determined by Carcel's lamp as a standard. They rank in the following order, the first being the cheapest:—tallow candles, six to the pound; ditto, of eight to the pound; pressed tallow; stearine; spermaceti; wax. This relation was as to price only. The relative weights of material consumed followed a different order of arrangement, the spermaceti being the least, and the pressed tallow the greatest. In Dr. Ure's list the relative quantities of light for a given price, or the relative cheapness of a given quantity of light, among several kinds of lamps and candles, are placed in the following order:—Hot-oil lamp, with southern whale-oil; Carcel lamp, with sperm-oil; hot-oil lamp, with sperm oil; hot-oil lamp, with common olive-oil; hot-oil lamp, with cocoanut-oil; French lamp, with sperm-oil; mould tallow candles; Palmer's spread-wick candles; stearic acid candles; cocoanut stearine; spermaceti candles; wax candles: the first being, in point of economy, the cheapest, and the last the dearest. Dr. Fyfe's experiments were of a more extensive character, embracing a larger number of sources of illumination. Assuming a given intensity of gas-light as a standard, he experimented on ten varieties of candles, and found their relative cheapness, in producing the given degree of light, to rank as follows:—tallow with single wick, cocoa, composite, palm, tallow with double wicks, wax, diaphane, margarine, spermaceti, and composition. In another table, comparing gas, oil, and candles together, he assumed an Argand gas-flame as a standard of intensity and price, and gives the following arrangement in respect to the ratios of relative cheapness, the intensity of light being uniform:—

Argand gas-flame	1.00
Solar lamp	2.00
Naphtha	2.00
Solar oil in Argand lamp	3.98
Whale-oil	5.00
Sperm-oil	8.00
Tallow-candle (two wicks)	12.70
Cocoa candle	13.10
Tallow candle (one wick)	13.50
Composite	14.50
Palm	18.90
Wax	25.90
Diaphane	27.10
Margarine	28.40
Spermaceti	29.20
Composition	29.20

According to this table, composition candles are nearly thirty times as costly as gas for an equal intensity of light.

Dr. Faraday has introduced an important arrangement for carrying off the products of combustion in gas and oil lamps. This arose out of a complaint, on the part of the members of the Athenæum Club, that the air of their library was vitiated and the binding of the books injured by the lamps then used. Dr. Faraday investigated the subject, and shortly afterwards communicated to the Institute of Civil Engineers the mode which he proposed to adopt for remedying the evil. In a paper communicated to this body he adduced striking proof of the magnitude of the product resulting from combustion. "A pint of oil, when burned, produces a pint and a quarter of water, and a pound of gas more than two and a half pounds of water; the increase of weight being due to the absorption of oxygen from the atmosphere, one part of hydrogen taking eight parts (by weight) of oxygen to form water. A London Argand gas-lamp, in a closed shop-window, will produce in four hours two pints and a half of water; a pound of oil

also produces nearly three pounds of carbonic acid, and a pound of gas two and a half pounds of carbonic acid. For every cubic foot of gas burned, rather more than a cubic foot of carbonic acid is produced." As the water produced deadens the effect of the flame, and as the carbonic acid is very deleterious to the lungs, Dr. Faraday contrived a mode of carrying both off without allowing them to mix with the air of the room. Air is admitted to feed the flame, nearly in the usual way; but when the products of combustion have arrived at the top of the glass chimney, their progress is arrested by a covering of talc, and they are compelled to pass down between the chimney and another larger glass chimney concentric with it. The open space between the two chimneys communicates with a pipe which is conducted in any convenient way into the open air; the carbonic acid, aqueous vapour, smoke, and other emanations from the flame have no means of escape except through this tube, and they are thus wholly cut off from contact with the air of the room. The mode of carrying out the arrangement may be varied in its details; but the general result is said to be that the light is brighter, the space around the lamp cooler, and the air of the room less vitiated than when common open burners are used.

Many other ingenious arrangements have since been adopted by different inventors; either to lessen the production of smoke, or to carry off the products of combustion without allowing them to mix with the air of the room.

LIGHTS AT SEA. So much attention has been already given to this subject under the heading **COLLISIONS AT SEA** in this work, that little remains to be noticed here. The suggestions therein made have been well received by officers of the navy and merchant services, and the question is by no means dormant with the authorities; a perfect system of lighting our coasts seems to be not distant.

LIGHTS, FLOATING. [TRINITY HOUSE.]

LIGHTS, NORTHERN. [POLAR LIGHTS.]

LIGNIN. From the Latin *lignum*, wood. The structure of wood is determined by the superposition of a number of little cells or vessels, more varied in shape but somewhat resembling those of the honeycomb. The material composing this structure is cellulose [CELLS; TISSUES, VEGETABLE, in NAT. HIST. DIV.], but the chief substance which fills up the cell, which incrusts and even penetrates the walls, and which gives firmness and hardness to the whole, is *lignin*. The harder and tougher a piece of wood, the more lignin does it contain.

The purification of lignin, so as to obtain it in a state sufficiently free from other matter to admit of a determination of its composition being made, is exceedingly difficult. Like cellulose it is insoluble in water, alcohol, ether, or dilute acids, and may therefore be freed from many other matters by successively treating it with these agents. Its chief characteristic is, however, a greater solubility in alkaline liquids than is possessed by cellulose.

Lignin contains a greater per centage of hydrogen than is necessary to form water with its oxygen, whereas cellulose contains these two elements in exactly the required proportions, cellulose being represented by the formula $C_{24}H_{20}O_{20}$, whilst lignin has been described as $C_{35}H_{24}O_{20}$. Submitted to destructive distillation lignin yields acetic acid, hence the source of that acid, when wood is strongly heated in iron cylinders, as described in treating of *pyroligneous acid* [ACETIC ACID]. That it is the lignin which chiefly furnishes the acid is proved by the fact that the hardest varieties of wood—those containing most incrusting matter, or lignin—yield the largest amount of acid, when equal weights of the wood are operated upon.

Lignin is slowly acted upon by chlorine, and is dissolved by an aqueous solution of that gas. Sulphuric acid abstracts water from it, and sets free carbon. Iodine does not colour it. It is tasteless and odourless, and is insoluble in water and alcohol.

Lignin is identical with the substance noticed by Payen as *Matière incrustante*.

In its isolated condition lignin has no practical value, but the application of it as *lignous fibre* in the manufacture of linen, cotton, hemp, &c., &c., is obviously of the highest importance.

See also **LIGNIN**, in NAT. HIST. DIV.

LIGNONE, a volatile liquid obtained from crude wood spirit. It is probably a mixture of several substances, as analyses of this body made by different chemists exhibit great discrepancies.

LIGUSTRIN, a bitter solid substance, of unknown composition, found in the *Ligustrum vulgare*.

LILACIN (*Syringin*), a crystalline substance found in the buds and bark of the common lilac. It possesses a nauseous bitter-sweet taste, is soluble in 8 to 10 parts of water, or the same amount of alcohol, but insoluble in ether. Dissolved in concentrated sulphuric acid, the solution first assumes a greenish-yellow tint, passing gradually to a violet-blue, which becomes amethyst-red when diluted with water. Lilacin does not contain nitrogen, but its exact composition is unknown.

LIMB. (Astronomy.) The edge of a planet is called its limb; also the edge of any circle which forms part of an astronomical instrument.

LIME. In building operations *lime*, the dehydrised oxide of calcium, in its various modifications is used for the purpose of forming the material by means of which the small materials used in masonry or brickwork, are bound or cemented together; and the precise word *lime* is used in contradistinction to *plaster* (or the sulphates of lime),

or of *cement* (or the highly silicated carbonates of lime and alumina), to designate the materials obtained from the calcination of carbonates of lime of comparatively pure and simple composition. The various descriptions of limes, technically considered, are those which are known by the names of the rich, the poor, the moderately hydraulic, the hydraulic, and the eminently hydraulic limes; and the application of these names depends exclusively upon the manner in which the respective limes pass through the stages of slaking, or of setting. Very little attention is paid in practical building operations to the mechanical structure of the stones from which the various limes are obtained, and the qualities of the caustic limes themselves constitute the only recognised elements of the classification.

The materials obtained from the calcination of limestones containing less than 6 per cent. of the silicate of lime, and otherwise composed of the pure carbonate, are those called the *rich limes*, on account of the remarkable increase of volume they assume when water is added to them (or when they are *slaked*), for the purpose of being reduced to the state of the plastic material, to be subsequently mixed with sand, for the formation of mortar. They increase, in fact, as much as $3\frac{1}{2}$ or $4\frac{1}{4}$ of their original volume when measured in the lump, and about $\frac{2}{3}$ of their original weight; they absorb in so doing about $1\frac{1}{2}$ times their bulk of water. Naturally contractors prefer limes of this description; for, to use one of their own phrases, "they carry more sand;" but such pure rich limes never *set* (or harden by crystallisation), when in large bodies, or large masses of work, and they are very soluble in frequently renewed water. It follows, therefore, that pure rich limes should never be used for external walling, or for works likely to be exposed to the action of running or of tidal water. In sea water another source of danger arises from the tendency of the lime to pass into the state of the sulphate of that base. Some curious illustrations of the length of time during which large bodies of slaked rich lime will remain in a plastic state are to be found recorded in Vicat's '*Recherches sur les Chaux*.'

When the limestones operated upon contain from 1 to 30 per cent. of impurities, such as the oxides of iron, manganese, magnesia, and sand in the form of insoluble silica, they yield limes which do not increase in bulk when slaked (in any notable manner); and are therefore known as the *poor limes*. The hydraulic limes, to be noticed hereafter, are also poor, in so far as their expansion is concerned; but they differ from the class usually known by that name in this respect, namely, that the poor limes, containing impurities such as are above-named, do not set under water within any reasonable time, if at all; whereas, the hydraulic limes possess that faculty in variable degrees.

The *hydraulic limes* are those which are obtained from the calcination of limestones containing proportions of the silicate of alumina, in combination with the pure oxide of calcium, varying within the limits of from 6 to 30 per cent. of the silicate of alumina in the whole mass; and it appears that it is upon the greater or less rapidity of formation, and of the stability of the hydrated silicate of lime and alumina thus formed by the addition of water to the caustic lime, that this class of materials owes the power of setting under water, and of resisting the solvent action of the latter, from which circumstance its name is derived. When the proportion of the silicate of alumina ranges between the limits of from 6 to 8 or 12 per cent., the lime becomes simply *moderately hydraulic*; when the proportion ranges between 12 and 20 per cent., the lime is *hydraulic*; and when it ranges between 20 and 30 per cent., the lime becomes *eminently hydraulic*; and at last closely approaches the character of the cements. According also to the proportion of the silicate of alumina present in the limestone is the lime obtained from it more or less rich, for the moderately hydraulic limes swell nearly as much as the rich limes in slaking, and with nearly equal rapidity and evolution of heat; whereas the hydraulic limes only increase from $1\frac{1}{2}$ to $2\frac{1}{2}$ of their original volume, they slake slowly, and give out comparatively little heat. In contradistinction to the rich limes, however, they set rapidly in the open air, and permanently under water; for which reasons they alone should be used for exposed or submerged walls. Artificial hydraulic limes are made by the addition of clay, containing soluble silicate of alumina, to the pure carbonate of lime, and by calcining those materials together; or it is made by the addition of pounded and rather under-burnt brick or tile-dust to the mortar of rich limes. The artificial hydraulic limes obtained by the simultaneous calcination of the lime and clay are, it may be observed, much more fitted to resist the solvent action of running waters, than those in which no pyrogenous combination takes place between those elements.

The common chalk lime of the neighbourhood of London may be considered to represent the type of the *rich limes*; some of the impure oolitic stones yield the decidedly *poor limes*; and the blue lias lime may be taken to represent the type of the *hydraulic limes*; the so-called *gray stone lime* of London is simply a moderately hydraulic lime; whilst strictly speaking, the *Portland cement* ought to be considered an *eminently hydraulic artificial lime* [PORTLAND CEMENT]. The gray stone lime is obtained from the basement beds of the chalk; and the *blue lias lime* from the formation of that name. The Romans seem to have used pounded brick dust for the purpose of making artificial hydraulic limes, whenever they could not obtain puzzuolanos, or similar volcanic silicates of alumina; and the modern engineers

have largely employed the latter class of materials, such as the Italian puzzuolanos, or the trass of Westphalia, in their marine works. Of late years, however, the use of the Roman and of the Portland cements has almost entirely superseded that of the mechanical mixtures of lime and the silicate of alumina.

The proportions of sand it may be desirable to mix with a lime for the purpose of making mortars, must vary with the richness of the limes; and it may briefly be said, that it ought to be equal to the amount of expansion of the lime itself in slaking; that is to say, that a lime expanding to 3 or 4 times its original volume may be mixed with three or four times its said volume of sand, and so on. In practice, these proportions of sand may often be exceeded without inconvenience; and it would appear that the chemical nature of the sand has a marked influence upon the character of the resulting mortar; for in proportion as the sand participates of the character of the soluble silicate of alumina, or in proportion, in fact, as it contributes to the formation of a double silicate of lime and alumina, will the compound between it and the lime acquire the property of hardening under water.

It may be added, that when the rich, or the poor limes, are immersed in water, in vessels open at the top, as is done in trials upon the quality of this class of materials, they never set. The hydraulic limes set after 6 or 8 days' immersion, and at the end of about 6 months they become as hard as the softer kinds of chalk; and the eminently hydraulic limes set within 3 or 4 days after their immersion, becoming within 6 months as hard as ordinary limestones. The pure lime itself is soluble, to the very last grain, in water, in proportions varying with the temperature of the latter. Dr. Dalton considered that at moderate temperatures (about 60°), water could take up $\frac{1}{77\frac{1}{2}}$ of its own weight of lime; and at 212° Fahr., it is able to take up about $\frac{1}{1270}$ of that weight. The colouring material used in building operations under the name of lime-white, is merely water containing an excess of lime, to which a little size should be added, in order to counteract the tendency of the lime to detach itself from the surfaces to which it has been applied when the water has evaporated. The rich lime is used in some trade operations, as in tanning; and also to a great extent as a disinfectant in the form of lime-white upon walls, and as a soluble hydrate in the case of waters containing impurities in suspension. In farming operations it is also largely employed, as a dressing or even as a manure; and latterly, the lime-light may be considered to indicate a further remarkable application of this important material. This light is obtained by igniting the united jets of oxygen and hydrogen gas upon a piece of caustic lime, which thus becomes heated to a most intensely luminous degree. The practical applications of lime in building operations will be further referred to under MORTAR; PLASTERING; SLAKING.

LIME, Medical Properties of.—Though lime exists in almost all plants, yet it is more particularly the characteristic element of animal structures, into which it is introduced with the food, as well as often by the water drunk, especially when hard. It is present in small quantity in sea-water (Delabeche). A deficiency of lime in the body causes a softness of the bones to result; while an excess of it occasions preternatural induration of the bones, morbid growths from them, or exostoses, ossifications of the cartilages, of the heart and arteries, as well as depositions of calcareous concretions in various glands and cavities, such as the urinary bladder. [CALCULUS.] The action of lime on the human system varies considerably according to the state in which it is when introduced into or applied to it. Thus quick-lime is violently escharotic, causing inflammation and often decomposition of the part which it touches, and is never employed save when the actual destruction of the part is intended. In a state of great dilution, such as that of lime-water, or when rendered mild by combination with carbonic acid or phosphoric acid, it scarcely produces any immediate or direct action beyond what results from its combining with the acids of the stomach, and, if in considerable quantity, absorbing the mucous and other secretions. It likewise checks the secretions of remote mucous membranes with which it is not brought into contact, such as those of the bronchia. After its absorption into the system, it augments the secretion of the kidneys, and at the same time hinders the excessive formation of uric acid.

Lime-water has an effect beyond what results from its combining with any excess of acid, of a kind to create diarrhoea, for it acts as an astringent and tonic. Hence it removes a tendency to the disease, as well as cures it, when debility is the cause. Its action is often promoted by combination with aromatics, as in the aromatic confection, and occasionally with opium. Carbonate of lime in the form of prepared chalk acts in a similar way, but is accompanied with a disengagement of carbonic acid, which is sometimes beneficial, at other times distressing to the patient. [ANTACIDS; ASTRINGENTS.] Lime-water is often the most effectual means of reconciling the stomach to a milk-diet, and is also of great service in removing the tendency to the generation of worms. [ANTHELMINTICS.] Lime-water with olive oil is a useful application to burns, called carron oil, or *Linimentum calcis* of the Pharmacopœia.

Chloride of lime appears to exercise a specific power over the lymphatic vessels and glands, increasing their activity, so that under its influence various swellings and indurations have first softened and then disappeared. This is the more remarkable as bronchocele, or

enlargement of the thyroid gland, seems to be caused chiefly by drinking water abounding in calcareous salts. Chloride of lime has been strongly recommended in scrofula. It is generally given in the form of solution, but in a dry state, with extract of conium, it is even more useful.

The great tendency of chloride of lime to absorb humidity from the air renders it of much utility in preserving steel and surgical instruments from rust. Hence the presence of a portion of it in chests sent to sea protects the fine edge from erosion. For the use of the chloride (hypochlorite) of lime as a disinfecting agent, see ANTISEPTICS, CHLORINE, and DISINFECTANTS.

Phosphate of lime has been recommended in rickets and other diseases of the bones in which this earth is deficient. Its utility is increased by using at the same time phosphate of iron, or, if that cannot be obtained, the sesquioxide or rust of iron. This salt and many other salts of lime exist in different mineral waters, and some of their effects are due to this impregnation. [MINERAL WATERS.]

Lime-water, if at hand, affords an efficient antidote to poisoning with some of the mineral acids, such as sulphuric or hydrochloric, also oxalic acid. Some of the lime or plaster torn from the walls of the room, diffused through water, will answer this end.

LIME. [CALCIUM; *Oxygen and Calcium.*]

LIME. [MANURE.]

LIME KILNS. The description of ovens in which limestones are subjected to the process of calcination are known by the name of *lime kilns*. These structures are usually built of brickwork lined with fire-bricks, and in shape are either rectangular straight prisms, portions of cylinders, cylinders surmounted by truncated cones, reversed straight-sided cones, or cones produced by the revolution of an ellipsoid. The first three forms are used for what are called *intermittent kilns*, whether of wood or coal; the next two forms are used for what are called *running kilns*, and are those in which coal is burnt; whilst the last of all is most generally used when peat is the fuel employed. In the intermittent kilns the main body of the fuel is applied below the charge, and after it has been consumed the fire is let out and the kiln cooled; in the running kilns the fuel is intermixed with the charge, and the calcined lime, falling to the bottom, is gradually withdrawn as it is burnt, so that the operation is, technically speaking, continuous. Local considerations of the cost of construction, of fuel, and of the nature of the demand, must regulate the choice of the particular description of kiln.

It is calculated that the degree of heat required in a lime kiln is about from 15 to 30 of Wedgewood's pyrometer, and that in intermittent kilns this heat must be maintained for between 3 or 4 days. It is supposed that about 60 cubic feet of oak, 117 feet of fir, about the same quantity of peat, and 9 cubic feet of coal are required to calcine 35 cubic feet of limestone, in intermittent kilns; and that 7 cubic feet of coal are able to calcine that quantity of lime-stone in running kilns. The lime-stones lose, on the average, 45 per cent. of their weight by the evaporation of the water, and the expulsion of the carbonic acid gas; but they hardly diminish in volume more than from 1 to 2 per cent. A great deal of the loss of weight by calcination is permanent; for even after the lime has been hydrated thoroughly, it remains about from 15 to 17 per cent. less in weight than it had previously been, when in the form of the stone.

LIME LIGHT. [DRUMMOND'S LIGHT.]

LIME-TREE: Economical Uses. The wood of the European Lime, which is of a yellowish-white colour, is close-grained, soft, light, smooth, and not liable to be attacked by insects. It is used for the sounding-boards of pianofortes; for many articles of cabinet-work and domestic utensils; for small boxes to contain perfumery and drugs; and for some of the better kinds of children's toys. Curriers, glovers, and shoemakers find lime to be the best wood for their cutting-boards. The colour, grain, softness, and surface texture have given lime-wood a high favour among carvers; many of the fine carvings at Windsor Castle, Chatsworth, and Trinity College Library at Cambridge, are in this wood. Hollar, the wood-engraver, is said to have used lime-tree for his blocks.

The charcoal obtained from the lime ranks next to that from hazel for gunpowder. Baskets and cradles are sometimes made from the twigs. The bark is twisted into rope, twine, and matting, in some countries. The Russian peasants often make the soles of shoes with the outer bark, while the bark of the young shoots is woven into a material for the uppers. They also manage to make baskets and boxes with strips of the inner bark; and employ the outer bark of the older trees as a substitute for tiles and slates for their huts. In various countries the fibres of the inner bark are so prepared as to be used as a substitute for hemp and flax in making fishing-nets, cloth, &c. The matting, so much used by upholsterers and gardeners, comprises, among other kinds, that which is made in Sweden and Russia from lime-bark; the pieces are steeped in water till the layers separate freely; and these layers, when separated into ribands or strips, and dried, are woven or interlaced into matting. The leaves of the lime-tree are used as cattle-food in some parts of Europe. The sap will yield sugar, but not to a profitable extent. A sort of cocoa has been prepared from the fruit. The honey procured by bees from the flowers of the lime-tree is said to excel all others in delicacy. It is an important article of commerce in Lithuania, Galicia, Transylvania.

the Ukraine, Moldavia, and the neighbouring parts of Europe; and the choice liqueur *rosoglio* is mainly prepared from it.

LIMIT: LIMITS, THEORY OF. The word limit implies a fixed magnitude to which another and a variable magnitude may be made as nearly equal as we please, it being impossible however that the variable magnitude can absolutely attain, or be equal to, the fixed magnitude. In this strict sense of the word there are two conditions which must be fulfilled before Δ can be called the limit of P : first, P must never become equal to Δ ; secondly, P must be capable of being made as nearly equal to Δ as we please.

The method of limits is in reality nothing more than one way of evading the use of the word infinite in an absolute sense [INFINITE]: which may be shown as follows. If we take two common algebraical expressions, such as x and x^2 , or x^2 , there can be no objection to saying that when $x=7$, $x^2=49$, because 7 is a definite number, and the operation 7×7 is perfectly intelligible. And we may, if we please, say that when x approaches 7, x^2 approaches 49, so that if x may be made as near as we please to 7, x^2 can be made as near as you please to 49. Or, 7 being the limit of x , 49 is the limit of x^2 . The preceding is superfluous, because it is more simple to say at once that x^2 is 49 when x is 7. But suppose that x , instead of being taken at pleasure, must be determined by means of y ; and let the investigation of the relation between x and y lead to

$$x = 7 + \frac{1}{y} :$$

then, so long as y has any finite value, x must be more than 7; nor can the assertion $x=7$ be made without the implication that y is infinite. In this case then we can only say that x can be made as near as you please to 7, if we may take y as great as we please; in which case x^2 can be made as near as you please to 49. In the language of the article infinite, we say (for abbreviation, as explained in INFINITE) that x is 7 and x^2 is 49, when y is infinite: in the language of the present article, we say that x has the limit 7, and x^2 the limit 49, when y increases without limit. We shall now translate the various illustrations given in the article just cited, from the language of infinities into that of limits.

When z is infinite, Δ is equal to B . If Δ be a fixed magnitude, read—If z increase without limit, Δ is the limit of B : if B be a fixed magnitude, read—If z increase without limit, B is the limit of Δ : if both Δ and B be variables, read—When z increases without limit, Δ and B approach to the same limit.

A finite quantity x , divided by an infinite quantity, is nothing. For this read—When the denominator of a fraction increases without limit, the numerator remaining the same, the fraction diminishes without limit.

Every circle is a regular polygon of an infinite number of sides. For this read—If the number of sides of a regular polygon inscribed in a circle be increased without limit, the polygon approaches without limit to the circle: or, the circle is the limit of all the regular polygons which can be inscribed in it.

When x is infinite, Δ and B are both infinite, but Δ is infinitely greater than B . For this read—When x increases without limit, Δ and B both increase without limit, but the ratio of Δ to B also increases without limit, or the ratio of B to Δ diminishes without limit.

When $x=a$, z is infinite. For this read—When x approaches without limit to a , z increases without limit.

Two infinitely great quantities may have a finite ratio. For this read—When two quantities increase without limit, their ratio does not necessarily increase without limit, but may have a finite limit.

Two infinitely small quantities may have a finite ratio: or—when two quantities diminish without limit, their ratio does not necessarily diminish without limit, but may have a finite limit.

When Δ is infinitely small, B is infinitely great. For this read—When Δ diminishes without limit, B increases without limit.

An infinitely small arc of a curve is equal to its chord. For this read—When the arc of a curve diminishes without limit, the ratio of the arc to the chord, or the fraction $\frac{\text{arc}}{\text{chord}}$, approaches the limit unity.

Of two infinitely small quantities, one may be infinitely smaller than the other. For this read—When two quantities diminish without limit, it is also possible that their ratio may diminish without limit.

Hitherto we have been dealing with considerations which may appear purely verbal, but which are nevertheless connected with the translation of two very different modes of conception each into the other. But were they declared to be merely verbal, they would not be unimportant. It is of great consequence that the fundamental notions of mathematics should be expressed in those terms which have always represented the rude and unrigorous form in which they are expressed in common life: and also, when the form just alluded to has given birth to several different modes of expression, it is necessary to point out the connection of these with each other, and to assimilate their defined meanings. But, so far as demonstration is concerned, we have made no step by using one form of words instead of another, or even by substituting the notion of a limit unattainable for that of the same magnitude attained by the supposition of absolute infinity. The theorem by which rigorous results are obtained is the following: If

two variable magnitudes, Δ and B , be always equal, and if they have limits, namely, P the limit of Δ , and Q of B ; then P and Q must be equal. This proposition may seem almost self-evident; it is not however a perfect axiom, and the method of exhaustions [GEOMETRY] was employed by Archimedes to prove it, or rather, to prove the proposition that if two variable magnitudes be always in a given ratio, their limits are in that ratio. The latter form of the proposition is requisite in Geometry [PROPORTION]; the former is sufficient in Algebra; and the proof is as follows: Supposing Δ and B for instance to be varying lines, always equal, let their limits, if possible, be the unequal lines KL and MN .

Since Δ and B are equal, and since the first can be made as near as we please to KL , and the second to MN , it follows that the latter pair are as nearly equal as we please. But this is not true, since the limits are fixed and invariable magnitudes, differing (if they differ at all) by a fixed and invariable quantity. Consequently the limits cannot be other than equal. The proof of the proposition of Archimedes is given in GEOMETRY.

This proposition, being once understood, is more fruitful in applications than almost any other. We shall give one instance from geometry and one from algebra.

Circles are to one another as the squares on their diameters. For this proposition is evidently true of the regular polygons inscribed in the two circles with the same number of sides; and the polygons may be made as nearly equal as we please to the circles. The limits of the polygons then (or the circles themselves) are in that ratio which the polygons always preserve.

As an instance from algebra, apply the BINOMIAL THEOREM to the development of

$$(1 + nx)^{\frac{1}{n}} = \Delta,$$

which gives, by an easy transformation,

$$1 + x + \frac{1-n}{2} x^2 + \frac{1-n}{2} \frac{1-2n}{3} x^3 + \dots \dots \dots (\Delta),$$

a series which (by the method in CONVERGENT) is always convergent when nx is less than unity. Apply the same method to the development of

$$(1 + nx)^{\frac{y}{n}} = B;$$

which gives in the same manner

$$1 + yx + y \frac{y-n}{2} x^2 + y \frac{y-n}{2} \frac{y-2n}{3} x^3 + \dots \dots \dots (B).$$

Now B is evidently Δ^y ; and if when n diminishes without limit, B and Δ approach the limits P and Q , then B and Δ^y (equal quantities) will approach the limits Q and P^y , which are therefore equal. But the limit of Δ , when n diminishes without limit, is

$$1 + x + \frac{x^2}{2} + \frac{x^3}{2 \cdot 3} + \dots \dots \dots = P.$$

That of B , on the same supposition, is

$$1 + xy + \frac{x^2 y^2}{2} + \frac{x^3 y^3}{2 \cdot 3} + \dots \dots \dots = Q.$$

Hence the second of these series is the y th power of the first; a theorem which the algebraical student will recognise as one of the most important in that science.

The method of limits generally means the Differential Calculus exhibited upon the principles explained in the article DIFFERENTIAL COEFFICIENT. It is admitted, by a large majority of those who are capable of forming a judgment, that the method by which this theory should be established is either the method of limits, or that of Lagrange [FUNCTIONS, THEORY OF], or a mixture of the two. The number of those who contend for the second has very much diminished of late years; and the controversy (if such a thing can be said to exist) lies between the first and third. The reader will find in the eighth number of the Treatise on the subject, published by the Society for the Diffusion of Useful Knowledge, some additional reasons for considering the use of assumed expansions as fallacious. See also SERIES.

It has been customary in elementary mathematical works to endeavour to postpone the theory of limits as late as possible. Such an attempt can never be very successful; a clear understanding of the notion of a limit may easily be, and often is, deferred *sine die*, but the necessity for such an understanding enters with the sixth book of Euclid. We shall even undertake to show [PROPORTION] that the fifth book cannot be properly understood without it.

Wherever we have occasion to speak of a supposition as true, *how ever small a quantity may be*, we are really involving the notion of a

limit. We cannot, for example, even define uniform velocity without it. If s be the number of feet described by a point in the number of seconds t , there is uniform velocity when $s \div t$ is the same for all values of t , however small, begin to reckon t at what part of the motion we may. This is saying that, begin where we may, the limit of $s \div t$ is always the same.

One of the best studies in the theory of limits is the first section of Newton's Principia. In the article PRIME AND ULTIMATE RATIOS we shall present one or two of the leading propositions.

LIMITATIONS, STATUTE OF. [STATUTE OF LIMITATIONS.]

LIMMA ($\lambda\epsilon\iota\mu\mu\alpha$, a remainder), in ancient Greek music, is that which remains of the greater tone when the apotome is taken from it. [APOTOME.] The greater tone, as, for instance, c, d, is divisible into nine commas; of these, five constitute the apotome, four the limma:

or, $\frac{5}{9} + \frac{4}{9} = \frac{9}{9}$. The ratio of the limma is $\frac{243}{256}$, and for all practical

purposes it may be considered as the minor semitone of the modern scale.

LIMONIN ($C_{22}H_{25}O_{13}$?) is a bitter crystalline substance found in the seeds of lemons and oranges. It dissolves in sulphuric acid with a red colour, but the addition of water reprecipitates it.

LINE. The definition of a line, as given by Euclid, will be discussed, with other matters relating to it, in the article SOLID, SURFACE, LINE, POINT (Definitions of).

LINE. The French used to divide their inch into twelve lines, and the line into twelve points, which measures are out of date, since in all scientific investigations the metrical system is adopted. Sometimes, but rarely, the line has been divided into ten points, thus giving 1440 points to the foot: the French metrological writers, particularly the older ones, frequently give the measures of other countries in 1440ths of their own foot. Some English writers have divided the inch into lines. The French line is .0888 of an English inch, and is also two millimetres and a quarter.

LINEAL DESCENT. [DESCENT.]

LINEAR (Algebra). As all equations connected with straight lines are of the first degree, the continental writers frequently call equations of the first degree linear equations.

LINEAR DIMENSIONS. [SOLID, SUPERFICIAL, AND LINEAR DIMENSIONS.]

LINEN MANUFACTURE. Linen (French, *Tissu de Lin*; Spanish, *Tela de Lino*; German, *Linnen*; Dutch, *Lynwaat*; Italian, *Tela*; Russian, *Polotno*) is a general name for cloth woven with the fibres of the flax plant (*Linum usitatissimum*), a manufacture of so ancient a date that its origin is unknown. Linen cloths were made at a very early period in Egypt; as we see from the cloth wrappings of the mummies, which are all of this substance. It appears also that linen was, in the time of Herodotus, an article of export from Egypt. (ii. 105.) In the present day, linen as a generic term includes woven fabrics of hemp as well as flax, except the special kinds known as canvas, sail-cloth, and a few others.

England has manufactured linen from an early but unknown date. The growth of the manufacture in Ireland is ascribed to the legislative obstruction raised in the reign of William III. to the prosecution in that part of the kingdom of the woollen manufacture, which it was alleged interfered prejudicially with the clothiers of England; the linen weavers being at the same time encouraged by premiums of various kinds distributed by public boards authorised by parliament, and by bounties paid on the exportation of linen to foreign countries. It is known that linen was woven in Ireland as early as the 11th century; that Louis Crommelin, driven from France by the revocation of the edict of Nantes, established the manufacture on an improved basis; that in 1711 the Duke of Ormonde, lord-lieutenant, ordered that funeral hat-bands and scarfs should be made of linen, as a means of encouraging the trade; that a little machinery began to be applied to the manufacture in 1725; and that Dr. James Ferguson, of Belfast, greatly improved the processes by a method of bleaching adopted soon after the middle of the century. Messrs. Mulholland, of Belfast, began to spin flax by machinery in 1820. In 1828 the Linen Board was dissolved; and in 1841 a society was founded for encouraging the growth of flax in Ireland. We have no certain means for ascertaining the growth of the linen manufacture in that country. The only facts by which we can approximate to its amount are afforded by custom-house records, which do not reach back to an early date, and are wanting for the years subsequent to 1825, when the intercourse between Great Britain and Ireland was put upon the footing of a coasting trade. The average quantity of linen exported annually from Ireland, principally to England, in the three years ending March, 1790, was 34,191,754 yards; in the three years ending March, 1800, the yearly average was 36,112,369 yards; and the average annual exports in the last three years of each of the next two decennary periods was 40,751,889 yards, and 48,265,711 yards, respectively. In 1820, the quantity was 42,665,928 yards; and in 1825, it amounted to 52,560,926 yards. An estimate made by the Irish railway commissioners in 1835, put down the quantity at 70,209,572 yards of linen, the value of which was 3,730,854*l*. Since the last-named date, the means of forming an estimate have been very doubtful.

The linen manufacture was introduced into Scotland early in the

last century; and in 1727 a board of trustees was appointed for its superintendence and encouragement. Notwithstanding this and the further stimulus afforded by premiums and bounties, the progress of the manufacture in that part of the kingdom was for a long time comparatively unimportant. At Dundee, the great seat of the Scotch linen trade, the whole quantity of flax imported in 1745 was only 74 tons. In less than half a century after that time the annual importation of flax was 2500 tons, and there were exported 8,000,000 yards of linen beyond the quantity used at home. At this rate the manufacture continued nearly stationary until after the peace in 1815, when a new impulse was given to it. Improved fiscal arrangements afterwards greatly increased the production in Scotland, especially at Dundee.

In the article FLAX, an account is given of the chief processes to which the fibre is subjected in preparing it for the spinners. A very few additional details will suffice here, to show how many attempts have recently been made to supply our linen-manufacturers by home growth. All agree that some improved mode of retting is necessary to render flax-culture profitable in these islands. Russian, Prussian, and Belgian flax keep down the price of English and Irish to a point which renders the profit often doubtful. To lessen the expenses, and improve the quality in various ways, several new modes of retting have come under public notice within the last few years. The *dew-retting* and *water-retting* are described in the article above cited. The *mechanical* retting has been conducted in various ways by Lee, Hill, Bundy, Donlan, Davy, and others. It is a quick and economical process, and seems to be applicable when the crop is of too poor a character to pay for the expense of steeping; or in districts where steeping is effected with difficulty; or in cases where coarse yarns only are required. The *steam-retting* and the *hot-water-retting* are intended to effect the separation of the fibre without producing the fermentation which results from ordinary retting, with its offensive odour and its waste of substance. Schenk's hot-water process was patented in 1846, and a rettory was established in Mayo to test its value. Watts, Buchanan, and other inventors, have varied in many ways the application of heat to the process. The *chemical-retting* is founded on the same considerations as those by steam and hot-water: namely, that the dry or mechanical process is not suited to the production of fine yarn, owing to the large portion of the substance of the plant which remains attached to the fibre. The ordinary retting is in effect chemical, seeing that it is fermentation which sets free the fibre from the other parts of the plant; the hot-water and steam processes are also chemical, for they dissolve the non-fibrous portions even though they do not ferment them; but the chemical processes here adverted to are those in which alkalies or other agents are added to the water, to increase the separating effect. The systems of Lilljikeuse, Palinquist, Gay Lussac, Berthollet, Claussen, and many others, are chemical in this sense. At one time, Claussen's method attracted so much attention that 3000 acres were laid down in flax in Ireland, for conducting the process on a large scale. Some observers have thought, on comparing the results of the dry and wet processes, that the best plan would probably be to combine both—to separate the fibre from the boon roughly by a machine; to use the boon as fodder or manure; and to sell the fibre to flax preparers, who would apply a wet process for finishing it. Not only have inventors brought forward all these various projects, but numerous suggestions have in other ways been made to encourage the home growth of flax. The British government has not recently offered any direct bounty or encouragement for the growth of flax; but the New Zealand government, in 1856, offered 4000*l*. in various sums as prizes to persons who would produce New Zealand flax good enough and cheap enough to encourage the colonists to attend to this branch of industry. As to joint stock companies, many have been suggested in reference to flax growing and manufacture. One was proposed in 1859, to work out Cator's plan; the objects of which were to encourage the growth of flax at home, to buy the plants, to establish rettories, to ret the flax to a certain stage, and sell it to the spinners—thereby relieving the grower, as an agriculturist, from all the mechanical and chemical difficulties of retting. Notwithstanding all these efforts, however, the home growth of flax makes slow progress. Ireland had 50,000 acres under flax in 1812; this rose to 110,000 in 1826; a gradual decline brought it down to 58,000 in 1847; it rose again to 170,000 in 1853; since which year it has fluctuated greatly. Taking the whole of the United Kingdom, we did not in 1858 grow one-fourth of the flax required by our spinners. The Irish produce seems to be about 6 cwt. of clean fibre to the acre.

Until recently little machinery was used in the production of linen cloth. After the separation of the ligneous fibre of the plant, the distaff and common spinning-wheel were employed for the preparation of the thread or yarn; and the hand-loom generally, in its simplest form, was used for weaving the cloth. Within the present century the first attempts were made at Leeds to adapt the inventions of Hargreaves and Arkwright to the spinning of flax. Mill-spun yarn is now universally employed by the linen-weavers of this kingdom for the production of the very finest lawn, as well as of the coarsest linen; and of late years the use of the power-loom has been adopted for weaving all but the very finest and most costly fabrics. These improvements have rendered this country independent of all others for the supply of linen yarn of every quality, and diminished in a most important degree

the cost of linen fabrics; so that British yarns and cloths are now profitably exported to countries with which the manufacturers of Great Britain and Ireland were formerly unable to compete, and against which they were protected in the home market by high duties on importation.

Of the flax-spinning mills there is one at Leeds, belonging to Messrs. Marshall, which ranks among the largest factories in the world. One particular room is, we believe, the largest in existence devoted to manufacturing purposes; it covers two acres of ground, the roof is supported by fifty pillars, and lighted by sixty-six large conical skylights.

The flax reaches the spinning-mills in small bundles of a few pounds

each. The fibres are first *scutched* out at the ends, by a machine which subjects them to a sort of combing action. They are then *broken* into three pieces each, the middle section being the best in quality. They are next *heckled*, or separated, straightened, and cleaned; this used formerly to be done with the heckle, a sort of large comb with iron teeth; but it is now effected by a rotating machine, on the periphery of which the flax is fixed, and drawn against or between a series of sharp teeth. The fibres pass through six heckling machines in succession, each having finer teeth than the one which preceded it. The heckled flax is then sorted into portions, according to fineness and other desired qualities. The next process, that of *drawing*, connects the short fibres of flax into one continuous sliver or riband, nearly in the

Fig. 1.—Flax Drawing.

same way as the carding process described in COTTON MANUFACTURE; the flax is doubled and carded over and over again, until it presents the appearance of a smooth and glossy band, about an inch in width. When flax has been so far prepared, all the good portion receives the name of *line*; while the irregular, short, and defective fibres become *tow*. The tow is, however, susceptible of being drawn, doubled, carded,

hemp. The heckled slivers of flax are next *roved*, or converted from a flat riband to a soft small cylindrical cord. The *spinning* is the next process; this is done on the bobbin and fly principle, and the flax requires to be wet while under the process, thereby differing from cotton, wool, and silk. The flax used formerly to be wetted with cold water; but it is now found that finer yarn can be produced when

Fig. 2.—Tow Carding.

and spun into yarn of coarse quality. This tow is not the very rough substance usually known by the name; the latter is the refuse of

Fig. 3.—Wet Flax Spinning.

warm water is used. The essential parts of the apparatus are shown in skeleton in fig. 3.

The spun yarn is applicable either for making thread or for weaving into linen goods. The quality of flax yarn is denoted by numbers describing the numbers of *leas* (a measure of 300 yards) contained in each pound weight. Thus a pound of No. 60 yarn measures 60 leas or 18,000 yards; No. 5 has only 1500 yards to the pound; while No. 200 has as much as 60,000 yards. Flax yarn is seldom spun of greater fineness than No. 200, which is fitted for making cambric of good quality. The improvements effected in the manufacture have greatly increased the average fineness and lowered the price.

More flax is spun in Leeds than in any other town; but the weaving is carried on elsewhere. In and around Barnsley are woven linen, duck, check, drab, tick, huckaback, diaper, drill, towelling, and other kinds of flax goods. Dundee is famous for sailcloth, dowlas, sheeting, and other strong textile goods; and Aberdeen is taking up a position in the same department. Dunfermline and its vicinity produce finer fabrics, such as shirtings, damasks, and table-cloths. Belfast is the great

centre for good linen, and for the finer kinds of textile goods. Of these, duck is made in widths from three to five quarters of a yard; drill is a twilled linen, white or coloured, mostly used for summer trowsers; sheetings are known in the trade by the names of Irish, Russia, Imitation Russia, Lancashire, Yorkshire, Union Irish, and Union Lancashire, (the union cloth having a mixture of cotton with the flax); some of the sheetings are mostly or partly of hemp; damask is noticed under DAMASK; diaper is a figured fabric of lower quality; huckaback is a durable and economical kind of towelling. The best cambric is imported from France. Silesia is a sort of fine holland, used for window blinds. It may be stated here that many of the above-named fabrics are made either of flax or of hemp, according to the prices at which they are to be sold. The broad and well-made fabric for sailcloth is dressed with starch or flour before weaving, by the machine shown in the annexed cut; indeed most kinds of flaxen and hempen fabrics require some such dressing. The wet yarn, by passing over

Fig. 4.—Dressing Yarn for Sailcloth.

and under two steam-heated metal boxes, becomes very quickly dried.

The statistics of this trade divide themselves into three parts, relating to the seed, the fibre, and the woven goods. About 4,000,000 bushels of linseed are imported annually; one-fifth for sowing into a flax-crop, and four-fifths for pressing linseed-oil. Three-fourths of the whole supply is from Russia; the sowing-seed is very carefully prepared, and is imported in casks officially branded; but the crushing-seed is coarser, and is imported either in bulk or in mat-bags. The flax imported in 1844 was about 1,600,000 cwts., in 1850 about 1,800,000 cwts., and in 1858 about 1,300,000 cwts.; the quantity varying considerably in different years. The price has varied still more widely, depending chiefly on the Russian crops. The computed value of the seed and fibre imported in 1858 was 2,700,000*l.* The woven linen goods, taking that term in its widest acceptation in reference to kind and quality, varied from 14*d.* to 21*d.* per yard on an average in the years for 1835 to 1853; in later years it has generally been near the lower of these two limits. In respect to woven goods, the bounties allowed on the shipment of linens were graduated according to their quality and value, and ranged from a halfpenny to a penny halfpenny per yard. In 1825 the rates were diminished one-tenth by an act then passed, and an equal proportion was to have been taken off in each subsequent year, so that the whole would have ceased in 1834; but by the act of 1828, when one-half the bounties had been removed, this course was modified by continuing for three years the rates of allowance payable in 1829, and thereafter repealing the bounty altogether; so that the payments ceased in 1832. Since then the export trade has rested on its own resources. In 1828 the declared value of the exports of these goods was 2,100,000*l.*; in 1837 it was 2,500,000*l.* In 1844 the exports (white or plain linen, printed and dyed flaxen goods, sailcloth, thread, and yarn) reached a value of 4,000,000*l.*; in 1850, 4,800,000*l.*; and in 1858, 5,900,000*l.* The quantities in the last-named year were, 120,000,000 yards of piece goods, and 35,000,000 lbs. of thread and yarn. The import of woven flaxen goods is very small. The export to France steadily increased until 1842, in which year the French government, influenced by a demand for protection, raised the import duty considerably; and the English trade in this commodity has suffered ever since. The flax and linen manufacturers of England are hoping for an extension of their dealings with France, consequent on the new treaty of commerce (1860). The number of mills and operatives engaged in this trade, in the United Kingdom, is noticed under FACTORIES.

LINES, in Music, are the five parallel lines forming, together with the intermediate spaces, the staff on which the notes and other characters are placed. [STAFF; LEGER.]

LINES OF INTRENCHMENT. In the article ENCAMPMENT it has been stated that armies in the field are not now, as formerly, surrounded by fortifications consisting of a continuous line of works;

and that, in general, a few breastworks or redoubts merely are constructed at intervals for the defence of the position. It will be sufficient, therefore, leaving out the consideration of those means of defence which are afforded by the natural obstacles of the country, as escarpments, rivers, marshes, &c., to describe briefly the nature of those intrenchments which were once, in all circumstances, considered indispensable, and which are still, to a certain extent, necessary when an army is to remain strictly on the defensive.

In the first place it may be said that a continuous breastwork would be advantageous for the protection of portions of a frontier, when the absence of natural obstacles might favour the enemy's marauding parties in making inroads for the purpose of levying contributions or laying waste the country; a parapet *AB*, broken by the redans *c, c*, from whence the defenders may annoy the enemy in flank on his

approach, termed a Redan Line, is the simplest form. The distances of the redans from one another may be about 150 yards, or not exceeding the range of musket shot: such was the construction recommended by Vauban, and since his time, it has been modified occasionally by giving to the curtains the form indicated by the lines *a c, b c*, in order that the ditch might be more effectually defended from the faces of the redans. All the faces should be so disposed that, if produced to an extent equal to the range of artillery, the lines of direction may fall on ground where the enemy could not establish batteries for the purpose of enfilading them; since, in the event of such enfilading taking place, the defenders would be compelled to abandon the parapets; artillery, if placed there, would be dismounted; the palisades in the ditch would be destroyed; and little resistance could be made, should the enemy subsequently assault the line. In general the redans may have the form of equilateral triangles, and the lengths of their sides may be about 50 yards. The entrances are usually in the middle of the curtains.

Instead of simple redans the advanced parts of the line have occasionally been formed of works resembling two united together, as *D*; which by the French engineers are called *queues d'hyrondes*, or double redans.

Again, when the nature of the ground does not permit the intrenchment to be formed with points so far advanced as the vertices of the redans *c, c*; when, for example, it is required to follow a bank of a river or one side of a road, it is proposed, in preference to a simple straight or curved line, to form the parapet with a series of branches in the positions indicated by *a b, c d*, &c., to *P*. A line of this kind is said to be à *crémaillères*: and in such situations a succession of fires from the branches *a b, c d*, &c., may be directed against the enemy

during his advance; on a level plain however the longer branches would be subject to the serious defect of being easily enfiladed. The

yards. The re-entering angles *a*, *e*, &c., should contain about 100 degrees; and the entrances are usually placed at those points.

A like construction may be adopted when it is required to connect two points, as M and N, by a line along a narrow and elevated ridge of ground; and in this case the directions of the branches *b c*, *d e*, &c., may change in the middle of the line, as shown in the figure, in order that the fire from the long branches may be directed to the front of the nearest works, as M and N, in which it is to be supposed that artillery would be placed for the purpose of defending the ground before the intermediate line.

It may be added also, that the line à crémaillères (indented line) is convenient when it is required to join forts on hills or rising ground.

The most perfect fortification for defending a line of country presenting few natural obstacles to the advance of an enemy, should the importance of the position render it advisable to incur the labour of the construction, would be a series of bastions connected by curtains, either straight or broken. The principles on which the several fronts of fortification should be formed correspond to those adopted for regular fortresses, which are described in the article FORTIFICATION; the only difference being in the lengths of the several parts. These depend upon the whole length of the front, which here should not exceed 180 yards, that the ditches of the bastions may be well defended by common muskets from the collateral flanks. Neither ravelin nor covered-way would of course be necessary.

Lines of intrenchment composed of works placed at intervals from one another, provided the distances be not so great as to prevent the troops in them from mutually assisting each other, have great advantages over those formed of continuous lines of parapet. In the latter case it is scarcely possible for the army to make a movement for the purpose of attacking the enemy however favourable the opportunity, since much time would be lost in issuing from the line through the narrow passages; and as these are the objects against which the fires from the enemy's batteries would then be incessantly directed, it would be almost impossible to form any extended front for attack; besides which, the enemy penetrating at any one point the whole line is turned. Detached works, on the other hand, constitute a number of strong points by which the position of the army is secured; while through the spacious intervals an advance or retreat may take place with the utmost facility. Their artillery is conveniently situated for putting the enemy's line in disorder previously to the attack, and for protecting the retiring columns in the event of their quitting the field. It may be added that detached works are capable of being easily adapted to any kind of ground; for it is merely necessary to place them on the more elevated spots in such situations that the enemy may not be able to penetrate between them without being exposed to their fire.

On level ground the intrenchment may consist of a number of redans, as A, B, C, with or without flanks, disposed on a right line or curve, and at distances from one another equal to about 300 yards,

that the fire of musketry from them may defend the intervals. In the rear, and opposite the intervals between the works in the first line, a second line of works, as D, E, should be formed; and the faces of these should be disposed so as to flank the ditches and approaches to the others. The gorges of the exterior works should be open, as in the figure, or only protected by a line of palisades, which, in the event of the enemy gaining possession of those works, might be destroyed by the artillery in the second line.

Instead of a series of redoubts forming an interior line, it may suffice, should the works A, B, C, &c., be disposed on a convex arc, to have one large central redoubt as F, so situated as by its artillery to

distances between the salient points *b*, *d*, &c., should not exceed 100 yards, and the lengths of the short branches may be about 18 or 20

defend both the intervals between the redans and the ground within their line.

All the works which have been described consist of parapets formed of earth obtained by cutting a ditch in front; and the profile of any one work with its ditch is shown in the subjoined figure (4).

The elevation of the crest A above the natural ground is about 7½ feet, unless the vicinity of a commanding height in front should render a greater relief necessary, and the depth of the ditch may be the same. The thickness A a of the upper part of the parapet is variable, and depends upon the importance of the work, or rather, upon the arm which may be employed in the attack; if it were required only to resist a fire of musketry, 3 feet would suffice; but from 8 feet to 12 feet would be necessary in the event of artillery being brought against it. (Twelve-pounder shot is the heaviest which the French have ever yet employed in the field.) The form of the parapet is the same as in permanent fortification; when time permits, the exterior and interior slopes should be revêted with sods, and a line of palisades should be planted along the foot of the counterscarp.

LININ, a crystalline substance of unknown composition found in the mountain flax (*Linum catharticum*).

LINOLEIC ACID. [OLEIC ACID.]

LINOLEIN. [OLEIC ACID.]

LINSEED (*Graine de Lin*, French; *Leinsaat*, German; *Lynzaad*, Dutch; *Linaza*, Spanish; *Linhaca*, Portugal; *Linseme*, Italian; *Sem-jalenjanve*, Russian), the seed of the Lin, *Linum*, or flax plant, is a valuable product derived from the capsules of *Linum usitatissimum*, and consisting of small grayish-brown lenticular bodies, containing a mealy albumen, of so oleaginous a nature, that it yields by pressure in great abundance the oil of linseed. The seed of the flax-plant is harvested not merely with a view to the reproduction of the plant, but also because of the oil which it yields by compression. For both these purposes, of sowing and crushing, linseed is largely imported into the United Kingdom. [LINEN MANUFACTURE; FLAX.] It is largely used now as cattle food—and the refuse, after its oil has been expressed, is the well-known oilcake of the cattle feeder.

LINSEED-OIL may be procured by cold expression of the seeds, a process which makes the oil clearer; or the bruised seeds are roasted in the oil-mills, in which case it is brownish-yellow, and easily becomes rancid, probably from attracting oxygen. Linseed-oil is pellucid, with a faint but peculiar odour and taste, generally disagreeable, from being subrancid. Specific gravity 0.93. It easily dries: by reduction of temperature it merely becomes cloudy, but scarcely freezes.

It may easily be purified by repeated agitation with water, by bleaching in the sun, or, better, by filtering it through newly prepared charcoal.

By long boiling it becomes dark-brown, tenacious, and thickened, but dries more easily, and in this state is used for printers' ink; by still longer boiling it becomes black, almost solid, and elastically tenacious, like caoutchouc, and in this state it serves for bird-lime.

By the addition of nitrous acid it becomes thick and red, then dark reddish brown, like tincture of iodine, but does not become solid. It is frequently adulterated with rape oil, which may be detected by this test. Neither does it form elaidin, as rape-oil does. But a simpler test is, that if wood be smeared with oil which has been adulterated, it does not become dry.

Linseed-oil is used to form liniments, of which the most common is that with lime-water, as an application to burns. But it is much more extensively used in the arts, particularly for painting. It is mildly laxative.

LINT. [LINUM USITATISSIMUM.]

LINUM USITATISSIMUM, *Medical Properties of*. The seeds of this plant yield several articles useful in medicine and surgery. The testa, or husk of the seeds, is very mucilaginous, the kernel contains much oil, and the farina or meal, procured by grinding or bruising the seeds, after the oil has been expressed, furnishes an excellent material for poultices, but now greatly superseded by Spongiopiline. [CATAPLASMS.] The seeds are oblong-ovate, acute, compressed, brown, shining, very smooth, the skin thin, the kernel white and oily. They are devoid of odour, but have an unpleasant mucilaginous oily taste. Old, rancid, and corroded seeds should be rejected. One part of seeds and two parts of water yield a strong mucilage. It is much better to

obtain the mucilage by merely pouring cold water on the entire seeds, than to bruise them and pour boiling water on them, as generally directed. The mucilage is analogous to that of the quince seed [CYDONIA in NAT. HIST. DIV.], and differs in its chemical habitudes, in several respects, from common gum. The compound infusion of linseed is demulcent, and the unpleasant taste may be much lessened by using cold water to form it, as stated above. The farina of the seeds, ground before the oil has been expressed, furnishes the best material for poultices, but does not keep well. The cake remaining after the expression of the oil is much used to fatten cattle, but gives a peculiar taste to the meat.

The lint, or charpie, used by surgeons to dress ulcers, &c., should always be prepared from linen-cloth and never from cotton, as an essential difference exists in the nature of their fibres, which causes that of cotton to prove extremely irritating.

LIP. [HARE LIP.]

LIPIC ACID. [SUCCINIC ACID.]

LIPRYL, a name formerly applied to the radical of glycerin. [GLYCERIN.]

LIQUEFACTION. When heat is supplied in sufficient quantity to a solid body, it changes its form and becomes liquid. When this change takes place in the case of ice the process is called *liquefaction*, but in the case of metals *fusion*. So also if heat be abstracted in sufficient quantity from a liquid, it usually becomes solid, which process, in the case of bodies which under ordinary circumstances are liquid, such as water, oil, &c., is called *congelation*; but for bodies which are usually solid, such as the metals, the process is called *solidification*.

The more important phenomena attending liquefaction are stated under LATENT HEAT. [See also FREEZING MIXTURES; HEAT.] Bodies require very various amounts of heat for liquefaction. Mercury, for example, fuses at 39° below zero, wrought iron above +3280°. The following table contains the fusing points of the substances named:—

Names of Substances,	° Fahr.	Authority.
Mercury	−39	Hutchins.
Oil of vitriol	−30	Regnault,
Bromine	+ 9.5	Pierre.
Ice	32	
Phosphorus	111.5	Schrötter.
Potassium	136	Regnault.
Yellow wax	143.6	Person.
Sodium	207.7	Regnault.
Iodine	224.6	Gay Lussac.
Sulphur	239	
Tin	451	
Bismuth	512	Person.
Nitrate of soda	591	
Lead	620	
Nitrate of potash	642	
Zinc	773	
Antimony (about)	900	
Silver	1773	Daniell.
Copper	1996	
Gold	2016	
Cast-iron	2786	
Wrought-iron	above 3280	

The fusing points of alloys are often much lower than the fusing point of either of their components. An alloy of two parts bismuth, one of lead, and one of tin, fuses at 200°. The alloy of eight parts bismuth, five of lead, and three of tin, fuses a little below 212°: the addition of one part mercury renders it still more fusible. It is a very convenient substance for taking casts. When this *fusible metal*, as it is called, is poured upon a marble slab, and broken as soon as it is cool enough to be handled; its surfaces are bright and conchoidal, but the metal is very brittle. Soon, however, it becomes very hot, ceases to be brittle, and the fractured surface becomes granular and dull; this change of temperature must arise from some new molecular arrangement of the particles after solidification; it does not appear to be due to the evolution of latent heat, arising from the solidification of the interior after that of the exterior crust, as has been suggested. The metal after falling to 90° has been known to rise to 150°. The use of fluxes by the metallurgist and others affords numerous illustrations of the fact that mixtures of various bodies fuse at lower temperatures than their component parts do separately. Mixtures of various salts illustrate the same fact:—thus, nitrate of potash fuses at 642°, nitrate of soda at 591°, but a mixture of the two salts in equivalent proportions liquefies as low as 429°.

Under the combined influence of pressure and cold most of the gases have been liquefied and even solidified as noticed under GASES, LIQUEFACTION OF.

LIQUEFACTION OF GASES. [GASES, LIQUEFACTION OF.]

LIQUIDITY is that condition of a material substance in which the particles have a perfect freedom of motion, without any sensible tendency to approach to or recede from one another, except by the action of some external power. Liquidity is therefore comprehended in the condition of fluidity, the latter term being applied as well to gases, and even to the principle of electricity, magnetism, &c., as to water, oil, &c., which are properly called liquids. [FLUID; FLUIDITY.]

The phenomena of capillary or molecular action show that the attractions which constitute what are called the *affinities* of substances extend to very small distances only from the particles; and hence, when the particles of a substance are situated beyond the limits of such attractive forces, the repulsive power, arising probably from the action of caloric, causes the particles to recede continually from one another, and induces the state of aeriform fluidity. [ATTRACTION.] Now the phenomena of crystallisation seem to indicate that the attraction of affinity is exerted with greater or less intensity according as the like or unlike sides of the particles of a substance present themselves to one another in their mutual approaches; but it is probable that this modification of the attraction of affinity extends to less distances from the centres of gravity of the particles than the general attraction extends: hence, when the particles of a substance are, from any cause, brought so near one another that the attraction of affinity is in equilibrium with the repulsive force of the caloric, and at the same time the modification of that attraction caused by the various positions which the particles assume in approaching one another, entirely or nearly vanishes, it should follow that the particles become freely moveable in any direction about one another, whatever be their form; and thus may arise the condition of liquidity.

It may be added that, if the particles of a substance be, by the abstraction of caloric, made to approach still nearer to one another, the attraction of affinity will exceed the force of repulsion; and there will be constituted a solid body, which may be crystallised or not according as the particles approach one another gradually or otherwise: in the former case they may arrange themselves in such positions as to become connected together in one direction by the sides at which the attraction is the greatest; while, if the approach is rapid and is accompanied by agitation, the union of the particles may take place irregularly.

The particles of a liquid are held together with considerable force notwithstanding their freedom of motion, since a small quantity of a liquid has a tendency to take a spherical form when at a distance from any substance for which its particles have greater affinity than for one another: this is very evident in mercury, oil, and water, the first of which on being suffered to fall on a table immediately divides itself into globules, and the others take a like form when a small quantity of either is suspended from a pointed extremity of any object.

The dilatations of water and mercury by the application of heat, as well as the remarkable fact that the expansions of water are equal at temperatures which are at equal distances above and below about 39° Fahr., will be noticed under THERMOMETER. See also HEAT. But the expansions of any liquid, at different temperatures, for equal increments of caloric, are not equal to one another; and indeed the same remark may be extended to solids, as shown under HEAT. The phenomena of molecular action in liquids are noticed under CAPILLARY ATTRACTION, DIFFUSION, &c. See also MOLECULAR ATTRACTION, and for the specific heat of liquids, or their capacity for caloric, SPECIFIC HEAT.

LIQUOR OF CADET. [CACODYL.]

LIQUORICE. [GLYCYRRHIZA.]

LIRIODENDRIN, a colourless, non-azotised, crystalline substance, found in the stem of the Virginian tulip (*Liriodendron tulipifera*). It is slightly soluble in water, but very soluble in alcohol and ether. Its composition has not been determined.

LIS PENDENS. [NOTICE.]

LIST, CIVIL. [CIVIL LIST.]

LISTING. [ENLISTMENT.]

LITANY, a collection of prayers and supplications. The term is derived from the Greek (*λειτουργία*), and was adopted by Christian writers at a very early period. St. Basil tells us that Litanies were read in the church of Neocæsarea, between Gregory Thaumaturgus's time and his own: and St. Ambrose has left a form of Litany which bears his name, still used in Milan. In the early churches the Litanies were said in solemn procession.

In the Common Prayer Book of 1549 (the first book of King Edward), the Litany was placed between the Communion Office and the Office for Baptism, under the title of 'The Letany and Suffrages;' which book also directed it to be said or sung on Wednesdays and Fridays. In the review of the Common Prayer in 1552, the Litany was placed where it now stands, with the direction that it shall be used on Sundays, Wednesdays, and Fridays, and at other times when it shall be commanded by the ordinary. Till the last review, in 1661, the Litany was used as a distinct service, and followed the Morning Prayer; it was then directed and has ever since continued to be read as one office with the Morning Prayer, after the third Collect for Grace.

LITHARGE. [LEAD: Lead and Oxygen.]

LITHIA (LiO). The alkaline base formed by the union of lithium with oxygen. It unites with acids to form an extensive class of salts. [LITHIUM.]

LITHIC ACID. [URIC ACID.]

LITHIUM (L). In its chemical relations this metal more nearly resembles the alkali metals, potassium and sodium, than any others; but it is a kind of connecting link between that group and the next, or metals of the alkaline earths (barium, calcium, &c.) Its existence was first pointed out by Arfwedson (1817), who discovered its oxide when examining a mineral in the laboratory of Berzelius. Its name is

derived from *λίθος*, a stone, it having been found in the mineral kingdom only.

The principal sources of lithium are the minerals *lepidolite*, *triphane*, and *petalite*. A table of their per-centage composition is given under the respective names in the NAT. HIST. DIV. Their formulæ is thus represented in Miller's 'Elements of Chemistry':—

Lepidolite or lithia mica .	2[(LK) Fl] + 4(Al ₂ O ₃ , 3 SiO ₂)
Triphane or spodumene .	3[(LNa)O, SiO ₂] + 4(Al ₂ O ₃ , 3SiO ₂)
Petalite	3[(LNa)O, 2SiO ₂] + 4(Al ₂ O ₃ , 6SiO ₃)

Lithium may be obtained in the metallic state by decomposing its chloride with an electric current generated from five or six pairs of Bunsen's nitric acid battery. It is a white metal, harder than potassium or sodium, but softer than lead. It melts at 356° Fahr., and is not volatile when heated to redness. At common temperatures two pieces may be welded together by pressure. It can be drawn into wire, but is less tenacious than lead. Its specific gravity is 0.5936, hence it is the lightest solid body known; it floats even on the surface of naphtha. It rapidly oxidises in the air, and if assisted by heat burns with a brilliant carmine-tinted flame. It decomposes water in a similar manner to sodium, and ignites when placed in strong nitric acid.

The equivalent of lithium is 6.53.

Lithium and oxygen form but one compound, namely:—

Oxide of lithium (LO). The mineral from which it is to be extracted is reduced to an almost impalpable powder, and then ignited with twice its weight of quicklime in a silver crucible. The resulting mass is next treated with hydrochloric acid, then with sulphuric acid, and the sulphate of lithia thus formed dissolved out from sulphate of lime by washing with water; a small quantity of oxalate of ammonia is now added to remove lime that may have been dissolved, and sulphuric acid thrown out of solution by the addition of baryta water. On evaporating the filtered liquid the lithia separates out in grains. If necessary, it may be fused in a silver crucible, vessels of platinum being rapidly corroded by it.

Hydrate of lithia is not so soluble in water as the hydrates of potash or soda are. It has a strong caustic taste, and turns vegetable reds to blues. In the fused state it is white, transparent, has a crystalline structure, does not deliquesce in the air, and dissolves in water with disengagement of heat.

Lithium and chlorine form:—

Chloride of lithium (LCI). It is readily made by dissolving the oxide in hydrochloric acid. On evaporation the solution yields cubical crystals, very soluble, exceedingly deliquescent, and containing four equivalents of water of crystallisation.

Iodide of lithium (LI + 6HO) crystallises in needles, and *fluoride of lithium* in small opaque grains.

Sulphide of lithium is formed in the same way as sulphide of sodium, and much resembles that compound.

Sulphate of lithia (LO, SO₃ + Aq). On evaporating the solution of this salt, obtained as described under *oxide of lithium*, tabular crystals of the above composition are obtained.

Carbonate of lithia (LO, CO₂) is precipitated when carbonate of ammonia is added to a strong solution of chloride of lithium. It may be washed with alcohol, in which it is insoluble. It is slightly soluble in water, the resulting solution having an alkaline reaction. On the application of heat to the dried salt it fuses, and solidifies on cooling to a white transparent mass of pearly lustre and crystalline fracture.

Carbonate of lithia has been recommended to be administered as a solvent for calculi in the bladder. It certainly effects the solution of uric acid most rapidly when triturated with that substance in a mortar containing a little water; but as many calculi do not contain uric acid, and as most of those that do contain it have an external coating of phosphates, it follows that the carbonate of lithia, being an alkaline substance, may do more harm than good if administered indiscriminately.

Double phosphate of lithia and soda.—When phosphate of soda is added to a solution of a lithium salt no precipitate is at first produced; but on evaporating to dryness the above compound remains as a white powder, almost insoluble in water, and quite insoluble in dilute aqueous solutions of the alkaline phosphates. Before the blowpipe, with carbonate of soda, the double salt fuses to a clear bead, transparent when hot but opaque when cold. A fused specimen examined by Berzelius contained NaO, LO, PO₃, but generally its composition is very variable, probably on account of the two bases, lithia and soda, being capable of replacing each other.

Tests for lithium.—Salts of lithium are readily fusible in the blowpipe flame, imparting to it a carmine red colour, and attacking the platinum wire holder or other platinum vessel in a characteristic corrosive manner. Their presence is further confirmed by forming the carbonate and double phosphate in the way already mentioned.

LITHOFELIC ACID. (C₄₀H₃₆O₈). *Lithofellinic acid*. The once celebrated *bezoar-stones*—intestinal calculi of certain animals—almost wholly consist of this acid. To isolate it, the stones [BEZOARS], are reduced to powder and boiled in alcohol, the dark solution decolorised with animal charcoal and evaporated, when the lithofellic acid crystallises out in small, colourless, transparent six-sided prisms. It may also be decolorised by precipitating its alkaline solution with hydrochloric acid, washing, drying, and crystallising from alcohol.

Lithofellic acid is insoluble in water, slightly so in ether, and very soluble in alcohol. Heated to 401° Fahr. it melts, and at a little higher temperature is converted into a resin, the fusing point of which is only 230° Fahr. In this particular, and in the fact that it is readily soluble in solutions of the alkalies and their carbonates and in acetic acid, lithofellic acid is easily distinguished from cholesterolin, a body that otherwise it much resembles.

Submitted to dry distillation, it yields an oily acid, termed *pyrolithofellic acid* (C₄₀H₃₄O₆).

Lithofellic acid combines with bases to form *lithofellates*, a class of compounds that have not been much studied. The silver salt appears to contain C₄₀H₃₅AgO₈.

LITHOGRAPHY, the art by which impressions or prints are obtained by a chemical process from designs made with a greasy material upon stone. It has therefore been properly termed chemical printing, to distinguish it from all other modes of obtaining impressions, which are mechanical. In printing from an engraving on a copper or steel plate, the ink is delivered from the incisions made therein with the graver or etching-needle. An engraving on wood, on the contrary, gives its results from the projecting surface of the block, or those parts which are not cut away by the graver. The lithographic process differs from both these modes, the impressions being obtained (by strict attention to chemical affinity) from a level surface. The art of lithography was first practised by the inventor Alois Senefelder, in 1798, the peculiar property on which it depends having being discovered by him a few years earlier. [SENEFELDER, ALOIS, in BIOG. DIV.]

There are various styles of lithography, as will presently be seen; but the principle of the art is uniformly the same, being, as we have said, based upon that of chemical affinity.

The stone best calculated for lithographic purposes is a sort of calcareous slate, found in large quantities on the banks of the Danube in Bavaria, the finest being that found at Solenhofen, near Munich. Stones much resembling the German have been found in some parts of Devonshire and Somersetshire, and also in Ireland; but the stones found in this kingdom have been proved to want some of the essential qualities of those brought from Germany, which are therefore, at least for artistic works, exclusively used. Even the Bavarian stones vary much in quality, all the strata not being equally good: some are too soft, and others are rendered unfit for use by the presence of chalk, flaws and veins, and fossil remains. A good stone is porous yet brittle, of a pale yellowish-drab, and sometimes of a gray neutral tint. The stones are split or sawn into slabs varying from 1½ to 3 inches in thickness, which are then cut or squared into the different sizes necessary for use, and the face or upper surface of each is made level. In this state are the stones sent from the quarry; but further preparation is yet necessary to fit them for the immediate use of the artist, and they are either grained or polished, according to the nature of the work they are intended to receive. The mode of preparing a grained stone, as it is called, is this:—A stone, being laid flat on a table, has its surface wetted, and some sand sifted over it through a very fine wire-sieve. Another stone is laid with its face downwards upon this, and the two are rubbed together with a circular motion, to produce the requisite granulation, which is made finer or coarser, to suit the taste or intention of the artist. The stones thus prepared are used for drawings in the chalk manner, or for imitations of those produced with the black-lead pencil. Great care is requisite in this mode of preparation, to keep the granulation uniform and the surface free from scratches, the presence of which would otherwise much disfigure the future work. Writings, imitations of coloured drawings, etchings, pen and ink sketches, &c., require the face of the stone to be polished, which is effected by rubbing it with pumice-stone and water, or pumice stone dust and water applied with rags.

The two principal agents used for making designs, writings, &c., on stone, are called lithographic chalk and lithographic ink. They are composed of tallow, virgin-wax, hard tallow soap, shell-lac, sometimes a little mastic or copal, and enough lampblack to impart a colour to the mass. These are incorporated by a peculiar process of burning in a closely-covered saucepan over a fire, and the whole is ultimately cast into a mould, and receives the form calculated to fit it for use. The ingredients are the same in the chalk and the ink, but the proportions are varied, and a little Venice turpentine is often added in the latter. The chalk is used as it comes from the mould in a dry state, but the ink is dissolved by rubbing, like Indian ink, in water, and is used in a pen or camel-hair pencil. It will be perceived that it is the presence of the soap in this greasy material which renders it soluble in water.

To render the lithographic process intelligible, let it be supposed that the artist now completes a drawing with the chalk just described, upon a grained stone, much as he would make a drawing in pencil or chalk upon paper. If, while in this state, a sponge filled with water were passed over the face of the stone, the drawing would wash out, the chalk with which it is made being, as we have seen, soluble in water, by reason of the soap which it contains. Before therefore it is capable of yielding impressions, a weak solution of nitrous acid is poured over it, which unites with and neutralises the alkali or soap contained in the chalk, and renders it insoluble in water. After this the usual course is to float a solution of gum over the whole face of the

stone, and when this is removed, if a sponge and water be applied to its surface, as before supposed, the drawing is found to be no longer removable, because the chalk with which it is executed is now no longer soluble in water. In this state the work is ready for the printer, who obtains impressions by the following process.

Having with a sponge filled with water, to which an extremely small quantity of acid has been added, wetted, or rather damped, the whole surface of the stone equally, the printer finds that the water has been imbibed by the stone only on those parts not occupied by the drawing, which being greasy repels the water and remains dry. A roller properly covered with printing-ink is now passed over the whole stone, which will not even be soiled where it is wet, from the antipathy of oil and water. But the parts occupied by the drawing being, as we have seen, dry and greasy, have an affinity for the printing-ink, which therefore passes from the roller and attaches itself to the drawing. In this state it is said to be charged, or rolled in. Damped paper is then put over it, and the whole being passed through a press, the printing-ink is transferred from the stone to the paper, and this constitutes the impression. By repeating in this manner the operations of damping the stone and rolling in the drawing, an almost unlimited number of impressions may be obtained.

Now, as we have said, the modes of lithography are various, but the illustration just given will explain the principle of them all. It consists in the mutual antipathy of oil and water, and the affinity which the stone has for both, that is, in its power of imbibing either with equal avidity. But, as will be inferred, to ensure complete success, great nicety is requisite in the preparation of all the agents employed in this art, and in the process of printing, as well as in making the drawing on the stone.

Imitations of etchings or pen and ink drawings, writings, &c., executed with the chemical ink upon a polished stone, are prepared and printed in precisely the same manner.

Transfer lithography, or *Autography*, from the facility of its execution and its great utility, claims especial notice. A paper called *transfer-paper* or "autographic paper," is used to receive the writing in this mode of lithography. This paper has previously had a liquid gummy preparation washed over one side of it, which, when dry, constitutes its face, and the writing being performed with a modification of the chemical ink already described, rests upon this gummy surface, and does not penetrate to the paper beneath. When the writing or drawing done on the transfer-paper is dry, the back of it is wetted slightly but equally with a sponge and water; and the paper being very thin, the gum preparation on the front of it becomes at once partially dissolved. In this state the paper is laid, with its face downwards, on a polished stone, and being passed through a press, the transfer-paper is found strongly and closely adhering to it. The back of the transfer-paper is now well wetted, and, one corner being first raised, it will readily peel off, leaving the gum preparation, and of course also the writing which was above it, attached to the stone. The gum is then washed off with water, and the preparation and printing proceed in the manner already explained. This mode of lithography being eminently calculated to facilitate the despatch of business, its great utility has been sensibly felt in the commercial departments of the country and in several of our government offices, as by its means one written despatch can be multiplied at pleasure, without delay or the risk of typographical errors.

Another style of lithography is commonly called "*etching*," or "*engraving on stone*," although it must by no means be inferred that in this process the stone is incised, but that the results correspond with the clean-cut lines of the graver or etching-needle. A coat of gum-water, with some lamp-black or vermilion mixed with it, to give it colour and render the work visible, is thinly but evenly rubbed over a polished stone, and, when dry, effectually protects it from any application of grease. On this gum ground the design is executed with an etching-needle, precisely the same as in etching upon copper; and wherever the needle passes, of course the stone is laid bare, and it is best to cleanly remove the gum ground without cutting into the stone. After this some oil is rubbed over the whole surface, and is imbibed by the stone wherever the needle has passed and exposed its surface by removing the ground. The gum is then washed off, and the work may be at once rolled in and printed, without any previous acidulation.

Thus we see that grease anyhow applied to the stone will yield impressions, but that the character of the impression depends, 1st, on the *quality* of the grease; 2dly, on the *quantity* of grease; and 3dly, on the manner in which the grease is *applied*. As illustrations, we refer to the modes already enumerated, in which the application of the chemical preparation in the shape of a *solid chalk*, of *fluid ink*, and of *pure oil*, directly applied to the stone, have been pointed out, and the effects arising from each explained. It is the grease therefore which prints, and the lampblack introduced into the lithographic materials is of no other use than to enable the artist to judge of the quantity of grease imparted to the stone. That it does not in the slightest degree contribute to produce greater darkness in the impression, is proved by a very curious phenomenon. The design may be (and often is, in the progress of printing) washed out with turpentine, so as to become quite invisible; and a looker-on, unacquainted with the subject, would suppose the work to be completely destroyed; but it is the *black* only

which has disappeared; the *grease* remains, and on being rolled in again, the drawing re-appears uninjured.

The variation in the quality of the tints, arising from the mode in which the grease is applied, may be further illustrated by reference to the *dabber*, which is an instrument by which tints of exceeding delicacy may be produced. It is made of very smooth leather, being somewhat round on its face, and stuffed with cotton wool. On the face of the dabber a lithographic preparation, softer than the chalk, is evenly and thinly applied with a hard brush, and afterwards imparted to the stone by repeated blows with the instrument. The dabber was formerly much in use, particularly for delicate skies; but as lithography has been longer cultivated among us, our artists have acquired greater manual dexterity, and produce tints of the greatest delicacy with the hand alone, which have the recommendation of standing better than those produced with the dabber. Another mode of applying the greasy material, which was introduced some years back, and was found in skilful hands to produce very effective results, was by means of a stump, as in crayon drawing [CRAYONS], to which the process is very similar. Again, with a modification of the ink already described, drawings were made by washing, or laying in tints, with brushes (or camel-hair pencils) much as drawings are ordinarily made with India-ink or sepia. By both these means almost perfect fac-similes of artists' sketches may be produced: indeed, as is evident, lithography admits of any mode of manipulation which may suit the habits, taste, or style of the artist, so that it be consistent with the main principle of the art.

The printing from two or more stones, which was practised with indifferent success almost in the earliest stages of lithography by Senefelder and others, has within the last few years been very extensively practised. In this style, when all that is desired is to imitate a drawing made on tinted paper, with the high lights laid on with white, the drawing is first made in the usual way, with chalk on a grained stone, but more slight, the sky and other delicate tints being omitted, and these are superadded from the "*tint stone*." The tint is executed with facility by the printer on another stone (polished), with a modified preparation of chemical ink, and thus much labour is saved to the artist. The extreme lights are then scraped out on this tint stone, and the printer superadds the impressions from it to those already taken from the drawing on the other stone; of course taking great care that the two fit well, or "*register*," as it is technically called.

But the most important application of this process is in the production of copies of coloured drawings and paintings; a process known as *chromo-lithography*. The object here being to produce as nearly as possible fac-similes in colour, touch, and texture, as well as in drawing and light and shadow, of pictures from the pencils of painters of the highest standing, it has been found necessary to employ a large number of stones, in order to produce the almost infinite varieties of tints which are found united in a single picture; every stone giving a separate impression in its own particular colour or tint. The mode of procedure is somewhat as follows. First, an outline of the entire subject is made by means of transfer paper, or otherwise, on a stone which is called the outline or key-stone of the work. This stone yields impressions which are transferred as guides to all the other stones. On a second and third stone which serve as the basis of the print the general effect of the drawing is washed in, and from these are printed what may be called the *chiaroscuro*, in a faint tint of sepia and of a neutral-colour or gray: corresponding in fact very nearly to the neutral or dead-colouring of a water-colour drawing in the method adopted by the early water-colour painters. The stones which follow are each charged with a particular colour or tint, and each leaves its impression on only a particular portion of the print: one stone printing only the parts which are intended to be yellow or a modification of yellow; another red, another blue, and so on. Other stones charged in parts with grays or secondary colours serve to blend and harmonise the crude colours; others follow which modify these, and finally, one gives the sharp dark touches, and is usually followed by another which supplies a sort of glaze or finishing wash, and subdues and harmonises the whole. Of course, we have only broadly indicated the general method. It will be understood that the sequence of the colours in the printing; the special quality and strength to be given to each particular tint; the effect to be produced by their superposition, and many other particulars, have all to be taken into account in planning the arrangement of the colours on the stones; since a sequence in some respects different, and an entirely different modification of colours, have to be employed for the works of most artists; and it happens that much of the colour on each of the earlier stones is covered by that of succeeding stones, and that thus only can the broken tints of the original be imitated. It is in fact only by watching the progress of a print through all its stages that any clear idea can be obtained of the beauty and accuracy of the whole process, of the prevision that must be exercised, and of the skill, care, and taste required at every step to carry it to a successful termination. For some of the more elaborate prints—one or two after Turner, for instance—from thirty to forty stones have been required to produce a finished print. And in order to produce this print, it must be borne in mind that each sheet of paper has to be passed as many times through the press as there are stones, since each stone imprints upon it only its own particular section of the work. Of course, in proportion to the increase in the number of the

stones, does the difficulty increase of making the work upon each fall exactly upon its proper place in the general design; for if any one were misplaced only the fiftieth of an inch, the drawing and colour of the whole would be disturbed. Hence it is found necessary to arrange the register, or adjustment of the stones, with the utmost care and precision; and to exercise the most careful supervision in the printing (which is entirely a hand process), since the sheet of paper expands considerably in passing through the press, and has to be dried and re-damped before it can be passed through again. But practically this is all accomplished with seeming ease, and a large and most complex subject will be found, when the last stage has been reached, to bear the most minute scrutiny; and the result, even when the copy is placed alongside the original, will surprise and delight equally those who have followed the work through its several steps, and those who may only examine the completed work.

Transfer lithography has been applied in other ways than the one already explained: indeed it would be difficult to fix limits to its capabilities, improvable as they may be in the hands of able chemists. Among the transfer modes, that of *printing copper-plate engravings from stone* is worthy of notice. An impression is taken on unsized paper from the copper-plate, and without delay transferred, by passing through a press, to a polished stone; it is then acidulated, and the printing proceeds in the usual way. In some kind of work the impressions thus obtained are scarcely distinguishable from those printed direct from the copper. The advantage which this application of lithography holds out is most apparent where economy or great despatch are important. These objects are both obtained by transferring impressions to several stones, or several impressions to one stone if the design be small, when the numbers can be multiplied with great rapidity, and without the original engraving being at all worn.

Plates of zinc are for some purposes much used as substitutes for the German stones, in chemical printing, and the practice is then called *Zincography*; but excepting the difference of the material on which the work is performed, it is precisely the same art as lithography. Zinc plates have the advantages of greater portability, and of being less liable to break from the pressure in printing.

LITHONTRIPTICS, termed also **LITHONTHRYPTICS**, or **ANTILITHICS** (*λίθος*, a stone, and *τρίβω*, to rub or bruise), medicines or other means which are thought to possess the power of dissolving stone or calculus in the urinary organs. The calculous concretions which are apt to form in the kidneys or bladder are of very different kinds, originating in different constitutions or in different habits of life or locality of abode. They are also different, not only according to the time of life when their formation began, but they often become varied in the progress of their increase, and are different in the strata of which they are composed.

It requires, therefore, not only very close investigation into the characters of the urine of a person supposed to be affected with calculous concretion, but also no slight acquaintance with the chemistry and physiology of that fluid, and the great influence of the nature of the food and drink on its composition, to be able to direct the use of medicines which are regarded as lithontriptic. With few exceptions, their employment has been nearly empirical; and aggravation of the case has as frequently resulted as benefit from their employment. The researches of recent chemists and pathologists have given something approaching to a scientific explanation of the circumstances under which calculi form, as well as of their varied characters; so that more good may reasonably be expected from the use of lithontriptics than has hitherto been realised. [CALCULUS.]

Of the twelve or thirteen varieties of calculus concretions which have been discovered in the bladder or kidneys of the human subject, some are of very rare occurrence, while the more common ones may be classed under two distinct heads—those which form under the prevalence of the uric or lithic acid state of constitution, and those which form under the prevalence of the phosphatic state of constitution. These sometimes alternate, and indeed the concretions which belong to the last class have almost invariably a nucleus or centre of the first kind, which shows how very important it is to avoid the causes of the lithic acid formations.

Independent of constitutional peculiarities, the leading causes of the formation of calculous concretions are errors in diet or regimen. The kidney is the great channel for the expulsion from the system of the azotised or nitrogenous principles of the blood, as well as of many saline particles, which were once an integral part of the body, but now effete; and to keep these in suspension, so as to ensure their elimination from the body, a due quantity of an aqueous menstruum is required. Hence whatever reduces the quantity of urine below the proper standard predisposes to the formation of calculi. Now an excess of animal food, particularly if exercise be neglected, and strong wines—in a word, rich living, with indolent habits—are the frequent origin of calculous complaints. Crude vegetables, with bad clothing and exposure to cold and damp, which interfere with the healthy action of the skin, equally predisposes to the formation of stone, and thus the poor suffer from it as well as the wealthy. The causes being so widely different, the mode of treatment must also be different. A specific cannot therefore exist, and all unskilful tampering with a case must lead to most hurtful results. Medicines taken by the mouth (and such alone can be used where the stone is in the kidney) have

been hitherto more successful in relieving the distressing symptoms than solvents thrown into the bladder. There is, however, ground for believing that in certain cases, under competent direction, chemical agents and perhaps galvanism may be made available to dissolve the concretions in the bladder. These agents are quite distinct from any mechanical means for crushing the stone.

(See Brodie, *Lectures on Diseases of the Urinary Organs*, 2nd ed.; and particularly the very excellent work of Dr. Willis, *Urinary Diseases and their Treatment*, 1838.)

LITHOTOMY (from *λίθος*, a stone, and *τέμνω*, to cut). Although urinary calculi may be extracted from the kidneys, urethra, or bladder, the term lithotomy is restricted to the operation of cutting into this latter viscus for the purpose of removing one or more stones. From the complex nature of the fluid secreted by the kidneys, and the quantity of saline matters which it holds in solution, deposits not unfrequently take place in one or other of the cavities to which the urine has access. Hence solid concretions, or urinary calculi, may be met with in the kidneys, ureters, bladder, or urethra; but the majority of these concretions are believed to be formed originally in the kidneys. Now, if we suppose one of these calculi to have descended into the bladder, it is easy to imagine that it would there form a nucleus, around which the addition of fresh matter would be constantly adding to its bulk: *a priori* reasoning would lead us to suppose such to be the result, and that this actually takes place is proved by the fact that many calculi have for their nucleus foreign bodies that have accidentally entered the bladder, as bullets, splinters of bone, bits of bougie, &c. The number and size of calculi met with in the bladder differ as much as their form and composition vary, and their magnitude is generally in an inverse ratio to their number. A case has been recorded in which 398 calculi, from the size of a pea to that of an olive, were found in the bladder after death; while, in a case described by the late Sir James Earle, a stone was extracted after death which weighed 44 ounces, its long axis measuring 16 inches, and the shorter 14; but the average size of vesical calculi is about that of a walnut. Their form is mostly spheroidal, or egg-shaped, and sometimes flattened on two sides like an almond. [CALCULUS.]

According to their composition, they are either soft and friable, or very dense and hard, and their surface may be quite smooth or beset with numerous tubercles. These circumstances, together with their loose or fixed position in the bladder, have considerable influence in determining the comparative severity of the symptoms. Children and aged persons are more subject to the disease than those in the vigour of life, and males than females; the inhabitants of temperate climates than those of higher or lower latitudes.

Symptoms of Stone in the Bladder.—These consist in a troublesome itching, sometimes amounting to pain, at the extremity of the penis, with a frequent desire to make water and evacuate the bowels; the urine is voided with great pain, particularly the last drops, and while flowing in a full stream is liable to be suddenly arrested, from the stone falling against the vesical orifice of the urethra. When much irritation is present, the urine on cooling becomes cloudy, and deposits a large quantity of ropy mucus, not unfrequently mixed with blood, especially after any rough exercise. All these symptoms vary in degree, according to the size of the stone and the smoothness or roughness of its surface, its fixed or loose position in the bladder, the quality of the urine, and the condition of the bladder. Instances are recorded of persons living with stone in the bladder for years, yet suffering little or no inconvenience from it; but these cases must be considered exceptions. In general the health sooner or later gives way, and, without recourse to one of the operations we are about to speak of, the patient lingers out a miserable existence till death terminates his sufferings. Nearly all the symptoms we have just described as belonging to stone in the bladder may however be simulated by other diseases of the bladder or neighbouring parts; a positive diagnosis, therefore, can never be made before *sounding* the patient. This consists in introducing into the bladder, through the urethra, a metallic instrument called a sound, by means of which the stone can be plainly felt, and an audible noise perceived on striking it: till this be rendered evident no surgeon would be justified in undertaking the operation. It sometimes happens that stones are forced, by the violent contractions of the bladder during fits of the complaint, between the fasciculi of the muscular coat of this viscus, so as to become what is termed encysted; or they may become adherent to some portion of the parietes of the bladder: under these circumstances the surgeon would hesitate before he undertook the operation.

Modes of performing Lithotomy.—To describe at length the various modes of operating for the stone, and the modifications which each method has undergone, would occupy too much space in a publication not strictly surgical; we shall therefore merely glance cursorily at those formerly in use, while we direct our attention more particularly to the method which is employed at the present day.

Of the Apparatus Minor, Cutting on the Gripe, or Celsus's Method.—This is the most ancient kind of lithotomy, and has probably been practised from time immemorial; but Celsus having first described it, it has been called *Lithotomia Celsiana*; and from the stone, previously fixed by the pressure of the fingers in the anus, being cut directly upon, *cutting on the gripe*, a knife and a hook being the only instruments used. The appellation of the *lesser apparatus* was given to it by

Marianus, in order to distinguish it from a method which he described, called the *apparatus major*, from the many instruments employed. The objections to cutting on the gripe are,—1st, it is only applicable to children under fourteen years of age; 2nd, it is uncertain what parts are divided, this depending on the degree of force employed in making the stone project in the perineum; 3rd, the injury liable to be inflicted on parts whose integrity is essential to the success of the operation.

Apparatus Major, or *Marian Method*, was founded on erroneous principles, and in ignorance of the nature of the parts to be operated on. It was supposed that wounds of membranous parts would not heal, while their dilatation might be undertaken with impunity. In conformity with these notions, the precept of Celsus, "*Ut plaga paulo major quam calculus sit*," was neglected, and the object endeavoured to be attained was, to do as little as possible with the knife, and as much as possible with instruments called dilators; but the parts thus subjected to attempts at dilatation are inelastic, and consequently were lacerated. The severe injury thus produced rendered this one of the most fatal operations in surgery; but notwithstanding this, it was practised for near 200 years, till Frère Jacques, in 1697, taught at Paris the method at present in use.

High Operation, so named from the incision into the bladder being made above the pubes, was first practised at Paris in 1475, by Colot, as an experiment on a criminal, by permission of Louis XI.; but the earliest published account of this mode of operating was in 1556, by Pierre Franco. This method is most applicable to those cases in which the stone is too large to be extracted from the perineum, or where there is disease of the urethra and prostate gland; but there are several objections to it, and it is now entirely abandoned.

Operation through the Rectum.—This method was first suggested in a work published in the 16th century; but the proposal never received much attention till the year 1816, when it was revived by M. Sanson, of Paris, and carried into operation by him and by Dupuytren; but the unfavourable results which attended the performance of this operation prevented its being generally tried or adopted, and no one of the present day ever thinks of performing it.

Lateral Operation,—so called from the prostate gland and neck of the bladder being cut laterally, in order to avoid wounding the rectum, is that adopted at the present day. It was first practised by Pierre Franco, a surgeon at Tourrières, but he never established the method as a permanent improvement in surgery; this was left for Frère Jacques, a priest, who in 1697 came to Paris in order to make known this method, which he employed with great success at various places. Although it appears that he was not quite so successful as he had led the world to believe, the superiority of his mode of operating was immediately perceived and recognised, and, with slight modifications, was adopted by most of the surgeons of that period. Hitherto the Marian section had been used: the advantages of an operation by which a free opening was made into the bladder, over one in which it was so small as not to admit of the extraction of the stone without laceration of the parts are too obvious to require comment. Surgeons of the present day differ somewhat as to the extent of the opening to be made into the bladder, and on the choice of instruments to be employed: some make use of a common scalpel, which cuts into the bladder from without inwards; while others prefer the bistoure caché, or gorget, which divides the prostate gland and neck of the bladder from within outwards. Having premised thus far, we will proceed to describe the operation as usually undertaken with the cutting gorget. The patient having been sounded, to ascertain that the stone is actually within the bladder (for instances have occurred of stone becoming encysted a short period before the operation), and the rectum being emptied by means of a clyster, he is placed on his back upon a table, with his buttocks projecting rather beyond its edge; he should be directed to grasp the outside of each foot with the hand of the same side, and the two pair should then be firmly bound together. A staff, which is an instrument shaped very much like a catheter, or sound, but somewhat longer, and grooved on its convex side, is passed through the urethra into the bladder, where it must be retained firmly by an assistant; its convexity looking towards the perineum, and the groove slightly inclined to the left side of the patient. The operator now commences his incision below the bulb of the urethra, about an inch and a quarter in front of the anus, and continues it obliquely downwards to the left of the raphe of the perineum for three inches, till it reaches midway between the tuberosity of the ischium and the anus: this should cut through the integuments and superficial fascia. The next incision, made in the same direction, divides the transversus perinei muscle, and exposes the membranous portion of the urethra, which must be opened, and the groove in the staff felt for with the finger; into this groove, which serves as a director for making the concluding section of the operation, is inserted the beak of the *gorget* (a sort of knife terminated by a beak, that fits into the groove of the staff). The operator now rises from his chair, and, taking the staff in his left hand, raises its handle from the abdomen till it forms nearly a right angle with the patient's body; the gorget is now pushed onwards, along the groove, till it enters the bladder. By raising the handle of the staff the gorget is made to enter the bladder in a direction corresponding with its axis, and the danger of wounding the rectum is thereby avoided. As soon as the gorget has been introduced the staff

is withdrawn, and a pair of long forceps, expressly adapted for this operation, is passed along the gorget into the bladder, and this latter instrument withdrawn. The stone is now to be seized, and gently extracted; but it sometimes happens that a stone is too large to be removed without using a degree of force that would be perfectly unjustifiable: in this case, if the wound will not admit of further enlargement, nothing remains to be done but crushing it, and thus taking it away piecemeal. A stone should always be examined immediately after it is extracted, because its appearance conveys some information concerning the existence of others; and in every instance the cavity of the bladder should be explored with the finger, to ascertain that there is no other stone present. Encysted calculi seldom require an operation for their removal, but should this be necessary, the cyst may be opened by a blunt-pointed bistoury, and the stone taken away. When a stone is known to be of ample size, some operators perform what is called the bilateral operation, from both sides of the prostate gland being cut; for this purpose a double-edged knife has been invented, called the *double lithotome*.

Lithotomy in Women.—From the shortness, largeness, and very dilatable nature of the female urethra, the surgeon is seldom called upon to perform the operation in women. The formation of calculi is perhaps not less common in women than in men; but from the anatomical circumstances just alluded to, stones of considerable magnitude have been voided spontaneously. This fact has suggested the plan of mechanically dilating the urethra, and thus extracting them without the employment of any cutting instruments; but where the stone is very large, the degree of dilatation necessary for its extraction is liable to produce paralysis of the part, and incontinence of urine ever after. To avoid these evils, an artificial opening should be made into the bladder. The operation is simple: a straight staff, or director, is introduced through the meatus urinarius; the groove is turned obliquely downwards and outwards, in a direction parallel to the ramus of the left os pubis; and the knife is thus conducted into the bladder, and makes the necessary incision through the whole extent of the passage and neck of the bladder.

Treatment after the Operation.—The dangers to be guarded against after an operation of lithotomy are, inflammation of the bladder and peritoneum; infiltration of urine into the cellular texture of the perineum and parts adjacent; and hæmorrhage. To prevent the dangers that would arise from inflammation, the patient should be kept perfectly quiet, and on a low regimen; but supposing it to have set in, the most prompt and energetic measures must be had recourse to; venesection, the use of the warm bath and fomentations, with the administration of such medicines as are known to be most efficacious in such cases, afford the only chance of preserving the patient. Infiltration is to be avoided by placing the patient in such a position that the urine can flow readily from the wound, which should be left uncovered, or this end is attained more effectually by introducing an elastic gum catheter into the bladder, and suffering it to remain there for the first two or three days. Hæmorrhage is fortunately a rare occurrence, but should this take place, pressure, made by means of sponge or lint compresses, may be tried; and if this fail, the bleeding vessel must be sought for and tied.

LITHOTRITY (from λίθος, a stone, and the root τρι, to pierce); *Lithotripsy* (from λίθος, and τρίζω, to break), "the reduction of a calculus in the bladder into small pieces, by means of instruments passed into that organ through the urethra, so that the fragments may be discharged through the latter tube, and no necessity remain for the performance of lithotomy." This operation, which must be ranked among the most brilliant achievements of modern surgery, was first seriously proposed in 1812, and Gruithuisen, a Bavarian surgeon, constructed an apparatus for performing it. But the originality of the idea was probably derived from ancient writers, several of whom speak of the practicability of breaking stones within the bladder, although they make no mention of the mode of performing it. At the commencement of the 19th century, Rodriguez, a physician of Malaga, is said to have broken a stone in the bladder by striking it with a catheter; but the first suggestion we meet with of an apparatus constructed expressly for this purpose is by Gruithuisen. It consisted of a wide straight tube, which was introduced through the urethra into the bladder. Through the tube was passed a noose of copper wire (by which the stone was caught hold of and fixed) and a rod terminating in a circle of teeth or a spear-point; a drilling-motion was now given to the latter instrument by means of a bow, and the stone was thus perforated or broken. Since this period, the operation has undergone successive improvements in the hands of Leroy, Civiale, and Heurteloup. The following is the mode of proceeding adopted by this last gentleman. The patient is placed on an operating bed, so constructed as to admit of any inclination being given to it that the operator may think proper. At its foot is an apparatus for affording a fulcrum to the instrument which is to be passed into the bladder; and two slippers, securely fixed at a short distance on each side of the apparatus alluded to, serve for securing the feet of the patient, who is placed in a position nearly resembling that chosen for the operation of lithotomy. The bladder is now moderately distended with warm water injected through a catheter. A pair of strong sliding forceps, the opposite surfaces of which are furnished with teeth, are then introduced; and the calculus having been seized, the lower piece of the forceps is fixed to a

vice at the foot of the bed serving as a fulcrum, and the upper piece is struck with a hammer and the calculus broken. Thus, neither the shock arising from the concussion is communicated to the bladder, nor is this organ liable to be injured by the fragments being forcibly projected against its internal surface. The instruments are then withdrawn, and the fragments are afterwards voided with the urine; or if any remain too large to be thus discharged, the operation is repeated from time to time till all is got rid of. It were to be desired that an operation so simple, productive of so little pain, and so entirely free from the dangers attendant on the operation of lithotomy, was more generally applicable than it is found to be, but it is subject to the following disadvantages. The patient does not obtain a cure at once, and in many instances the operation is required to be repeated several times; and as the smallest fragment which remains behind will form the nucleus of a new stone, a recurrence of the disease is more likely to take place after this operation than after lithotomy. It is unfit for calculi formed on extraneous substances which have entered the bladder, for encysted or adherent calculi, for large or very hard calculi, for patients with enlarged prostate gland or diseased bladder, and for children. The accidents liable to arise from the operation are generally less grave than those to which the operation of lithotomy is subject; two of the most serious that have taken place are perforation of the coats of the bladder and the breaking of the instrument within this viscus. But where the stone is small and not too hard, and other favourable circumstances are present, we imagine few could be found who would not give it the preference over the operation of lithotomy.

LITMIC ACID. [LICHENS, COLOURING MATTERS OF.]

LITMUS. [LICHENS, COLOURING MATTERS OF.]

LITMUS, *Medical Uses of*. [ROCHELLA TINCTORIA.]

LITRE, the French standard measure of capacity in the metrical system. It is a cubic decimetre, or a cube whose sides are each 3.9371 English inches. It contains 61.0280 English cubic inches, for four litres and a half make, roughly speaking, an imperial GALLON. The litre is therefore a little less than our quart: more precisely, it is .22009687 of a gallon.

LITURGY (from the Greek *λειτουργία*, which originally signified at Athens "certain public functions or duties to which the citizens were personally liable") is a form of public devotion, and more particularly the Office of Common Prayer used in our own church. In the Greek or Constantinopolitan church three Liturgies are in use, those of Basil, Chrysostom, and the Liturgy of the Præsanctified. In the Romish church the Liturgy is divided into several books or offices, as the breviary, the ceremoniale, or office peculiar to the pope; the missal, or office of the mass; the pontificale, directing the functions of the bishops; and the rituale, or pastorale, for the guidance of the simple priests. The Spanish is better known by the name of the Mozarabic Liturgy. The Ambrosian Liturgy is that more particularly in use in the church of Milan. In France the church of St. Martin at Tours had a breviary of its own, which was neither the Roman nor that of Tours; and the same difference obtained at St. Quintin and in other Gallican churches.

At the Reformation all the Protestant churches on the continent, without a single exception, introduced Liturgies for the more uniform celebration of divine service.

Previous to the Reformation of the Church of England the service was performed in Latin, and different Liturgies were used with us, also, in different parts of the kingdom. The cathedrals of York, Lincoln, Hereford, and Bangor, and even Aberdeen in Scotland, had their respective uses; but no cathedral had such a variety of service books for its use as Sarum. "Use" was another name for the Ordinale, or complete service of the church of Salisbury, instituted by bishop Osmund in 1077. It was also named the Consuetudinary; and in Knighton's and Higden's time it obtained almost all over England, Wales, and Ireland. The whole province of Canterbury adopted it, and in right of it the bishop of Salisbury was precentor in the college of bishops whenever the archbishop of Canterbury performed divine service. (Lyndwood, 'Provenc. de feriis' c. ult.)

The publication of king Henry the Eighth's 'Primer' in 1535, in the vernacular tongue, was one of the first steps in the reformation of doctrine and worship in the Church of England. It was followed in 1537 by 'The Godly and Pious Institution of a Christian Man,' containing a declaration of the Lord's Prayer, the Ave Maria, the Creed, the Ten Commandments, the Seven Sacraments, &c., republished with corrections and alterations in 1540 and 1543. In 1545 a second 'Primer' came out; and in 1547, 1st Edward VI., archbishop Cranmer, bishop Ridley, with eleven other bishops and eminent divines, were commissioned by the king in council to compile a Liturgy in the English language free from the erroneous doctrines by which the Latin Liturgies of the church, while unreformed, had been distinguished. This was confirmed by parliament in 1548, and published in 1549. In 1551 it was slightly revised, and again confirmed in parliament; but both this and the former act of 1548 were repealed on the 1st of Mary, as not agreeable to the principles of the Romish Church, which she was about to restore. Upon the accession of Elizabeth the act of repeal was reversed; several learned divines, headed by archbishop Parker, were appointed to make another review of King Edward's Liturgies, when the restoration of the second book of King Edward VI. was determined upon, and finally confirmed by parliament. The Act

received the royal assent April 29th, 1559. In the 1st of James I., after the conference at Hampton Court between that prince with Archbishop Whitgift and other bishops and divines on one side, and Dr. Reynolds, with some other puritans on the other, a few slight alterations were introduced, the chief of which consisted in adding some forms of Thanksgiving at the end of the Litany, and an addition to the Catechism concerning the sacraments; and in the rubric in the beginning of the office for private baptism the words "lawful minister" were inserted to prevent midwives or laymen from presuming to baptise. Charles I. made some slight alterations also, by his sole authority. Under the Commonwealth the use of the Liturgy was generally discontinued. Charles II., in 1661, issued a commission to empower twelve bishops and as many Presbyterian divines to consider of the objections raised against the Liturgy, and to make such reasonable and necessary alterations as they should jointly agree upon; nine assistants on each side being added to supply the place of any of the twelve principals who should happen to be absent. On the episcopal side were Dr. Fruen, archbishop of York, Dr. Sheldon, bishop of London, Dr. Cosin, bishop of Durham, Dr. Warner, bishop of Chichester, Dr. Hinchman, bishop of Salisbury, Dr. Morley, bishop of Worcester, Dr. Sanderson, bishop of Lincoln, Dr. Laney, bishop of Peterborough, Dr. Walton, bishop of Chester, Dr. Stern, bishop of Carlisle, and Dr. Gauden, bishop of Exeter. On the Presbyterian side were Dr. Reynolds, bishop of Norwich, Dr. Tuckney, Dr. Conant, Dr. Spurstow, Dr. Wallis, Dr. Manton, Mr. Calamy, Mr. Baxter, Mr. Jackson, Mr. Case, Mr. Clark, Mr. Newcomen. The coadjutors on the Episcopal side were Dr. Earles, dean of Westminster, Dr. Heylin, Dr. Hackett, Dr. Barwick, Dr. Gunning, Dr. Pearson, Dr. Pierce, Dr. Sparrow, and Mr. Thorndike. Those on the Presbyterian side, Dr. Horton, Dr. Jacob, Mr. Bates, Mr. Rawlinson, Mr. Cooper, Dr. Lightfoot, Dr. Collins, Dr. Woodbridge, Mr. Drake. These commissioners held several meetings at the Savoy, but to little purpose. The king's commission gave them no further power than to "compare the Common-Prayer Book with the most ancient Liturgies that had been used in the church in the most primitive and purest times;" and required them "to avoid as much as possible all unnecessary alterations of the forms and Liturgy wherewith the people were altogether acquainted, and had so long received in the Church of England." The Presbyterians, however, would not allow that the Liturgy was capable of amendment, and Baxter had prepared and offered one of his own to be substituted in its room. The Conference at length broke up without anything being done, except that some particular alterations were proposed by the Episcopal divines, which in the May following were considered and agreed to by the whole clergy in convocation. The principal of them were, that several lessons in the Calendar were changed for others more proper for the days; the prayers for particular occasions were disjoined from the Liturgy, and the two prayers to be used in the Ember-week, the prayer for the parliament, that for all conditions of men, and the general Thanksgiving were added; several of the Collects were altered; the Epistles and Gospels were taken out of the last translation of the Bible, being read before according to the old translation; but the older version of the Psalms was retained; the office for baptism of those of riper years, and the Forms of Prayer to be used at sea, were added. In a word, the whole Liturgy was then brought to that state in which it now stands; and was unanimously subscribed by both houses of convocation of both provinces on Friday, 20th of December, 1661; and being brought to the House of Lords the March following, both Houses passed an Act for its establishment; the Earl of Clarendon, then lord chancellor, was ordered to return the thanks of the lords to the bishops and clergy of both provinces for the great care and industry shown in the review of it; and it received the king's assent on May 19, 1662.

Among what are called the Additional Manuscripts in the British Museum is 'An Apparatus of Materials,' in forty-five volumes, being a collection of notes and observations on the Liturgy, and various other subjects connected with the offices of the church, by a clergyman of the Church of England, who directed them to be deposited in that institution, but that his name should remain unknown. These volumes were deposited in the British Museum in 1791.

Within the last few years several attempts have been made, but hitherto successfully opposed by the heads of the church, to obtain a revision of the Liturgy, the objections stated to it being that it is too long, and has too many repetitions, for one service, to which others add that particular parts require alteration or modification.

LITUUS, a name given to a spiral thus described:—Let a variable circular sector always have its centre at one fixed point, and one of its terminal radii in a given direction. Let the area of the sector always remain the same; then the extremity of the other terminal radius describes the lituus. The polar equation of this spiral is $r^2\theta = a$.

LITUUS, a crooked staff resembling a crozier, used by the augurs among the ancient Romans in making their observations on the heavens, hence called the *Augural lituus*. Dr. E. D. Clarke asserts that there was an older lituus, called the *Regal* or *Quirinal lituus*, which the ancient kings of Italy held as a sceptre in their hands long before the time of Romulus or the institution of the Augurate, particularly mentioned by Donatus and Servius in their Commentaries upon Virgil.

The lituus is often represented on Etruscan and Roman works of art. A sort of horn or trumpet, the end of which was curved, and which emitted a sharp shrill sound, was also called a lituus. It was used for

sacerdotal purposes, and in the army. The etymology of the name is uncertain; but it is believed that the word was borrowed from the Etruscans, as there is little doubt that the augur's lituus itself was.

LIVE STOCK. The animals necessary for the stocking and cultivation of a farm, and those which are kept on it for profit, or for the sake of their dung, are called the live stock of the farm, in contradistinction to the dead stock, which consists of the implements of husbandry and the produce stored up for use.

The live stock on a farm must vary according to circumstances. The number of horses or oxen kept for the cultivation of the land and other farming operations should be exactly proportioned to the work to be done. If they are too few, none of the operations will be performed in their proper time, and the crops will suffer in consequence. If there are too many, the surplus beyond what is strictly required is maintained out of the profits of the farm. To have the exact number of animals which will give the greatest profit is one of the most important problems which a farmer has to solve: what may be very profitable in one case may be the reverse in another; and, as a general maxim, it may be laid down, that the fewer mouths he has to feed, unless they produce an evident profit, the less loss he is likely to incur. But this rule admits of many exceptions. It is of great importance, in taking a farm, to calculate the extent of the arable land, so that it can be properly cultivated by a certain number of pairs of horses. It is an old measure of land to divide it into so many ploughs, that is, so many portions which can be tilled with one plough each. When there are several of these, it is useful to have an odd horse over the usual number required for two or three ploughs, to relieve the others occasionally. The work is thus done more regularly and with greater ease. Where there are two ploughs with two horses each, a fifth horse should be kept, and so in proportion for a greater number. The odd horse will always be found extremely useful, if not indispensable, and the expense of his keep will be amply repaid by the regularity and ease with which the whole work of the farm will be done, and the relief which occasional rest will give to the other horses.

The other part of the live stock kept on a farm must depend on various circumstances. Where there is good grazing land, the profit on the improvement of the live stock, or their produce, is evident and easily ascertained. But where animals are kept upon artificial food or fatted in stalls, it is often a difficult question to answer, whether there is a profit on their keep or not. In most cases, the manure which their dung and litter afford being considered, there is no loss. If manure could be obtained in sufficient quantities to recruit the land, at a reasonable price, it might often be more advantageous to sell off all the hay and straw of a farm, and to keep only the cattle necessary to till the ground or supply the farmer's family. But this can only be the case in the immediate neighbourhood of large towns. In the country at a greater distance, manure must be produced on the farm; and for this purpose live stock must be kept. The management and feeding of live stock is therefore an important part of husbandry, and more skill has been displayed in the selection of profitable stock than in the improvement of tillage. Some men have made great profits by improving the breed of cattle and sheep, by selecting the animals which will fatten most readily, and by feeding them economically. It requires much experience to ascertain what stock is most profitable on different kinds of land and in various situations. Unless very minute accounts be kept, the result can never be exactly known. It is not always the beast which brings most money in the market that has been most profitable; and many an animal which has been praised and admired has caused a heavy loss to the feeder. Unless a man breeds the animals which are to be fatted, he must frequently buy and sell; and an accurate knowledge of the qualities of live stock and their value, both lean and fat, is indispensable. However honest may be the salesman he may employ, he cannot expect him to feel the same interest in a purchase or sale, for which he is paid his commission, as the person whose profit or loss depends on a judicious selection and a good bargain. Every farmer therefore should endeavour to acquire a thorough knowledge of stock, and carefully attend all markets within his reach to watch the fluctuation in the prices. It will generally be found that the principal profit in feeding stock is the manure, and to this the greatest attention should be directed. A little management will often greatly increase both the quantity and quality of this indispensable substance, and make all the difference between a loss and a profit in the keeping of stock. [MANURE.]

LIVER, DISEASES OF THE. The liver is subject to all those general morbid changes which, depending on disordered actions of the blood-vessels, modification of the nutritive process, or alterations in the blood itself, may affect most organised parts of the body; such are inflammation (hepatitis), acute and chronic; hypertrophy and atrophy; induration and softening; and the different kind of tumours or transformations of tissue, carcinoma, or cancer, medullary sarcoma, fungus hæmatodes, melanosis, and scrofulous tubercle. It is occasionally infested by parasitic animals (hydatids), which may likewise affect other parts of the body.

But the liver is also liable to other diseases which appertain to it specially, and are connected with its function—secretion. The chemical changes which give rise to the formation of bile in the liver may be so deranged, that one or all of the ingredients of that fluid are increased or diminished in quantity, or vitiated in quality, and such

disorder of the secreting process may manifest itself in several ways: the imperfectly formed fluid passing into the intestines may cause irritation there, and consequently diarrhoea: or being absorbed into the blood, may produce jaundice and its concomitant symptoms; or some of the ingredients of the bile may congregate into solid masses in the ducts of the liver or the gall-bladder, forming gallstones. The diseased state of the liver in which it becomes impregnated with an unnatural quantity of fatty matter may also be reckoned among the diseases appertaining to the special function of the organ, for the bile naturally contains a large proportion of fatty matter (cholesterine); though the chemical composition of this substance, and that of the oil or fat with which the liver is impregnated in disease, appear to be different. [LIVER, in NAT. HIST. DIV.]

Congestion of the Liver.—The complicated structure of the liver renders it possible for various parts of its tissues to become congested. Thus there may be congestion from an increased secretion of bile, and in this case the bile ducts are the parts principally affected. Then the hepatic veins, or the portal veins, may be congested, and this is called *passive congestion*; whilst *active congestion* is said to be present when the arterial capillaries are principally affected. Each of these forms of congestion is attended with peculiar morbid appearances, which have been discovered after death. In these congestions the liver is generally enlarged. In certain states of congestion of the liver, the condition known by the name of *nutmeg liver* is present.

The most frequent cause of hepatic congestion is disease of the heart. When obstruction exists to the circulation, especially on the right side of the heart, the liver is liable to congestion. Such a state is attended with dropsical effusion of the abdomen, and also of the general cellular tissue. Temporary congestion of the liver may be also brought about by sudden chills, the cold stages of fevers, the drinking too largely of alcoholic liquors, injudicious feeding, and exposure to the heat of the sun. In congestion the liver is enlarged externally, there is sallowness of the complexion, the tongue is coated, the bowels constipated, the appetite bad, and there are sickness, vomiting, headache, and general debility. The pulse is slow, compressible, or irregular, or it may be quiet and feeble.

The treatment of congestion of the liver needs not to be very active. Gentle purgatives and diuretics, with rest, and a restricted diet, are generally sufficient.

Acute hepatitis, when it exists in a severe degree, is indicated pretty distinctly not only by the general signs of inflammation and symptomatic fever, such as thirst, heat, and dryness of the skin, increased rapidity of the pulse, &c., but also by local symptoms, which point more especially to the seat of the disease, namely, pain and tenderness on pressure beneath the ribs on the right side, difficult breathing from the liver being pressed upon by the diaphragm when air is drawn into the lungs, and a short dry cough, dependent either on the extension of the inflammation to the diaphragm, or a sympathetic affection of the parts engaged in respiration. The pain in hepatitis so frequently extends to the right shoulder, that pain in that situation has been considered characteristic of disease of the liver. Vomiting is a common attendant on hepatitis, as on inflammation of most of the abdominal viscera. Another symptom is jaundice, which in this case is a consequence of the inflammatory action having disturbed the process by which the components of the bile are formed and separated from the blood.

Inflammation of the liver may terminate in suppuration, and the formation of one or more abscesses, which sometimes attain a very large size in this organ, protrude externally, and even burst and discharge their contents through an opening in the skin.

Acute inflammation may be produced in the liver by any of the influences which give rise to it in other organs; but while the lungs are more subject to this affection in cold climates, the liver is especially liable to it in hot countries.

Chronic hepatitis is indicated by the presence, in a less violent degree, of many of the symptoms which attend the acute disease. Thus, a dull pain or sense of weight in the right side, with some degree of tenderness in the same situation, pain in the right shoulder, slight jaundice or sallowness of the skin, and disorder of the stomach and digestive organs generally, are the most constant signs. It is frequently difficult to distinguish mere chronic inflammation of the liver without enlargement from some disordered states of the stomach and bowels, which sympathise so much with it, and hence has arisen the popular error of designating any chronic disorder of the digestive organs "a liver complaint." We cannot be surprised at this sympathy between the liver, stomach, and bowels, and other viscera of the abdomen in disease, since we know that they are all engaged in one great function—digestion; and are in the healthy state associated together in their action by a natural sympathy for the purpose of co-operation in that function. A structural result of the chronic inflammation of the liver is the deposit of fibrinous matter in its capsular structure, and the production of the diseased state called *cirrhosis*. This is frequently brought on by the abuse of alcoholic beverages, and has got the name of "gin liver."

Increased secretion of bile. The function of the liver is increased by exposure to heat, and there is evidently a relation between the function performed by the lungs and that of the liver. As the former is diminished, the latter is increased. This occurs from exposure to heat,

and is especially seen in the case of Europeans exposed to the heat of tropical climates, or in the hot weather of temperate climates. An increased secretion of bile is attended with an increased action of the bowels, called "bilious diarrhoea." Such increased secretion of bile is attended with congestion, which may terminate in inflammation of the liver, which is attended with a diminution of the biliary secretion.

Various causes may produce a suspension of the processes by which the bile is thrown out of the liver. When this occurs, the bile is absent from the intestinal excretions, and being taken up into the blood produces jaundice. [JAUNDICE.]

The liver is very apt to become enlarged by chronic inflammation, and then can be felt externally. Or such changes may be produced in it by hypertrophy or atrophy of one or more of the tissues composing it, or by the formation of a new tissue, that the passage of the blood through it is impeded, and dropsy of the abdomen (ascites) is the result; this effect however is sometimes a consequence of the chronic inflammation of the liver having extended to the whole lining membrane of the abdominal cavity.

Of the structural diseases, not inflammatory in their nature, some, as scrofulous tubercles, are rarely met with in the liver, others, as carcinoma, are more frequent in it than in most other internal organs, except the intestinal canal. There are no certain means of ascertaining the presence of these diseases in the liver, until the tumours which they form attain such a size as to be felt externally; though it should be suspected, when the general states of the body marking the carcinomatous and tubercular diathesis exist, and still more when these diseases are known to be present in other parts, if at the same time there are marks of irritation and disturbed action of the liver.

The "fatty liver" is a frequent attendant on pulmonary phthisis: it cannot be recognised by any signs during life.

The liver in man, as in many animals, particularly the sheep, is, as we have said, subject to become the seat of parasitic living creatures—hydatids. These are generally contained in great numbers in a firm general cyst, which not uncommonly protrudes externally, and bursts, or is opened by a lancet, when numerous pellucid bladder-like bodies of different sizes, floating in a transparent fluid, escape.

The treatment of diseases of the liver is regulated by the general principles according to which the cure of diseases in other parts is attempted, and will of course vary with the nature of the particular affection requiring it.

LIVER OF ANTIMONY. [ANTIMONY.]

LIVER OF SULPHUR. [POTASSIUM, *Sulphides of.*]

LIVRE, anciently a money of account in France, afterwards a coin. The word is derived from the Roman *libra*, or pound, the standard by which the French money was regulated, twenty sous being made equal to the livre, or libra. Under the decimal system, accounts are now kept in francs of 20 sous, of 10 decimes each, and each decime is divisible into 10 centimes.

The livre was formerly of two kinds, Tournois and Parisis. The *Livre Tournois* contained 20 sous Tournois, and each sol or sous 12 deniers Tournois. The *Livre Parisis* was of 20 sous Parisis, each sous worth 12 deniers Parisis, or 15 deniers Tournois; so that a livre Parisis was equivalent to 25 sous Tournois; the word Parisis being used in opposition to Tournois on account of the rate of money, which was one-fourth higher at Paris than at Tours.

The *Lira Italiana* is the Italian livre, and it varies in value in several states. In Austrian-Lombardy and Piedmont it was worth 8*d.*; in Tuscany 7½*d.*; but the currency has been latterly approximating to the French system, which is now likely to become general.

LIXIVATION, a term employed chiefly in *technical* chemistry to denote the dissolving out of saline matters from an insoluble residue: thus *black ash* is lixivated with water to dissolve out its constituent carbonate of soda, from other insoluble matters consisting chiefly of oxysulphuret of calcium. The solution thus obtained is termed a *lixivium*.

LIXIVIUM. [LIXIVATION.]

LIZARIC ACID. [MADDER, COLOURING MATTERS OF; *Alizarin.*]

LOADSTONE. [MAGNET.]

LOAM, a soil compounded of various earths, of which the chief are silicious sand, clay, and carbonate of lime, or chalk. The other substances which are found in loams, such as iron, magnesia, and various salts, are seldom in such proportions as materially to alter their nature. Decayed vegetable and animal matter, in the form of humus, is found in loams in considerable quantities, and the soil is fertile in proportion.

According as the loams are composed, so they vary in quality. Those which consist of a great portion of loose sand, with little vegetable matter, and with an impregnation of iron, are very unproductive; and those which contain too much clay, and are on an impervious subsoil, are very difficult to cultivate. But between these extremes there are soils which cannot be surpassed in fertility as wheat-land. What renders loams so much more fertile than either clays or sands is, that the pure earths are in themselves almost entirely barren: sand lets the moisture run through it and evaporate rapidly; clay retains it, but locks it up in its own substance, and does not allow the tender young roots of plants to push through it; chalk has the same mechanical quality, besides containing very little organic and soluble matter, from which plants derive their chief increase. Sand and clay

alone, without a considerable portion of organic matter, will not make a rich soil; but when a portion of calcareous earth is joined to both, the vegetable matter is more readily rendered soluble, and the clay and sand are prevented from forming a mortar, which would harden too readily, and prevent the influence of the air from reaching the roots. Good loams allow of that circulation of moisture which acts so prominent a part in the process of vegetation. It is almost universally admitted that the most fertile soils always contain a proportion of calcareous matter; and by adding chalk to those soils in which it does not abound, whether sandy or argillaceous, a manifest improvement is always produced.

It has been asserted that in the climate of France, in the neighbourhood of Paris, the best soil for the growth of wheat is composed of equal portions of fine sand, clay, and chalk. Upon what grounds this is assumed, does not appear very clear. The greater the natural moisture of any climate, the greater proportion of sand is required to make a fertile loam; and the greater the proportion of humus, the less sand will be required to temper the clay. The analysis of soils known to be extremely fertile gives a very great difference in the proportions of the different earths.

In the climate of England the soil which is generally preferred for cultivation is a loam, rather light than heavy; at least half of which is silicious sand, one-third clay, and the rest chalk. Such a soil is called a good loam; it is land which will produce almost every thing which is usually cultivated on sands or clays: it is not too stiff for carrots and turnips, and not too loose for wheat and beans. It is of most easy cultivation at all times of the year, provided the subsoil be sound, and not too retentive of water. It requires only to be occasionally recruited with manure, to restore to it what vegetation has consumed, and to be kept free from the weeds which naturally spring up in all fertile soils. All attempts to improve the nature of a soil should have for their object the bringing it to a state of loam, by the addition of those substances which are deficient. If there is too much clay, chalk and sand may be added, or a portion of the clay may be calcined by burning, in order to destroy its attraction for water, and thus act the part of sand in forming the loam. Limestone or calcareous sand and gravel are still more efficacious for this purpose: they not only correct too great porosity, or too great tenacity, but also act chemically on the organic matter in the soil, rendering it soluble, and fit to be taken up by the roots of plants. If there is too much sand, marl composed of clay and chalk is the remedy. Good loams require much less tillage than stiffer soils, and will bear more stirring to clean them than sands. Hence they are cultivated more economically, and more easily kept free from useless weeds; while the produce is more certain and abundant. They can be impregnated to a higher degree with enriching manures, without danger of root-fallen crops, or of too great an abundance of straw at the expense of the grain. For artificial meadows they are eminently proper: all the grasses grow well in good loams, when they are on a dry or well-drained subsoil, which is an indispensable condition in all good land. Sheep and cattle can be depastured on them during the whole year, except when there is snow on the ground. If there should be means of irrigation, no soil is better suited to it than a light loam on a bed of gravel; or even if the subsoil is clay, provided sufficient under-draining prevent the water from stagnating between the soil and subsoil, which, as practical men very properly express it, would poison any land.

A loamy soil requires less manure to keep it in heart than either clay or sand; for while it is favourable to the process by which organic matter buried deep in the soil is converted into insoluble humus, it also permits that part of it which is nearer to the surface to attract oxygen from the air, and thus it is converted into a soluble extract, which is to the roots of plants what the milk of animals is to their young—a ready-prepared food easily converted into vegetable juices.

The analysis and classification of soils is of the greatest importance to all those who take farms; for the rent of land is very seldom proportioned to its intrinsic value: one farm may be worth double the rent of another, where the apparent difference in the soil is very trifling. Those who have had long experience of the expense of cultivation, and the average produce of certain lands, can nearly guess what rent it may be safe to offer; but a stranger has no criterion to judge by. Hence it is notorious that a stranger coming to take a farm from a distant district is almost invariably deceived. Why should not the value of a soil be ascertained as readily as that of any article of commerce? If there were certain points of comparison, it would be so; but in this the theory of agriculture is woefully deficient. A man guesses at the qualities of land by the colour, the feeling, and other uncertain signs: it seldom or never occurs to a farmer to examine the component parts of a soil, by merely diffusing a portion in water, and testing the deposits—much less to compound artificial soils, and compare them with those found in the fields. Yet every gardener can prepare soils suited to different plants, and make loams of all degrees of richness or consistence. In all these it will be found that sand, clay, chalk, and decayed vegetable substances, in various proportions, are the chief ingredients. If therefore these are found in a natural loam, we may safely conclude that it would be equally productive, and the deficiency of one ingredient may be supplied artificially. This would be going rationally and scientifically to work; and the result would be a more certain and satisfactory practice of husbandry.

LOBELIA INFLATA (Bladder-podded lobelia, or Indian tobacco), *Medical properties of.* This American annual plant possesses in its whole structure some very peculiar properties, approximating to Virginian tobacco so closely as to have received a nearly similar name. The plant flowers in July, and the entire plant or herb is to be taken up in August or September; every part possessing the characteristic properties. These display themselves quickly on those unaccustomed to the use of this herb, even when only a small portion is held in the mouth. "It produces giddiness and pain in the head, with a trembling agitation of the whole body; and at length brings on extreme nausea and vomiting. The taste resembles that of tartar emetic." (Bigelow's 'Medical Botany,' an American Work.) Its secondary effects are great flow of saliva and increased expectoration, with general relaxation of the muscular system, and depression of the heart's action. Small doses are useful in asthma, but in hooping-cough greater relief may be more safely procured by enveloping the chest with flannels steeped in a tepid decoction of poppy heads; renewing these frequently. The seeds are very small, beautifully reticulated, so that they can be easily recognised under the microscope. In cases of an overdose, strong tea, then brandy and ammonia, should be given.

LOBELINE, an oily non-volatile alkaloid found in the Lobelia (*Lobelia inflata*). It is very soluble in water, alcohol, and ether. Administered to animals, it produces narcotic effects.

LOCAL ATTRACTION, a term accepted by men of science as applicable to influences exerted on the compass by substances on ship-board. Few subjects have taxed the patience and intelligence of nautical men so much as that of the disturbance of the compass by local attraction; nor has the consideration of the subject by living philosophers been productive of more than a verification of certain suspected facts.

Professor Airy has indeed deeply investigated the causes as they ordinarily appear, and has been successful in providing some alleviation of the evils attendant upon a disturbed compass; but in other respects nothing of permanent benefit has accrued to the compass question either from committees, or from elaborate experiment; nothing which aids the seaman by an infallible remedy. Were a ship to remain always in nearly the same part of the globe, and her local attraction to remain a constant quantity, Airy's improvements would be all that could be desired; as it is, no other mechanical means of correcting by magnets in a long voyage is so convenient or so manageable.

That the compass was subject to changes and deflections irrespective of terrestrial magnetism, was of little importance in ships constructed only of wood. Irregularities of the compass were occasionally detected, but these were mostly attributable to iron bolts or nails, or accidental deposits of metal, such as a knife or marlinspike upon or near the binnacle. Beyond these casual or accidental disturbances, the mariner of olden time had little to do with local attraction. An iron cargo occasionally caused him some extra watchfulness, but the error once ascertained left him at ease upon the subject of his compass. No sooner however had the interest of merchants increased the space for stowage in their ships, and, in adopting modern improvements, introduced iron knees, chain rigging, and various other metallic appliances, than the consideration of the actual compass course to be steered became involved in new and perplexing corrections, and various speculations concerning a ship's condition as altered by these improvements became the subject of study. For nearly a quarter of a century this state of things was suffered to progress, when the establishment of the present Board of Trade, and the intelligence of its naval heads, introduced a new and still enduring scrutiny.

Ships had begun to be constructed of iron only; some had been built many years previously—for the writer remembers seeing the first iron vessel which ever anchored in the Downs, a fine brig called the 'Tontine,' in about the year 1816. From iron hulls, iron masts and even yards, soon were to be found afloat in British waters. And as if the compass were to be threatened with total rejection, iron ships were soon fitted with steam engines. Wooden steamers had already (about thirty years since) exercised the patience and vigilance of ship masters to a large extent, but changes so enormous were gradually producing a malignant phantom more and more forbidding in its aspect, from its power of eluding the grasp of its pursuers, and deluding them into still deeper swamps of error and disappointment. Such effects then had at first "local attraction." Some, to avert the evils of an invisible and fickle agency, fastened magnets to their decks as palliatives, but they did so with as many misgivings as they still fasten the horse-shoe to the bowsprit end. Any species of "charm" which the credulity of the superstitious could invoke to avert mischief from the compass was eagerly applied to its bowl, or the binnacle, or to the deck, until in 1854, the unfortunate catastrophe of the 'Tayleur,' a fine ship of above 3000 tons (actual measurement) built of iron throughout, and having compartments also of iron, was lost with 290 of her crew at Lambay, on the Irish coast.

The investigation of the causes of her loss resulted in an official report from Captain Walker, (one of the naval heads of the Board of Trade) attributing her destruction to the "supposition" on the part of the Captain, "that the compass before the helmsman was correct," and alleging that the captain "was aware there was a difference of two points between the compasses, but he knew not which was in error."

We see then the effects of compass disturbance, and proceed to

examine the causes, but have to deal with the circumstance of local attraction being liable to sudden and great changes, so that corrections which are available and effective at one period are totally useless at another. It is this change which baffles us, and in it lies the greatest amount of danger to navigation.

Dr. Scoresby, in his patient experiments and indefatigable attention to the subject through many years, has shown that some portion of a ship's local attraction may be traced to her very cradle—that the very hammering and rolling, and bending, and riveting of her plates engenders a mischievous influence variable in its intensity as in its duration, and is thus coexistent with the origin of her frame-work itself. That even the direction of the line of keel while building, as measured by its angle with the magnetic meridian, establishes for a time a systematic derangement of the action of terrestrial forces in which the effects of terrestrial dip and obliquity have their united influence, which may or may not affect the future navigation of the ship by means of a mariner's compass.

Were the efforts of Dr. Scoresby, and Mr. J. R. Napier (the eminent iron ship-builder of Glasgow), and the approach to principles developed by them, not countervailed by the changes incident to every iron ship on leaving her birth-place, little would remain to the sea captain but to receive from the hands of the builder, a diagram of the ship's magnetic condition, as produced by the causes already referred to; and indeed as palpably evident and accurate as her load and light water lines, &c., would be the correcting card so handed over; for it is not difficult to discover a neutral point in every iron ship, at which a standard compass would feel the effects of terrestrial magnetism only. But no sooner, unfortunately, in the process of launching does the ship, if built of metal, plunge into a denser medium, such as water, than the sudden change of temperature affecting the submerged portions of the mass, communicating itself to the upper works, challenges at once the stability of her magnetic condition. Nor is this, at this period, the only enemy to magnetic permanency, for it has been shown by Dr. Scoresby, that the very twist and strain in the framework of the ship consequent upon her being, in launching, raised gradually by the buoyancy of the water, is sufficient to affect materially that which other influences had matured.

The iron ship being once afloat, we shall find still other perplexing disturbances at work, and especially if she be intended for a steamer, with iron masts and yards.

If the latter, the increased hammering in the fitting of the engines adds its quota to the general confusion of conflicting and counteracting forces. The lighting of the fires, the heating of the boilers, the production of steam—each of these is a fertile source of further electric, and therefore magnetic, disturbance. It would seem that the consideration of thermo-electricity, as operating upon the mass of metal in an iron ship, has been somewhat neglected. The enormous change of a single drop of water, which, on its conversion into steam, is expanded into 1700 times its bulk, has been proved years since to generate, or rather to release, a vast amount of electric or magnetic power; and as we cannot circulate electric currents without magnetising iron, when in certain favourable positions with regard to it, the complication of disturbances is so great in an iron steamer that it is not surprising if the wisest heads fail in providing a permanent remedy for local attraction. Ships are "swung" generally at this period, and the question of compass error is supposed by many to have been satisfied if the amount of then existing deviation is recorded. But what follows?

If we test an iron pillar or bar of even a tradesman's shop-front, we shall find that in time, and from its vertical position, it becomes magnetic, and exhibits polarity: and this law affects every vertical bar in the ship. It is an error to suppose that the weight of an iron mass has reference to its magnetic intensity; for, as magnetism seems to collect on surfaces of metal, it follows that a 6-inch hollow iron pipe or funnel, having two surfaces, an inner and an outer, would exhibit more power of disturbing a compass than if it were of solid iron: therefore stove-pipes have been often found dangerous neighbours to a standard or binnacle compass—much more so should we expect an iron mast to be. Hence the very parts used in the construction and fitting of an iron ship are liable to the change to which we have adverted, and this change may be either an increase or diminution of magnetic influence, we know not which; as one piece of iron used in the construction of the ship may and does counteract another, partially or wholly; the change moreover may be either rapid or protracted, until some other new source of disturbance comes into controlling operation.

In process of preparation for sea, cargo of various materials, such as hardware, machinery, or iron bars themselves, loads the ship, increasing the strain upon her plates and knees, &c. With regard to iron bars as a cargo, let any one walk round a heap of bars lying upon a wharf, with a pocket-compass, and remark their effect on the needle (whether lying out of or in the magnetic meridian should be noted). It must be remembered that these are to be placed, we will suppose, in an already magnetised iron ship, and subject, especially in an iron steamer, to another serious source of change, a change in temperature. Now it is known from experiment that the intensity of a magnet is nearly doubled by being raised to a "cherry-heat": the change of temperature in a ship's hold may, even in the tropics, be considered comparatively insignificant, but the fact remains that disturbance of temperature is disturbance of electricity, and as no electric current can circulate

without its attendant magnetism acting at right angles to the direction of such current, it follows that totally unexpected and most intricate and untraceable influences may be set in operation, even by lighting the furnace fires for a few hours in order to take still further precautions in the usual "trial trip" to test both engines and compass. This is another stage at which it is deemed by the majority prudent to finally adjust the "correcting card" for the voyage. This is especially the period of "swinging" her majesty's ships, with what certainty of permanent advantage may be still further illustrated.

We have mentioned her majesty's ships—as an extreme case we now will confine our deductions to the incidents attending their proceeding to sea. It is fair to assume that ships are fitted in still waters, either in harbours or estuaries; whether such ships be new, or have been lying dismantled in ordinary, affects our main scrutiny as to changes in a very immaterial degree. In either case, whatever changes do occur they are due to what Scoresby has called retentive magnetism. Now guns are formed of a metal which, from partial carbonisation, rapid or unequal cooling, and a tendency to crystallisation, or at least a peculiar arrangement of its particles, has in the ordinary form of cast-iron a peculiar aptitude for the absorption of magnetic influence: and, indeed, excellent permanent magnets may be formed of it, inferior only to steel. These guns have moreover to undergo a process of concussion in firing still further calculated to derange local attraction, by increase or diminution, we cannot tell which: and even the training of these guns may, in their altered position, affect the local attraction of the whole ship.

And again, independent of the evolution of magnetism in the boiler, the very act of combustion of coal has its influence on the condition of an iron steamer. For not only does the combination of carbon with the oxygen of the air (which is decomposed in the furnace in the act of combustion) in the form of carbonic acid gas increase the magnetic intensity of the funnel, but the decomposition of the coal itself is a source from which magnetism is as it were poured into the very mass of the ship herself in abundance, perhaps to saturation, if such can exist. In addition to the electro-magnetic disturbance incidental to all decompositions, coal is composed of carbon and "earthy matter." Now pure carbon is of itself capable of polarity, inasmuch as crystallisation is found in the diamond: but the "earthy matter" is worthy of serious examination. Coal varies greatly in the quantity of earthy matter it contains, and for the following reasons: the lower the specific gravity of the coal used, so much the less probability of magnetic disturbance one might look for.

Earthy matter in coal amounts to, in general, from 1 to 10 or 12 per cent., such being either pure oxide of iron, or sulphuret of iron with occasional traces of alumina. Now if we, for experiment, burn off the sulphur by the blowpipe from a small portion of sulphuret of iron, or iron pyrites, we shall find the residue strongly magnetic; and this may be verified by our taking some of the dust of the ash-pit of a furnace, or of a common house-grate, and placing it on a piece of writing-paper; holding a magnet under the paper will at once show polarity in the particles, and moving the magnet along the surface and back again will abundantly show that combustion of coal therefore produces constantly a large number of small distinct magnets, the power of which is increased not only by their being in proximity to each other, but by the high temperature at which they are maintained until usually removed from the ash-pit. When we further consider that in a large steamer some 100 to 200 tons of coal are consumed in a day, it is not too much to say that some tons of magnets are manufactured daily on board these vessels: we say manufactured, for in the form of coal, or even as sulphuret of iron, such is not magnetic.

And again, with all these tendencies to produce a disturbing effect on the known or once ascertained local attraction of the ship, there remains yet the possibility of further inconvenience to the compass arising from heavy pitching or rolling in a sea way: even her "heeling over" is well known to affect the compass to a considerable degree.

Such then is "local attraction" on shipboard; an influence from which no ship nearing the land would be safe, as the changes referred to cannot be anticipated or averted by any process yet known. It remains, therefore, to renew "corrections" as often as possible, using a heavenly body as the sole standard. Under the article COMPASS CORRECTIONS it has already been shown how readily and completely this may be done by means of Saxby's spherograph and Professor Airy's arrangement of soft iron and magnets. Local attraction on shipboard is, therefore, a subject for anxious vigilance on the part of every commander. Many ships are found very unsusceptible of changes; others, after years of inactivity, suddenly become excited. As a general rule, local attraction is expected to diminish after a ship has been a year or two at sea: but no ship or vessel, especially a steamer, ought to be navigated by means of a correcting card, unchecked by frequent celestial observations, for at least the first week or two after leaving port. A prudent commander will never trust to his compass for a single day if azimuths can be taken.

(*Nautical Magazine*; Dr. Scoresby, *Magnetical Investigations*; &c.)

LOCI. [LOCUS.]

LOCK, a fastening in which a moveable bolt may be projected by the action of a key, introduced into the lock in such a manner that the bolt cannot be returned to its original position, so as to release the door or cover, excepting by another application of the key. There are,

however, many locks in which the bolt is projected by the action of a spring, without the aid of the key, and in which it may be drawn back by means of a handle; although it cannot be moved from the other side without the application of the key. In other locks, again, there are two or more bolts, one of which only is under the control of the key, the others being moved by handles; while in another class two or more bolts are shot or projected by the action of the key alone. In addition to such differences, the varieties in the form and size of locks, and in the arrangement of their parts, are almost infinite. In door and closet locks, the bolt is usually projected into a fixed socket. In various kinds of box and cabinet locks the bolt is not projected beyond the casing of the lock, but is caused to shoot into or through a staple which drops into the lock to receive it. In desk-locks and some others the bolts project permanently, and are of a hooked shape, adapted to catch, by a lateral movement, into staples provided to receive them. *Padlocks* are a kind of detached lock in which a curved bar of iron, pivoted to the lock at one end, may be passed through a staple, and then so secured by shooting the bolt into a cavity in its free end, that it cannot be removed from the staples through which it has been passed.

By far the greater number of the contrivances for rendering locks inviolable may be classed under one of three systems of security.

Warded Locks.—The key of an ordinary lock consists of a cylindrical shank with a loop-shaped handle at one end, and a piece called the *bit* projecting from it at or near the other. The bit end of the shank is, in the keys of locks which are to be entered by the key from one side only, made hollow or tubular, to fit on to a pin fixed in the lock; but in locks which may have to be opened from either side, such as ordinary room-door locks, the shank is made solid, and is prolonged beyond the bit, so as to enter the upper part of the key-hole of that plate of the lock which happens to be farthest from the person applying the key. The projecting bit, after being introduced through the key-hole, is turned round within the lock by a rotatory motion imparted, until it comes in contact with a part of the bolt so shaped that the bit cannot pass it, to complete its revolution, without shooting the bolt either backwards or forwards, as the case may be. When thus moved the bolt is retained in its position by a spring, or some other means, until it is again moved by the reverse action of the key.

The first and simplest means by which the entrance of a false key may be rendered difficult, is by giving a peculiar form to the substance of the bit, and either adapting the form of the key-hole exactly to it, or inserting pieces of metal in the lock in such a way as to prevent the admission of a bit of different shape. *Fig. 1* represents several forms

Fig. 1.

of bit commonly used. Of these *a*, *b*, *c*, and *d* are adapted for key-holes of various corresponding forms; while *e* and *f*, though suitable for key-holes of the same general form, admit of further security by forming projections upon the sides of the key-holes.

The next and principal means of security is the use of pieces of metal of various forms, fixed within the lock in such a way that no key can be turned round within it unless corresponding notches are cut in its projecting bit. *Fig. 2*, which represents a portion of the

Fig. 2.

interior of a lock, with the bit end of the key in its place, will illustrate this. Attached to the back-plate are two concentric prominent rings, of different degrees of elevation. These prominent rings are the *wards*, which impede the introduction of a false key. No key could be put into a lock provided with them, unless a notch were made in its bit to correspond with the larger of the two rings; and it is evident that no key could be turned round without having also a notch to correspond with the smaller circle. In the commoner kind of locks the wards seldom form a complete circle, but their effect is the same if they occupy only a small segment. Many wards are of a more complicated character, such as what are termed L, T, or Z wards, from the resemblance of their sectional form to those letters respectively.

The keys must, of course, be cut of a corresponding form, by which the difficulty of imitation is greatly increased.

By referring to the various forms of key represented in *Figs. 3, 4, 5, and 6*, the peculiar advantages and defects of that principle of security which depends on the use of wards, may be readily comprehended. The greatest defect of the system arises from the circumstance that, in ordinary cases, it is not absolutely necessary that a surreptitious instrument should perfectly thread the mazes of the wards. But while the wards afford security against ordinary keys, they afford none whatever against a *pick* or *skeleton key* like *k*, *Fig. 3*, which would open

Fig. 3.

any of the locks suited for *g*, *h*, and *i*, the only part essential to the moving of the bolt being the extremity of the bit, which is retained in the skeleton key with nothing but a slender piece to connect it with the pipe or shank. The security may be greatly increased by the use of other wards, attached to the opposite plate of the lock, and requiring notches in that part of the bit of the key which is represented by the slender connecting piece in the skeleton *k*. Such is the case in all the keys represented in *Figs. 4, 5, and 6*. In *Fig. 4*, *l* represents a key for

Fig. 4.

a solid-warded lock, which might, however, be easily picked by a skeleton key resembling *r*, *Fig. 6*. The greater complication of the wards in *m*, *Fig. 4*, increases the difficulty of picking; while by the adoption of the arrangement shown at *n*, *Fig. 4*, the difficulty of introducing a false key is made perhaps as great as possible, since no instrument that does not thread all the intricacies of the wards could answer the purpose. All the keys hitherto represented, as well as those in *Fig. 6*, are pipe-keys, adapted for such locks as have a fixed pin or axis, and can only be opened from one side. It is, therefore, of no consequence that the wards attached to the back and front plates of the lock should resemble each other. In ordinary door-locks, however, in which the key may have to be inserted from either side, it is essential that the wards attached to the two plates, if such be used, should either be precisely similar, or should bear such a relation to each other that notches may be cut in both sides, or rather edges of the bit, to suit both sets of wards; it being a necessary condition that the two sides of the bit, marked *a* and *b* in the cut, *Fig. 5*, should be perfectly

Fig. 5.

alike. Our remaining illustrations of warded keys are intended to explain the theory of master keys. In *Fig. 6*, the wards of the keys *o*, *p*,

Fig. 6.

and *q* are so far different from each other that neither of those three keys would open the lock designed for either of the other two; but a key formed like *r* would readily open any of the locks of the other three.

One defect of warded locks is that, however complicated they may be, an ingenious picker will mostly be able to detect their form and

position, by inserting a blank key with the bit covered with wax or tallow, so as to receive an impression of the concealed obstructions in the lock. It is a very common practice to cut more notches in the key than there are wards in the lock; so that the complex appearance of a key is no certain proof of the secure construction of the lock to which it belongs. Some contrivance is necessary to keep the bolt steadily in the position in which it is left by the key; and in locks which depend upon wards for their security, this is usually effected by means of a spring, as illustrated by *Fig. 7*, which represents the interior of a small cupboard lock, with the bolt *a d b* half shot, or in a position intermediate between locking and unlocking, and capable of being moved either backwards or forwards by the action of the bit of the key at *c* in a curved hollow formed in the lower edge of the bolt. The necessary raising of the bolt and compression of the spring are properly

Fig. 7.

Fig. 8.

effected by the action of the key; but as they may also be effected by pressure upon the end of the bolt, the security of locks in which such an arrangement is adopted, which are called *back-spring locks*, is much impaired.

Tumbler Locks.—We pass to the explanation of the second principle of security: that which consists in the use of moveable impediments to the motion of the bolt. *Fig. 8* represents a lock provided with a common tumbler. In this figure the bolt *a, b*, though shot backwards and forwards, has no spring or notches to catch on the back rim of the lock, to hold it in any required position; but it is provided with two notches in its upper edge, at *c* and *d*. Behind the bolt is a piece of metal called the *tumbler*, pivoted to the plate of the lock at *f*, and continually forced downwards by a spring which presses upon its upper edge. Near the end *e*, the tumbler carries a projecting stud, which, when the bolt is fully shot, falls into the notch *d*, and holds it firmly until, by the application of the key, the tumbler is lifted up to the position shown in the cut; by this action the bolt is released, so that the further turning of the key shoots it back, when the stud of the tumbler falls into the notch *c*, and again secures the bolt. So long as the tumbler remains in its proper notch, the bolt cannot be moved backwards or forwards by any pressure upon its ends; and the lock cannot be opened by any false key unless its bit be so formed as to reach the tumbler as well as the bolt. To render this more difficult the tumbler is often made to fall a little lower than the bolt, so as to be acted upon by a *step* formed on the bit of the key; while further security may be obtained by the use of two or more tumblers, which may be acted upon by different steps on the key. The great exactness requisite in the length of the bit forms a strong recommendation of even the commonest tumbler locks; for if the bit be ever so little too short it will not lift the tumbler out of its notch, while if it be but a very little too long, it will not enter the curved portion of the bolt.

The principle of security by tumblers has been known to the Egyptians from a very remote period. In the lock now commonly used in Egypt and Turkey, the bolt is secured by a number of pins, which fall into holes in the bolt when it is shot. In the annexed diagram, *a* is a part of the bolt, capable of sliding through the solid

Fig. 9.

piece *b*, in which are a number of hollows, *c, c, c*, each containing a moveable pin. If the bolt be slid forward until the holes *d, d, d*, come under the pins *c, c, c*, the lower ends of the pins will drop into them, and the bolt will consequently be held fast. It can only be released by the application of a key which has a series of pins exactly corresponding with the holes in the bolt, and which, being introduced into the bolt is pressed upwards to lift the pins clear of it. The security arises from the concealment of the obstacles, and from the circumstance

ent to any of the ordinary keys, and cutting additional notches in the sliders to suit it.

Owing to the small size of the protecting apparatus, the Bramah lock has been applied to many ingenious purposes for which other kinds of locks are less suitable, among which we may notice the locking of liquor-cocks. Mr. Mordan afterwards invented what he calls a "lock-protector," which is, in fact a shield, adapted to cover the key-hole, and having in its centre a minute lock with seven sliders. By applying this to a key-hole on the outside of a door, and turning its key a quarter round, two lancet-shaped pieces of steel are projected from a little box, in such a manner as to dig into the wood on the opposite sides of the key-hole, and to hold the shield so firmly in its place that nothing short of the application of violence can remove it, until, by a fresh application of the little key, the blades are withdrawn. A lock was invented by Mr. Kemp, in 1816, in which the peculiarities of both Barron's and Bramah's locks are combined in such a way as to afford, in the inventor's opinion, greater security than can be attained by either alone.

Permutation Locks. Of these, the simplest is a kind of padlock termed a puzzle-lock, which opens without a key, but is regarded rather as an ingenious toy than as an available substitute for locks. In the commonest form a bar, with square or other projections, is slipped through a series of circular discs, each of which is capable of being turned round upon it as an axis. The apertures through the centre of these discs are so formed that unless the whole of them are turned round to the exact position they occupied when the bar was slipped in, it cannot be withdrawn. To provide for bringing the rings to this position the periphery of each is marked with a series of letters or numbers, a certain predetermined combination of which must be brought into a straight line by turning the several rings round with the thumb and finger. As the number of combinations which may be effected, like the number of changes in the relative positions of the sliders of a Bramah's lock, is almost infinite, while only one combination will enable a person to open the lock, a high degree of security may thus be attained. Many varieties of this lock have been invented. One, by Mr. Mackinnon, is a tumbler lock, in which each tumbler is numbered, and a corresponding number is stamped upon each of a series of small plates, which, when put together upon an axis at the end of the shank of the key, as represented in *Fig. 17*, constitute a bit

Fig. 17.

resembling that of the key of an ordinary tumbler lock. Each bit is pierced with two holes, one of such a form as to fit upon the pear-shaped end of the shank, while the other is round, to receive a pin which is attached to the uppermost or end member of the bit, and which passes through all the others, as indicated by the dotted lines in *a*. A small hole in the end of the shank serves to receive a screw by which all the parts of the bit are kept firmly in their place. The end division of the bit, which is not numbered, is that intended to shoot the bolt; others, marked 1, 2, 3, 4, and 5, may be varied in position at pleasure, so as to correspond with similar changes in the positions of the tumblers, or so as to unfit the key for opening the lock. In some locks increased complexity is obtained by the use of two distinct sets of tumblers, capable of impeding each other's motion except when rightly acted upon.

Some locks have been made in which the action depends on the key being a powerful magnet. In others the difficulty of opening is increased by requiring a peculiar method of applying the key. In Lawson's lock there is a sliding curtain, by which, it is stated, "the key-hole is so perfectly closed during the act of unlocking, that it would be impossible to move the bolt while a pick remains in the aperture." In Gottlieb's lock, a piece of paper is so placed that no key can be put in without perforating it, and that it cannot be removed excepting by an application of the proper key. In Rutherford's lock, there is a stop-plate to the bolt, rendering it impossible to open the lock with its own key until, by the action of clockwork within or connected with the lock, the stop-plate should be brought into a certain position. Many contrivances have been effected for attaching an alarm to locks, by which the introduction of a false key should ring a bell or fire a pistol. The compound locks generally used for the doors of iron safes, and for similar purposes, though ponderous and complicated in appearance, are, in reality, of simple construction. Although they often throw out bolts on each side, and towards the top and bottom of the door, these are usually but so many branches of four massive pieces of iron, capable of being simultaneously projected or

retracted by a handle in the centre of the door; the actual lock being but small, and merely intended to move an apparatus by which the great bolts are themselves locked; so that the key may be small in proportion to the bolts by which the door is secured. Among the useful inventions relating to street-door locks is Chubb's combination-latch, which combines the simple lifting action of the ordinary French latch, or that which opens with a handle inside the door, and with a key from without, with much of the security of a tumbler-lock.

In the above description of the three principal classes into which locks may be grouped, we have only noticed a few examples in each class to illustrate the general principle. Our limits will not permit more detailed treatment. The number of patents relating to locks is immense, and every year is adding to it. In mentioning such celebrated makers as Chubb and Bramah, we have adverted chiefly to the original patents on which their locks were constructed; but numerous patents have subsequently been obtained by the same makers, which, though adhering pretty nearly to the same principle, exhibit wide diversities in detail. The earlier patents, too, have long since run out; and many other makers now construct locks involving the essential principles of the earlier Chubb and Bramah locks, though known by other names.

A very remarkable stimulus was given both to the invention and the manufacture of locks by occurrences which arose out of the Great Exhibition of 1851. Until that year, American locks were little known in England; but it then became known that great ingenuity had been displayed in this art beyond the Atlantic; and also, that the factory system, aided by machinery, was adopted to an extent far ahead of that followed by the lock-makers of England. Stansbury's lock, one of the American inventions, is a modification of the Egyptian lock. Yale's lock bears some resemblance to the Bramah; but it has two concentric cylinders working one within another. Andrews's bank-lock is constructed on the principle of changing the interior mechanism at pleasure, and adapting the moveable bits of the key to suit it, so as to produce a comparatively new lock by every change. Andrews's snail-wheel lock has a series of revolving discs to take the place of tumblers. Newell's lock, like Andrew's bank-lock, has a provision for altering the tumblers and key at pleasure without removing the lock from the door, or essentially altering its mechanism; but this is brought about by the use of two sets of tumblers, the one to receive motion from the other, and having different offices to fill; namely, the key to act upon the first series, and the second series to act upon the bolt. The American *parautoptic* (secret) bank-lock, invented by Mr. Newell when he found that his former lock was not proof against picking, contains a very elaborate series of primary and secondary tumblers, the positions of which are subject to curious changes by the action of the key itself; the owner can change the arrangement of the bits of the key at pleasure; these bits re-arrange the tumblers in the act of locking; and then the lock cannot be opened with the former arrangement of bits in the key. This lock obtained a high reputation in America and on the continent; and in 1851 Messrs. Day and Newell took out an English patent for it. Mr. Hobbs afterwards produced his protector-lock, a cheaper and more generally useful variety; it is a modification of the six-tumbler lock, and contains a small piece called a moveable stump, which resists the withdrawal of the bolt until acted upon by the proper key. Another lock by Hobbs has for its object the absolute closing of the key-hole during the process of locking, which is effected in a most curious but complicated manner.

Such are a few of the principal American locks. Long before the date of the Great Exhibition, the makers of those locks maintained an animated controversy respecting the merits of their several inventions, accompanied by challenges and prizes for the picking of the locks. Newell not only picked Andrews's unpickable lock, but picked his own also; and then set about devising new means of security—just as Vauban, having invented a particular system of fortification (his "first"), found out means of capturing fortresses constructed on that system, and then devised another system (his "second") to remedy the defects of the first. When similar lock-picking challenges and controversies took place, at a meeting of the Institute of Civil Engineers in 1850, the American exploits in this art were mentioned; but it was not till the following year that the matter acquired public notoriety. During the Great Exhibition in 1851, Mr. Hobbs made known his opinion that all English locks could be picked; he picked one made by Messrs. Chubb, to justify his belief; and then arose a warm controversy as to the question whether the operation was, under all the circumstances, fairly conducted. Messrs. Bramah had for many years had a most complicated lock, for the picking of which a prize of two hundred guineas was offered; Mr. Hobbs undertook this task, asked for thirty days to do it in, succeeded, and obtained the prize. But here again a discussion arose as to the fairness or unfairness of the process. And so it has been in other cases. Mr. Smith picked a Newell lock; but in a way which (it was contended), amounted only to a "ringing of the changes" among a certain number of combinations, and not a real picking. Messrs. Puckeridge and Parnell invented a lock, the picking of which was to be rewarded with a prize; the lock was picked, or at least opened, and the prize claimed; but a court of law decided against the claimant. If it would answer any useful purpose to notice other lock-picking exploits, there are ample materials for doing so; but it is obvious that all the challenges on this subject

are likely to be vitiated by various circumstances, and the results contested with angry feelings; for a man whose trade is that of making safety-locks would not be very ready to acknowledge the vulnerability of his own productions. The best result of these contests has been, that all the best locks have been made still better than before, by additional securities suggested by the contests themselves. Mr. Hobbs in 1853, picked a lock in a few minutes which had just won a prize from the Society of Arts—since which event it has been deemed better to let the lock-makers fight their own battles, without any testimonials or sanction from learned bodies. Mr. Denison has devised a lock in which a handle suffices to shoot or lock the bolt, but the unlocking cannot be effected except by the previous use of a very small key—an arrangement which he thinks likely to be useful in giving an employer much control over his clerks and others in the use of the lock.

The usefulness of this series of controversies has also been shown in the improvement of the manufacture of locks generally, both in efficiency and cheapness. Messrs. Hobbs and Ashley have introduced the American plan of manufacturing by machinery, ensuring both rapidity and exactness to a degree not attainable by mere hand-work; and it can hardly be doubted that English manufacturers must ultimately follow the same course. Mr. Price, of Wolverhampton, living in the very centre of the lock-making district, states that down to 1856, there was scarcely a machine of any kind used in the manufacture of locks and keys throughout the whole district. Wolverhampton makes most of the good locks, Willenhall nearly the whole of the common kinds; but in the one place, as in the other, the operations are almost wholly hand-work. The manufacture is mostly in the hands of small masters, each of whom works at the bench himself, and employs a small number of men and apprentices. The produce is sold to the Wolverhampton factors or merchants; and many of the small masters depend on the weekly receipts from the factors for the means of carrying on the next week's operations. There are very few lock-manufactories where the trade is conducted on anything like a large scale.

The principle and detail of modern lock-construction will be found fully treated in Tomlinson's 'Cyclopædia of Arts,' in the 'Rudimentary Treatise,' forming a part of Weale's Series; and in Denison's Essay, reprinted from the new edition of the 'Encyclopædia Britannica,' while Price's bulky volume (nearly 1000 pp.) on safes, locks, and keys, is a storehouse of gossip on all parts of the subject.

LOCKED JAW. [TETANUS.]

LOCUS. This word, or the Greek *τόπος*, signifying simply *place*, was used by the first geometers to denote a line or surface over which a point may travel, so as always to be in a position which satisfies some given condition. Thus, suppose it required to find the position of a point at which a given line subtends a right angle: the answer is, that the number of such points is infinite; for that any point whatsoever upon the surface of a sphere which has the given line for its diameter is such a point as was required to be found. This would be expressed as follows:—the *locus* of the point at which a given line subtends a right angle, is the sphere described on the given line as a diameter. If, however, the point were required to be in a given plane, its locus would no longer be the whole sphere, but only that circle which is the common section of the sphere and the given plane.

The following assertions are really nothing more than common propositions of geometry, stated in such a manner as to introduce the term locus. (1.) The locus of the vertex of an isosceles triangle described upon a given base is the straight line which bisects the base at right angles. (2.) The locus of the vertex of a triangle which has a given base and a given area is a pair of straight lines parallel to, but on different sides of, the base. (3.) The locus of the vertex of a triangle which has a given base and a given vertical angle, and which lies on a given side of the base, is an arc of a circle of which the given base is the chord; and so on.

The geometrical analysis of the Greeks depended much upon the investigation of loci, and the method of using them will sufficiently appear by one instance. Suppose, for example, it is required to describe a triangle of given area and given vertical angle upon a given base. Laying down the given base, it is easy to draw the parallel which is the containing line, or locus, of the vertices of all the triangles which have the given area; and also, upon the same side, the arc of the circle which is the locus of the vertices of all the triangles having the given vertical angle. If then the parallel and the arc of the circle intersect, the point or points of intersection are obviously the vertices of triangles which satisfy all the required conditions; if they do not intersect, the problem is impossible. When the locus of all the points satisfying a given condition cannot be ascertained by elementary geometry, and when this locus is therefore taken for granted, we have the species of solution which was called *mechanical*. An instance of this will appear in the article *TRISECTION OF THE ANGLE*.

It is to be understood that no curve whatever is called the locus of a point, unless any point whatsoever of that curve may be taken as the point in question. Thus, if each of six points should satisfy certain conditions, all lying upon a given circle, and if no other point of the circle should satisfy those conditions, that circle would not be called the locus of the points.

LODGINGS, in the law of landlord and tenant, is applicable only to

apartments let for habitation in the same house with another; and whether the apartments be furnished or no, the law is the same.

The letting, as it comprises an interest in land, should satisfy the 29 Car. II. c. 3 § 4 by being in writing, and must, when produced in court, appear to be signed at least by the party against whom it is produced. Such letting entitles the lodger, without express mention for that purpose in the contract, to the use of all those conveniences which are properly common to the inmates of the same house, and necessary to the comfortable use of his apartments, such as door-knocker, door-bell, water-closet, and the like, the withdrawal of any of which by his landlord may be a ground of action for the lodger.

During the term of occupancy, if any of the lodger's goods are lost or stolen from the house, the landlord is not liable to make good the loss, as an innkeeper would be, unless it appear that he was privy to the wrong. On the other hand, if rent is in arrear to the superior landlord he may distrain on the goods of the lodger found in the house, notwithstanding no rent is due from him to the mesne landlord; the lodger's remedy in that case being against his immediate lessor, by action at law for the value of the goods taken.

The term for which lodgings are let may extend to any period whatever, with this difference however as to the instrument of contract, that it must be by deed if the term exceeds three years by so much as a day. Usually, however, such apartments are let for a portion of a year merely—it may be six months, a quarter of a year, a month, or a week—and the rent, if not a gross sum for the whole period, may be stipulated as payable by the week, month, or other convenient period. If it appear by the contract, taken as a whole, that it was for a period absolutely, the tenancy expires with the end of the time, and there is no necessity for notice to terminate it. But if it appear that both parties to the contract contemplated a continuing tenancy, terminable by either on giving the usual notice, it then becomes a question what notice must be given. It is by no means certain that a weekly tenant is bound, in the absence of usage or contract, to give any notice whatever of his wish to end the tenancy; in London he must give a week's notice, but that depends on the custom. Some text-writers have inferred that monthly, quarterly, or half-yearly tenancies are only terminable by a notice of equal length with the tenancy. No doubt such a notice would be sufficient, and it is the safer course to adopt when convenience will allow. But in the absence of any contract between the parties, it does not appear but that a month's notice, terminating with the end of the period, would suffice to determine a tenancy for any shorter time than a year. Where a person hired furnished apartments for three months, and a receipt was given for the rent payable for the whole period, but at the end of the time he continued still to occupy, it was held that the jury might infer from these circumstances that the tenancy was continued afterwards from week to week.

The 7 & 8 Geo. IV. c. 29, § 45, protects the property of those who let lodgings from the dishonesty of their tenants by making it felony for the person in occupation to steal or appropriate any chattel or fixture allowed to be used in any house or lodging.

On this subject see further Woodfall, *Landlord and Tenant*.

LOG and LOGLINE. The apparatus by which the velocity of a ship's motion through the water is measured. If at any moment a piece of wood, or other light substance, be thrown out of a ship while sailing, as soon as it touches the water it ceases to partake of the ship's motion; the ship goes on, and leaves it behind. If then after a certain interval, say of half a minute, the distance of the vessel from the floating body be accurately measured, the rate of the ship's motion through the water will be ascertained; we do not say the actual rate of the ship's going, but only that of its motion through the water, because in many cases currents exist, and the wood itself is carried along; consequently the true rate cannot thus be known.

This is the principle of the log: in practice the log is a flat piece of wood, generally of the figure of a quadrant, loaded with lead on its arc, to make it float upright; to this is attached a line about 150 fathoms long, divided into equal lengths by little pieces of knotted twine rove into it. These divisions begin about twenty or thirty yards from the log, where a piece of red rag is usually fastened, in order to show the place readily. All the line between the log and the rag is called the stray line, and is of course omitted from the account. When the log is thrown into the sea, which is done from the lee quarter of the vessel, the log-line, by the help of a reel on which it is wound, is immediately veered out, at least as fast as the ship sails; as soon as the red rag leaves the reel, a half-minute glass is turned, and when the sand is all run down, the reel is stopped. Then by measuring the quantity of line run out, the distance sailed by the vessel in half a minute is known, and by calculation its rate of going per hour. There are various ways of dividing the line, the most usual of which is to place the knots at distances of 50 feet from each other; now as 120 times half a minute make an hour, and 120 times 50 feet make almost a geographical mile, so many knots will run from the reel in an experiment as the vessel sails miles in the hour; from this comes the expression of a vessel's sailing so many knots an hour—meaning miles. Fifty-one feet would be more accurately 120th part of a mile than 50 feet; but it is found practically that the ship's way is always a little more than that given by the log, arising from the circumstance that the line is unavoidably pulled in some degree, and the log is consequently

not a fixed point; it is moreover safer to have a ship behind the reckoning than before it, which induces many commanders to shorten the distances between the knots to forty-eight and even forty-five feet. Whatever distance be taken, it is found convenient to subdivide into ten parts for decimals of a mile. Careful commanders remeasure the log-line frequently, to ascertain if it varies from its original length. In case of an alteration they apply a correction to the rate found by a common process in the rule of three—as the length which the commander reckons upon is to the real interval, so is the apparent rate to the true rate. A similar correction is required if the half-minute glass is found to be wrong.

In the best regulated vessels the log is hove every hour; and in calculating the ship's going it is supposed that the rate has not varied between the intervals of heaving; but if the wind has sensibly varied, or more or less sail has been set during the time, then an allowance is made according to the discretion of the person who keeps the account.

A few years ago a very curious log was invented by Mr. Hookey, which though ingenious was too complex to come into general use; its object was to afford as great a resistance as possible to the pull of the line, and at the same time to be easily drawn back to the ship when its work was done. This log is shaped like a fish, and the line is in its mouth.

A more practically useful suggestion of Mr. Hookey was to soak the line in a mixture of three parts linseed oil and one part fish oil, which prevented its shrinking; a matter of no small importance when it is considered that a new line without preparation will lose 50 or 60 feet of its length by contraction when wetted.

Of late years Massey's patent log has been used with great benefit to navigation, as the time being noted when it is put overboard, it may be allowed to tow a-stern for hours, at the expiration of which the number of revolutions of a vane attached to it, may be read off from a self-registering dial, and compared with the time, from which is deduced the ship's velocity. Its form is too well known to need further description.

LOG-BOARD AND LOG-BOOK. These contain the account of the ship's progress, as deduced from observations of the log. The log-board is either a large piece of plank, blackened, ruled, and prepared for writing on with chalk, or else a slate with divisions scratched upon its surface. As soon as the seaman has hove the log, and the rate of motion is ascertained, the number of knots, with the odd tenths, or odd fathoms, eight of which equal one knot, are written on the board, each in its proper ruled column; also the course of the vessel, the direction of the wind, and any remarks made at the moment. This is repeated every time the log is hove, and once in twenty-four hours the whole is copied into a book called the log-book, which is ruled for the purpose in the same way as the log-board, and in which also all the transactions relative to navigation are inserted, such as bearings and distance of lands, rocks, and shoals, the direction and velocity of currents, the state of the weather, and also whatever principal operations are performed in the ship, such as reefing topsails, tacking, wearing, &c. It is also usual to set down every day the whole course and distance run, calculated from the results of all the several trials made by the log, with the distance and bearing of some port to which the ship is approaching. The account thus obtained is technically termed dead-reckoning, and is never quite correct, being subject to all the errors caused by changing the direction and velocity in the intervals of observing, by the sort of guess usually made at the course and rapidity of currents, and at the amount of the falling off of the vessel from its apparent course, technically called lee-way. The dead reckoning is however necessarily used until an opportunity is afforded of taking observations for latitude and longitude, or until some place whose position is known comes in sight; the true place of the ship is then substituted in the log-book for that obtained by dead reckoning, and from that place subsequent reckonings are made until another observation.

By 17 & 18 Vict. c. 104, the Board of Trade sanction certain forms of log-books (called *official logs*) as adapted to certain kinds of voyages, and it is rendered imperative on every commander to see that all entries therein be made as soon as possible after the occurrences happen which are therein noted.

The official log-book is supposed to contain, in addition to the nautical memoranda above named, a faithful register of every crime and offence, with their punishment, on board the ship; every case of accident or illness, with particulars of treatment; the cause of every death; a register of births; every marriage; the sale of deceased seamen's effects; the character of each of the crew, or sufficient reasons for withholding the opinion thereupon; a full account of all accidents to the ship and stores; details of collisions, &c.: indeed the ship's log-book forms not only a complete history of the voyage, but adds to our knowledge of marine statistics, and thus furthers materially the interests of commerce, while its records promote the ends of justice, for entries in the official log are received as evidence in any court of law.

Nor is commerce alone the gainer by attention to the log-book. Remarks on temperature, winds, weather, and indeed all notable diurnal phenomena, have, by indefatigable comparisons and well digested deductions, enlightened the meteorologist; while the hydrographer has

enriched with no less zeal the treasures of nautical science from the mere notes of the observant sailor. These would seem to be the only legitimate subjects which claim a navigator's attention in keeping his log-book, but the progress of education among sea-officers is shown year by year in a manner as pleasing as it is important. The zoologist, the natural historian, and indeed the philosopher himself, perceive and acknowledge the vast benefits which a judicious naval observer may yet confer on science. The field for research is a wide one: the heavens, the atmosphere, the ocean, each yields its quota of absorbing interest and improving pastime to the intelligent sailor, and impressions as indelible as they are ennobling lead him insensibly towards social elevation. Little indeed should we know of currents, trade winds, the gulf stream, dust showers, &c., but for the seaman's "log-book," official or private.

LOGARITHMIC CURVE and LOGARITHMIC SPIRAL. The former has for its rectangular equation $y = a^x$, and its most remarkable property is that its subtangent is the same at every point of the curve.

The latter has $r = ca^\theta$ for its polar equation, and its tangent always makes the same angle with its radius vector; whence it is called the equiangular spiral.

LOGARITHMS. The etymology of this word is *λογῶν ἀριθμός*, the number of the ratios; and the reason for the appellation will appear in the course of this article. We assume that the reader has the common knowledge of logarithms, and of the method of using them.

We have abandoned the intention of giving a view of the rise and progress of logarithms, for the following reasons. The subject is now one of such wide extent, when its theory and practice are both included, that it would be like writing the history of a complete science to put together all that would be needed in an article professing to show the past and present state of logarithmic algebra, as well as of logarithmic computation. If we were to confine ourselves to the latter only, the view of the subject would be too confined. And since the elements of the subject now usually given are clothed in the most modern algebraical form, it would take considerable space to explain at length the process of the early writers in terms intelligible to those who are not conversant with their writings. We shall therefore devote the first part of this article to such explanations as will enable the student, fresh from modern books of algebra, to read the various histories which exist with facility: and we shall then point out how to deduce the principal formulæ connected with logarithms.

The early history of logarithms will be found at length in the preface to Dr. Hutton's Tables; in the 'History of Logarithms' contained in the first volume of Dr. Hutton's Tracts, in Delambre's 'Histoire de l'Astronomie Moderne,' vol. i. pp. 491–568. See also TABLES, and, in the BIOG. DIV., NAPIER, BRIGGS, GUNTER, KEPLER, MERCATOR, &c.

The idea of logarithms originally arose (in the mind of Napier) from the desire to make addition and subtraction supply the place of multiplication and division. A table, in which are registered 1, a , a^2 , a^3 , &c., supplies this desideratum to a certain extent; for since a^x multiplied by a^y gives a^{x+y} , we find the product of the first by adding their exponents, and looking in the table for the $(x+y)$ th power. Thus for the set 1, 2, 4, 8, 16, &c., a table of logarithms is easily constructed, a specimen of which is as follows:—

Num.	log.	Num.	log.	Num.	log.
1	0	32	5	1024	10
2	1	64	6	2048	11
4	2	128	7	4096	12
8	3	256	8	8192	13
16	4	512	9	16384	14

Thus, to multiply 64 and 128, that is, to find the product of the sixth and seventh powers of 2, we must take the $(6+7)$ th or 13th power, which, from the table, is 8192.

Such a table would be useless for general purposes, since it omits more numbers than it contains. But if we take a very little greater than unity, the powers will increase but slowly, and every whole number within given limits may be made either a power of a , or very near to a power of a . Suppose, for instance, that we wish for a table of logarithms which shall contain among its numbers either every whole number under a million or a fraction within h of every number under a million. Extract the square root of one million, the square root of that square root, and so on, until, say the r th root of one million has been extracted, and let this r th root be $1+t$. It is obvious that this extraction may be carried on until t is small as we please. Consequently $(1+t)^r$ is a million, and every lower power of $1+t$ is less than a million, so that (m standing for a million) no two consecutive powers differ by so much as the difference of m and $m(1+t)$, or by so much as mt . If then we proceed with the extraction until mt be less than h , we shall have t of the degree of smallness required: that is, since every whole number less than m lies between two powers of $1+t$, having exponents less than r , *à fortiori* every such whole number must be within h of some power of $1+t$.

This is in fact the first view which was taken of the method of constructing tables of logarithms; and it must be remembered that Napier was not in possession of the modern way of expressing the powers of quantities. On the methods of facilitating such enormous

computations, and on the details which still remained for the first calculators after they had applied all the analysis which they had, we have not here to speak; but we shall now show how the table may be formed by mere labour, and how the word logarithm arises.

Let us suppose that our system is to be such that 0 being the logarithm of 1, a hundred thousand shall be the logarithm of 10. If the hundred-thousandth root of 10 be extracted and called $1+t$, it would be found that 2 is very nearly the 30103rd power of $(1+t)$, that 3 is very nearly the 47712th power of $1+t$, and so on. If then, beginning with 1, we increase it in the ratio of 1 to $1+t$, giving $1+t$; if we increase this in the ratio of 1 to $1+t$, giving $(1+t)^2$, and so on, it appears that we shall reach 2 (or very near to it, one way or other), when 30103 such ratios have been taken; or if we pass from 1 to 10 by 100000 steps, increasing each time in the same ratio, we shall come nearest to 2 in 30103 steps, which is therefore the number of times the increase is made in a certain ratio, or the number of the ratios, the $\lambda\gamma\omega\nu\ \acute{\alpha}\rho\iota\theta\mu\acute{o}\varsigma$, or the logarithm, of 2.

In such a table it must of course follow that the logarithm of a product is exactly or very nearly the sum of the logarithms of the factors, since for instance 2 being $(1+t)^{30103}$ and 3 being $(1+t)^{47712}$ very nearly, 6 must be very nearly $(1+t)^{77815}$. Nor is this property altered, if we divide or multiply all the logarithms by the same number. If then we divide every logarithm by 100000, the logarithm of 10 becomes 1, that of 2 becomes .30103, and that of 3 becomes .47712, as in the common tables.

The first step of importance which was made in the logarithmic analysis was the following. If t be very small, the lower powers of $1+t$, the square, cube, &c., are $1+2t$, $1+3t$, &c., very nearly; or if m and n be not so great but that mt and nt are still small, the m th and n th powers of $1+t$ are $1+mt$ and $1+nt$ very nearly. But the logarithms of these powers are m and n ; that is, if k and l be small, the logarithms of $1+k$ and $1+l$ are very nearly in the proportion of k to l . If then we take two numbers, a and b , and extract a very high root (say the r th) of both, so that the results are very near to unity, say $1+k$ and $1+l$, we have (nearly)

$$\log. \sqrt[r]{a} : \log. \sqrt[r]{b} :: k : l.$$

But the two first terms are in the same ratio as $\log a : \log b$, since the multiplication of the former terms by r gives the latter. Consequently, when the logarithm of one number is known, that of any other can be found to any degree of nearness. We shall presently see this in a clearer form; it is sufficient here to show how the theorem was first obtained. If to the preceding methods we add that of INTERPOLATION, which Briggs used with success, we have before us the bases of the original computations of logarithms.

It was evident from the first that the connection between a logarithm and its number must be of the following kind: when the logarithm increases in arithmetical progression, the number must increase in geometrical progression; so that if a and $a+b$ be the logarithms of A and AB , then $a+2b$, $a+3b$, &c., must be the logarithms of AB^2 , AB^3 , &c. Several mathematicians had formed this conception; but the preliminary difficulty which stopped their progress was their being unable to present the series of natural numbers (or fractions of a high degree of nearness to them), in the shape of terms of a geometrical progression. The great merit of Napier is threefold: first, he distinctly saw that all numbers, within any given limit, may be either terms, or as near as we please to terms, of a geometrical progression; secondly, he had the courage to undertake the enormous labour which was requisite for the purpose; thirdly, he made an anticipation of the principle of the differential calculus in developing the primary consequences of the definition.

The predecessors of Napier probably did not well understand the notion of a quantity varying in geometrical ratio, while another varied simultaneously, but in an arithmetical ratio. The difficulty is that which a beginner finds in seizing the notion of compound interest carried to its extreme limit, so that every fraction of interest, however small, begins to make interest from the moment it becomes due. We have preferred to omit this consideration in the article INTEREST, where it would have been of no practical use, and to introduce it here, where it may aid in the explanation of the first principles of logarithms.

Let £1 become £ $(1+r)$ in a year, and consequently, at the same rate of interest, it becomes £ $(1+r)^n$ in n years. Suppose however that interest, instead of being payable yearly, is paid z times in a year, and that interest makes interest from the moment it is paid. Consequently, at the end of the first, second, &c. fractions of a year, the pound first put out becomes

$$1 + \frac{r}{z}, \left(1 + \frac{r}{z}\right)^2, \left(1 + \frac{r}{z}\right)^3, \dots$$

or $\left(1 + \frac{r}{z}\right)^z$ at the end of one year, and $\left(1 + \frac{r}{z}\right)^{nz}$ at the end of n years.

If we may make z as great as we please, that is, if we may make payments of interest follow one another as quickly as we please, we may make the increase of the pound approach as nearly as we please to a gradual increase, of which it must be the characteristic that in

Successive equal times the amounts are in geometrical progression. Let AB become AC in a time represented by bc . Divide bc into

any number of equal parts, and in the successive equal times bp , pq , qr , &c., let a point move through BP , PQ , QR , &c. In the article ACCELERATION is explained the manner in which a succession of impulses, sufficiently small in amount, and often repeated, may be made to give, as nearly as we please, the results of a perfectly gradual motion. At B let a velocity be given sufficient to carry the point to P in the time bp ; at P let an impulse be given which would cause PQ to be described in the time pq , and so on. And let AB , AP , AQ , &c., be a continued set of proportionals, namely, $AB : AP :: AP : AQ :: AQ : AR$, &c. Increase the number of subdivisions of bc without limit, and we approach as a limit to gradual motion of such a kind that the distances of the point from A , at the end of any successive equal times, shall be in continued proportion. To show this, suppose we compare the motion from B to C with any other part of the motion described in some subsequent time $b'C'$ (equal to bc), and which carries the moving point from B' to C' . Divide the time $b'C'$ into as many equal parts, $b'p'$, $p'q'$, &c., as before, and let $B'P'$, $P'Q'$, &c., be the lengths described in the second set of subdivisions. Then by the law of the motion $AB : AP :: AB' : AP'$, whence BP and $B'P'$ are in the ratio of AB to AB' ; and similarly PQ and $P'Q'$ are in the ratio of AP to AP' , that is, of AB to AB' ; and so on. Consequently, the sum of BP , PQ , &c., or BC is to the sum of $B'P'$, $P'Q'$, &c., or $B'C'$, in the same ratio of AB to AB' ; whence also AC is to AC' as AB to AB' , or $AB : AC :: AB' : AC'$. That is, if in any one time the distance from A increases from x to y , and in any other equal time from x' to y' , then $x : y :: x' : y'$. From which it readily follows that the distances attained at the ends of successive equal times are in continued proportion.

More than this, the velocities of the moving point at B and B' are as BP to $B'P'$ (these being spaces described in equal times): and the ratio of these, however many may be the number of subdivisions, is always that of AB to AB' . Hence a gradual motion of the character described is one in which the velocity of the moving point increases in the same proportion as the distance from A .

In the preceding diagram, the time elapsed from B to C is the logarithm of AC , that of AB being 0. An infinite number of systems may be constructed, depending on the different velocities with which the moving point may be supposed to start from B . In Napier's system, at least in that system stripped of certain peculiarities not worth noting at present [TABLES], AB being a unit, the point starts from B at the rate of a unit of space (AB) in a unit of time: obviously the most simple supposition which can be made, and which has procured for this system the distinctive title of *natural logarithms*. In Briggs's system the point starts from B with such a velocity that (AB being 1) it shall have attained 10 times AB in one unit of time. This requires, as we shall see, an initial velocity of 2.302585... times AB in one unit of time.

In addition to the principles here laid down, a known property of the hyperbola very early showed that logarithms would become applicable to geometry: and thus it happened that the first decidedly algebraical step in the computation of logarithms was announced in Mercator's 'Logarithmotechnia,' as the quadrature of the hyperbola. Let AE and AG be the asymptotes of an hyperbola, and let AB , AC , AD , &c., be in continued geometrical progression. Draw BK , CL , DM , &c., parallel to the other asymptote AG , then the hyperbolic trapezia $BKLC$, $CLMD$, $DMNE$, &c., are equal, or $BKLC$, $BKMD$, $BKNE$, &c., are in arithmetical progression. So that any trapezium $BKMD$ is a logarithm to its terminal abscissa AD . This property was the discovery of Gregory St. Vincent, who published it in his 'Opus Geometricum,' Antwerp, 1647. It was therefore unknown both to Napier and Briggs.

We shall now take the question of logarithms, availing ourselves of the power of modern algebra.

Definition.—By the logarithm of a number let any such function of that number be understood as has the following property. When x is to y as x' is to y' , the logarithm of x exceeds or falls short of the logarithm of y by as much as the logarithm of x' exceeds or falls short

of that of y' . Let ϕx be the function which a number is of its logarithm: so that $x = \phi(\log x)$. If then a and $a+b$ be logarithms of x and y , and if c be the logarithm of x' , then as $x : y :: x' : y'$, $c+b$ must be the logarithm of y' . And x, y, x' and y' are severally ϕa , $\phi(a+b)$, ϕc and $\phi(c+b)$. But $xy' = x'y$, or

$$\phi a \times \phi(c+b) = \phi c \times \phi(a+b).$$

Let ϕa or x be the number which has 0 for its logarithm; then $a=0$; and calling N the number in question, we have

$$N \times \phi(c+b) = \phi c \times \phi b,$$

$$\text{or } \frac{\phi(c+b)}{N} = \frac{\phi c}{N} \times \frac{\phi b}{N}.$$

But by the theorem proved in the article BINOMIAL THEOREM, this can only be true on the supposition that $\phi c \div N$ is such a function of c as c^c , where c is independent of N . Consequently, the number whose logarithm is c must be Nc^c . This evidently satisfies the conditions, and the theorem quoted shows it to be the only function which satisfies the conditions.

It is most convenient to assume 1 as the number N , which has 0 for its logarithm. We have then the following equation, connecting a number with its logarithm,

$$c^{\log x} = x;$$

so that every number has a logarithm for any value of c we may take, only it must be remembered that the same value of c must always be used. The logarithms of all numbers for a given value of c form a system: and c is called the *base* of that system.

Given a system of logarithms, we now inquire how to find the logarithms in any other system. Let A and B be the bases of the systems, and a and b the logarithms of any number x in the two bases. Then we have

$$A^a = x, B^b = x, \text{ or } A^a = B^b;$$

$$\text{whence } B = A^{\frac{a}{b}}, \text{ or } \log B \text{ (base } A) = \frac{a}{b},$$

$$b = \frac{a}{\log B \text{ (base } A)}, \text{ or } \log x \text{ (base } B) = \frac{\log x \text{ (base } A)}{\log B \text{ (base } A)};$$

that is, to turn one system of logarithms into another with any new base, divide every logarithm in the system by the logarithm which there belongs to the new base.

We now proceed to the method of determining logarithms. In the article LIMIT it is shown, by means of the binomial theorem, that of the two series

$$1 + a + \frac{a^2}{2} + \frac{a^3}{2 \cdot 3} + \frac{a^4}{2 \cdot 3 \cdot 4} + \dots;$$

$$1 + ax + \frac{a^2x^2}{2} + \frac{a^3x^3}{2 \cdot 3} + \frac{a^4x^4}{2 \cdot 3 \cdot 4} + \dots;$$

the second is the x th power of the first. A remarkably simple case presents itself, which, in fact, leads to Napier's system of logarithms: it is when $a=1$. In this case the first series becomes

$$1 + 1 + \frac{1}{2} + \frac{1}{2 \cdot 3} + \frac{1}{2 \cdot 3 \cdot 4} + \dots;$$

which is very convergent, and is 2.718281828, very nearly. This remarkable series is generally denoted by e (sometimes by ϵ , Laplace always uses c for it), and we have

$$\epsilon^x = 1 + x + \frac{x^2}{2} + \frac{x^3}{2 \cdot 3} + \dots$$

In Napier's system, then (we shall presently show that this is Napier's system), x is the logarithm of $1 + x + \frac{1}{2}x^2 + \dots$; or the logarithm being given, the number can be immediately found.

Since the last equation is universally true, for x write $\log a \times x$, where $\log a$ means $\log a$ (base ϵ). The first side then becomes

$$\epsilon^{\log a \times x}, \text{ or } (\epsilon^{\log a})^x, \text{ or } a^x;$$

$$a^x = 1 + \log a \cdot x + \frac{(\log a)^2 \cdot x^2}{2} + \dots;$$

$$\frac{a^x - 1}{x} = \log a + \frac{(\log a)^2 \cdot x}{2} + \dots$$

if x be diminished without limit, we have then

$$\text{Limit of } \frac{a^x - 1}{x} = \log a \text{ (base } \epsilon);$$

or, for a given (and very small) value of x , the logarithms of different numbers (a) are very nearly in the proportion of the values of $a^x - 1$. This is the theorem to which we have before alluded.

Let $a = 1 + b$, then

$$(1+b)^x = 1 + xb + x \frac{x-1}{2} b^2 + x \frac{x-1}{2} \frac{x-2}{3} b^3 + \dots$$

$$\frac{(1+b)^x - 1}{x} = b + \frac{x-1}{2} b^2 + \frac{x-1}{2} \frac{x-2}{3} b^3 + \dots;$$

if x diminish without limit, the limit of the first side has been shown to be $\log(1+b)$, the base being ϵ , which is always to be understood when the contrary is not expressed. The limit of the second side is easily found by making $x=0$, and we thus have

$$\log(1+b) = b - \frac{b^2}{2} + \frac{b^3}{3} - \frac{b^4}{4} + \dots,$$

which however is only convergent when b lies between -1 and $+1$. Since this last is universally true, we find, by substituting $-b$ for b ,

$$\log(1-b) = -b - \frac{b^2}{2} - \frac{b^3}{3} - \frac{b^4}{4} - \dots;$$

and subtracting the first from the second, remembering that

$$\log(1+b) - \log(1-b) = \log \frac{1+b}{1-b},$$

we find that

$$\log \frac{1+b}{1-b} = 2 \left\{ b + \frac{b^3}{3} + \frac{b^5}{5} + \dots \right\}$$

$$\text{Let } \frac{1+b}{1-b} = x, \text{ or } b = \frac{x-1}{x+1};$$

$$\log x = 2 \left\{ \frac{x-1}{x+1} + \frac{1}{3} \left(\frac{x-1}{x+1} \right)^3 + \dots \right\},$$

which is always convergent, but converges very slowly when x is considerable. If however we make

$$x = \frac{z+1}{z}, \text{ or } \frac{x-1}{x+1} = \frac{1}{2z+1};$$

then, remembering that $\log \frac{z+1}{z} = \log(z+1) - \log z$, we have

$$\log(z+1) - \log z = 2 \left\{ \frac{1}{2z+1} + \frac{1}{3} \frac{1}{(2z+1)^3} + \dots \right\},$$

which is very convergent when z is even so small as 1, and serves to find the logarithm of any number when that of the next lower number is given. The two following series, which may be easily proved from the preceding, will complete the list of those which are most useful in practice:

$$\log(z+a) = \log z + \frac{a}{z} - \frac{1}{2} \frac{a^2}{z^2} + \frac{1}{3} \frac{a^3}{z^3} - \dots;$$

$$\log(z+a) = \log z + 2 \left\{ \frac{a}{2z+a} + \frac{1}{3} \left(\frac{a}{2z+a} \right)^3 + \dots \right\}.$$

It only remains to show the identity of this system with that of Napier. If t be the number of seconds elapsed from the beginning of a motion, and if a^t be the length described in that time, then the time is the logarithm of the length described. The *velocity* at the end of t seconds is the differential coefficient of a^t , or $a^t \cdot \log a$, where the logarithm used is that of the preceding algebraical system; this velocity is therefore $\log a$ at starting, or when $t=0$. Now, in Napier's system this velocity is unity, or $a=\epsilon$: that is, the base of Napier's logarithms is the series called ϵ . But in the system whose base is 10, $\log a$ is 2.3025851, which is the velocity at starting assumed by Briggs.

By the foregoing series a system of Napierian logarithms may be calculated with a very small fraction of the labour which they cost their inventor. This having been done for all whole numbers within the given limits, the logarithm of any fraction is readily found by subtracting the logarithm of the denominator from that of the numerator.

It must be admitted that Briggs, by his construction of the decimal system, divides with Napier the merit of inventing logarithms, considered as an instrument of calculation. In the Napierian system the table must either be carried to an enormous length, or whole numbers only must have logarithms, and every logarithm of a fraction will require two entries of the table and a subtraction. But in Briggs's system the logarithm of every decimal fraction can be found by one entry of the table, and one inspection of the fraction.

The peculiarity of this system (the base of which is 10) is as follows: Every number or fraction is either a power of ten, positive or negative, or lies between two powers of ten. The powers of ten are ranged in the following table:—

.....		
$10^{-4} = .0001$	$10^0 = 1$	$10^1 = 10$
$10^{-3} = .001$		$10^2 = 100$
$10^{-2} = .01$		$10^3 = 1000$
$10^{-1} = .1$		$10^4 = 10000$
		

From which the following rules may easily be obtained: a number which has m figures before the unit's place lies between 10^{m-1} and 10^m , and its logarithm therefore lies between $m-1$ and m , or it is $m-1$ + a fraction less than unity. Also, if a fraction be less than unity, and if its first significant figure lie in the n th decimal place, this fraction lies between 10^{-n} and $10^{-(n-1)}$; so that its logarithm is $-n$ + a fraction less than unity. Now the convenience of Briggs's system lies in this, that the fraction less than unity, which is a part of every logarithm, does not depend on the position of the decimal point, but entirely upon the significant figures: the reason being, that an alteration of the position of the decimal point being a multiplication or division by some whole power of 10, alters the logarithm by the addition or subtraction of a whole number. This question is discussed in every treatise on the mode of using logarithms.

Let a be the base of a system of logarithms, and let $\log x$ signify simply the Napierian or natural logarithm of x ; then by the theorem already proved

$$\log (\text{base } a) = \frac{\log x}{\log a} = \frac{1}{\log a} \cdot \log x.$$

The factor $1 \div \log a$, which converts Napierian logarithms into those whose base is a , is called the *modulus* of the system whose base is a . In Briggs's system this modulus is .4342945 nearly, and the logarithms of this system being called *common* or *tabular* logarithms, we have—

$$\text{common log } x = .4342945 \times \text{Nap. log } x$$

$$= \frac{43}{99} \times \text{Nap. log } x, \text{ very nearly.}$$

$$\text{Nap. log } x = 2.3025851 \times \text{com. log } x,$$

$$= \left(\frac{100-1}{43} + \frac{1}{4000} \right) \times \text{com. log } x.$$

LOGARITHMS, GAUSS'S. These are tables suggested by the celebrated Gauss for supplying an inconvenience connected with the use of logarithms described in § 21 of the article LOGARITHMS, USE OF. Though they have been suggested more than fifty years, they are only beginning to receive the attention which they merit.

If $\log a$ and $\log b$ be given, and $\log (a + b)$ or $\log (a - b)$ be wanted, the ordinary tables can only be applied by finding a and b from their logarithms, adding or subtracting them as found, and then finding the logarithm of the sum or difference. This requires three uses of the tables, and one process of addition or subtraction. Gauss's table substitutes one use of a table, and two processes of addition or subtraction. When the above necessity occurs only now and then, it may be hardly worth while to have recourse to such a table; but in any series of calculations in which the determination of $\log (a \pm b)$ from $\log a$ and $\log b$ is a frequent constituent part, the table is a very great relief.

The construction of the table is as follows: There are three columns styled A, B, C; the first, A, containing the *arguments*. [TABLE.] Also B and C are furnished with differences and tables of proportional parts, in the same manner as the seven-figure logarithms. In column A are entered successive decimal fractions, in a manner depending upon the extent of the table. In the one we shall mention, A contains .0000, .0001, .0002, &c., up to 2.0000; then 2.001, 2.002, &c., up to 3.000; then 3.01, 3.02, &c., up to 4.00; then 4.1, 4.2, &c., up to 5.0, followed by 6 and 7. And whatever an A may be the logarithm of,

say N, then its B is the logarithm of $1 + \frac{1}{N}$, and its C is the logarithm of $1 + N$. Thus, opposite to 2.00 in A, which is the logarithm of 100, the B is $\log 1.01$, the C is $\log 101$; accordingly in one part of the table we see

A	B	C
2.00	.0043214	2.0043214

Again, in another part of the table we see

A	B	C
.4845	.1031058	.6076058

And it will be found that .4845 being the logarithm of N (not mentioned; it is 3.041406), .1031058 is the logarithm of $1 + 1 \div N$, and .6076058 of $1 + N$.

The manner of using this table is as follows: Let x and y be two numbers, of which x is the greater, and let $\log x$ and $\log y$ be given. Then

1. To find $\log (x + y)$. Let $A = \log x - \log y$
 $\log (x + y) = \log x + B = \log y + C$
 2. To find $\log (x - y)$. Let $B = \log x - \log y$
 $\log (x - y) = \log y - A = \log x - C$
- Or thus: Let $\log x - \log y = C$
 $\log (x - y) = \log y + A = \log x - B.$

It seems as if this were two tables, each of which might serve all purposes. And it is true that $\log (x + y)$ can always be found from either table. But the B table begins from .3010300 or $\log 2$, and *descends*, while the C table begins from the same, and *ascends*. Consequently, .23, for

instance, cannot be found about the C's, nor .32 among the B's. So that in finding $\log (x - y)$, $\log x - \log y$ must not be made B if it be greater than $\log 2$, nor C if it be less.

For a list of tables published in aid of the above method, see TABLES.

LOGARITHMS, HYPERBOLIC. As tables of hyperbolic logarithms are not very frequently met with, the following table is given to facilitate the finding of the hyperbolic logarithm by means of the common one. It is in fact a table of the hyperbolic logarithms of the powers of 10: thus opposite to 12 we see 27.63102112, which is the hyperbolic logarithm of 10^{12} , or a million of millions.

To find the hyperbolic logarithm of a number, multiply the common logarithm of that number by 2.30258509, by means of the table. Set down the number opposite to the integer of the logarithm, then that opposite to the first pair of decimal figures, leaving out the two last figures, then that opposite to the second pair, leaving out the four last figures, and so on. Add the results together. But if the characteristic of the common logarithm be negative, subtract the united results of the pairs of decimal places from the result of the characteristic, and make the answer negative. For example, required the hyperbolic logarithms of 327 and of .00142. The common logarithm of 327 is 2.5145478.

2.		4.60517019
51		1.17431839
45		1036163
47		10822
80		184
Hyp. log. 327		5.78996027

The answer can be depended on to about a unit in the seventh decimal place, and 5.7899602 is the answer to seven places.

Again, the common logarithm of .00142 is 3.1522883

-3.		-6.90775528
15		34538776
22		506568
88		20262
30		69
		-6.55709853

Subtract

Hence the hyperbolic logarithm of .00142 is -6.5570985.

LOGARITHMS, USE OF. We have thought it advisable to add to this work directions on the method of using logarithms, independent of all considerations connected with the meaning and theory of these numbers. Thus a person who has a table of logarithms, and finds its preliminary explanations not sufficiently clear or complete, may possibly receive help from this article, which is not written to accompany any system of tables in particular. There are many reasons against our inserting the table of logarithms itself in a large work of reference, as was frequently done a century ago: we are pretty certain that it would not be used.

1. The object of logarithms is the performance of the second and

third operations in the following ascending scales by means of the more easy one which precedes it, aided by consultation of tables:—

Addition, Subtraction,	Multiplication, Division,	Raising of Powers, Extraction of Roots.
---------------------------	------------------------------	--

Thus multiplication is reduced to addition, raising of powers to multiplication, division to subtraction, extraction of roots to division.

2. The sum of the logarithms of two numbers gives the logarithm of their product, the difference of two logarithms gives the logarithm of the quotient, and so on. These rules are best expressed in symbols, thus:

$$\log A + \log B = \log (A \times B)$$

$$\log A - \log B = \log \left(A \div B \text{ or } \frac{A}{B} \right)$$

$$\log (A^m) = m \times \log A$$

$$\log (\sqrt[m]{A}) = \log A \div m.$$

3. The logarithms wanted are taken partly from a table, partly from an easily remembered rule. The integer part of the logarithm is found by the rule; the fractional part by the table.

4. The integer portion of the logarithm is called the *characteristic* of the number: thus 2167.3 has 3.33592 for its logarithm, and 3 is the characteristic of 2167.3. It is very common to call this 3 the characteristic of the logarithm itself; but it is better to fix this appellation upon it in connection with the number from which it arises.

5. The characteristic of a number depends entirely upon the place which the decimal point occupies. But the rest, or fractional part, of the logarithm of that number depends upon the significant figures only of the number, and has no connection with the meaning which those figures gain by their position relatively to the decimal point. Thus .21673, 21.673, .00021673, 21673, 21673000, &c., are numbers with different characteristics, or different integer portions in their logarithms. But the fractional portions are the same in the logarithms of all, namely, .33592.

6. The characteristic of a number may be either *positive* or *negative*. For our present purpose, it will be sufficient to lay down the rules for using these quantities, directing the reader who is not used to the distinction to try to explain them by considering positive quantities as gains, negative quantities as losses, addition as junction, subtraction as removal. Thus the addition of a positive quantity (annexation of a gain) is the same thing as the subtraction of a negative quantity (removal of a loss); and so on. The following examples will illustrate this; the negative quantity being distinguished from the positive one by a bar drawn above it:—

8 and $\bar{5}$ make 3.	$\bar{2}$ from $\bar{3}$ gives $\bar{1}$.
8 and $\bar{11}$ „ $\bar{3}$.	$\bar{2}$ from $3 \dots 5$.
2 and $\bar{7}$ „ $\bar{9}$.	3 from $\bar{2} \dots \bar{5}$.
4 times $\bar{6}$ is $\bar{24}$;	$\bar{3}$ from $\bar{2} \dots 1$.
if we carry 3, it gives $\bar{21}$.	$\bar{8}$ from $\bar{3} \dots 5$.

7. The rule for finding the characteristic is as follows. When there are significant figures before the decimal point, the characteristic is one less than the number of them. But when the significant figures begin after the decimal point, the characteristic must be marked negative, and must point out the place in which significance begins.

Thus the characteristic of 2791.68 is 3; that of 17462 is 4; that of 29.137 is 1; that of 9.999 is 0; that of .763 is $\bar{1}$; that of .0198 is $\bar{2}$; that of .000072 is $\bar{5}$.

8. It is worth while to remark that this broken rule, as it seems to be, requires subdivision only on account of the notions generally attached to the *decimal point*, which is treated as if it were one of the places of the number. But if the decimal point were, as it ought to be, considered as part and parcel of the *unit's place*, so that 12.34, for instance, is not $|1|2| \cdot |3|4|$, but $|1|2|3|4|$, then the two rules might be given under one, as follows. The characteristic of a number is the number of places by which the first significant figure is distant from the unit's place; and is positive when that first figure falls to the left, negative when to the right. Thus in 1234.567 or 123 (4) 567 it is 3; in .00029 or (0) 00029 it is $\bar{4}$.

9. A mixed number, such as $\bar{3}.92741$, is thus multiplied and divided:

$$\begin{array}{r} \bar{3}.92741 \\ 6 \\ \hline 13.56446 \end{array} \qquad \begin{array}{r} 6) \bar{3}.92741 \\ \hline \bar{1}.65457 \end{array}$$

In multiplication, the multiplication of the negative figure produces a negative result, and the carriage from the positive part goes in diminution of this number. The last step is: 6 times $\bar{3}$ is $\bar{18}$, and 5 is $\bar{13}$. In division, a divisible figure must be sought *above* the negative characteristic, not *below* it; and the units necessary to make up that divisible figure must be afterwards carried to the right in the usual way. Thus when $\bar{21}.116$ is divided by 5, the first step is: 5 is contained in $\bar{25}$, $\bar{5}$ times, carry 4; then 5 is contained in 41, 8 times, &c.

$$\begin{array}{r} 5) \bar{21}.116 \\ \hline \bar{5}.823 \end{array} \qquad \begin{array}{r} 11) \bar{8}.212 \\ \hline \bar{1}.292 \end{array} \qquad \begin{array}{r} 10) \bar{31}.606 \\ \hline \bar{4}.961 \end{array}$$

10. The decimal part of the logarithm is taken out of the tables. These are not complete logarithms, which could not be given, since the real logarithms are generally interminable decimals. The only numbers which have logarithms capable of finite expression (in the system commonly used) are those in the series0001, .001, .01, .1, 1, 10, 100, 1000, of which the complete logarithms are the characteristics themselves, or $\bar{4}$, $\bar{3}$, $\bar{2}$, $\bar{1}$, 0, 1, 2, 3, The tables give only a certain number of the first decimal places, and may be named after the number of decimals in the logarithms they give. Thus a table which gives four decimals in each logarithm may be called a four-figure table; and so on. A calculator chooses his table according to the degree of accuracy he wants: the general rule being that, so many decimals as there are in the logarithms, so many significant figures of the answer may be found correct, with perhaps an error of a unit or two in the last figure. Thus if the real answer to a question were .00123769728, we might expect from four-figure tables to get .001236, .001237, .001238, or .001239. But seven-figure tables would probably give from .001237695 to .001237699. Perhaps the liability of the last figure to error is, for the general run of questions, rather over than under stated in the above. Four figures are very often enough; five figures almost always. When five figures are not sufficient, we should recommend having recourse to seven at once, for a reason presently mentioned.

11. We insert specimens of a four-figure, five-figure, and a seven-figure table.

12. To find the logarithms of numbers and the numbers to logarithms, from the four-figure table, proceed as follows: From inspection of the number, take the proper characteristic, and then note the first four significant figures. In the row which begins with the first two, find the figures which are in the column headed by the third; and add to them the figures out of the side table which are in the column headed by the fourth. For instance, required, as well as it can be given from a four-figure table, the logarithm of 4275898.116. The characteristic is 6: and the first four significant figures are 4276 (reading 58 rather as 60 than as 50). In the row 42, and under 7, we see 6304, and in the side table opposite to 6 is 6, and 6304 + 6 is 6310. Hence 6.6310 is the logarithm of 4275898.116; so far as the four-figure table will give it. Similarly the logarithm of .4 (which must be read .400) is 1.6021, that of 430 is 2.6335, that of .04179 is 2.6210.

To find the number to a logarithm, in the four-figure table, use the decimals of the logarithm with the antilogarithmic table in the same manner as the four significant figures of the number were used in the other table to find the logarithm; and then settle the place of the decimal point by means of the integer of the logarithm. The four-figure table goes into so small a space that it is worth while to print an inverse table of antilogarithms, or of numbers to logarithms; of which table we have also given a specimen above. Thus the number to the logarithm 5.6234 being required, we neglect 5, and, going into the antitable with .6234, opposite to .62 and under 3 we find 4198, and under 4 in the side table we find 4. Hence 4198 + 4 or 4202 are the first four significant figures of the number required; and its characteristic is 5: whence 420200 is the number to the logarithm, as near as the four-figure table will give it. Similarly the number to .6111 is 4.084, that to 3.6208 is .004177, that to 9.6000 is 3981000000.

13. We give an instance of the application of each of the rules in § 2. Let it be required to find, as nearly as four-figure tables will do it, the product of 17798 and 63426; the quotient of 17.293 divided by .942942; the eighth power of 1.9273, and the eleventh root of .00005569181. The processes are as follows:—

$$\begin{array}{r} \text{Log of 17798 (say 17800)} \quad 4.2504 \\ \text{Log of 63426 (say 63430)} \quad 4.8023 \end{array} \left. \vphantom{\begin{array}{r} 4.2504 \\ 4.8023 \end{array}} \right\} \text{Add.}$$

$$\begin{array}{r} \text{Log of product} \quad 9.0527 \\ \text{Answer 1129000000 from the table.} \\ \text{True Answer 1128855948} \end{array}$$

$$\text{Error} \quad 144052, \text{ about } .0001 \text{ of the whole.}$$

$$\begin{array}{r} \text{Again, log 17.293 (say 17.29)} \quad 1.2377 \\ \text{log .942942 (.9429)} \quad 1.9745 \end{array} \left. \vphantom{\begin{array}{r} 1.2377 \\ 1.9745 \end{array}} \right\} \text{Subtract.}$$

$$\begin{array}{r} \text{Log of quotient} \quad 1.2632 \\ \text{Answer 18.33.} \end{array}$$

$$\begin{array}{r} \text{Log 1.9273 (say 1.927)} \quad 0.2849 \\ \text{Multiply by} \quad 8 \end{array}$$

$$\begin{array}{r} \text{Log of (1.927)}^8 \quad 2.2792 \\ \text{Answer 190.2.} \end{array}$$

In raising powers, the errors are generally larger than in other processes, seeing that the necessary error of the logarithm is multiplied as many times as the logarithm itself.

$$\begin{array}{r} \text{Log .00005569181 (say .00005569)} \quad 5.7458 \\ \text{Divide by 11} \quad 1.6133, \text{ log } \sqrt[11]{.00005569} \\ \text{Answer .4105.} \end{array}$$

14. Before beginning to use five-figure tables, it is advisable to practise the formation of the tenths of numbers not exceeding 50, in the head. For instance, which is the nearest integer to 7-tenths of 37. The process at length would of course be

$$\begin{array}{r} 37 \\ 7 \\ \hline 10)259 \end{array}$$

$$25.9 \text{ Nearest integer 26.}$$

It should be done thus: Having multiplied 7 by 7, and got 49, reject the units, and carry 5 as the nearest number of tens. Then add 5 to 21 obtained from the three. When 5 units are thrown away, consider the ten next above as the nearest. Thus 9-tenths of 45 should be considered as 41, not 40, and 5-tenths of 17 as 9, not 8. Similarly, 8-tenths of 21 is 17; 3-tenths of 19 is 6. But 2-tenths of 32 is 6; 7-tenths of 42 is 29; 9-tenths of 28 is 25.

15. In the specimen of the five-figure table will be seen four figures of number, followed by five figures of logarithms, and an additional column marked D, which contains nothing but the differences between the successive sets of five figures in the logarithm. This column D is referred to under the name of the column of tabular differences. To take the logarithm of a number, take the characteristic as before, and five significant figures of the number. Find out the first four significant figures in the table, and to their five figures of logarithm add as many tenths of the tabular difference as there are units in the fifth significant. Thus to find the logarithm of .011217, we find 1121 in the specimen, opposite to which is 04961, with 38 for a tabular difference. Now 7-tenths of 38 is 27, and 61 and 27 is 88; so .04988 is the decimal part of the logarithm. Similarly if the significant figures of the number be 11223, the decimals of the logarithm are .05011; also 11201 gives .04926; 11209 gives .04957; 58332 gives .76591; 58333 also gives .76591; 58334 gives .76592; and so on.

16. There is no antilogarithmic table to a five-figure table; and the way of finding the number to a logarithm is as follows: Seek out among the logarithms the decimals next under the decimals of the given logarithm, and take the four figures of number belonging to them for the first four significant figures of the number. Find by how much the decimals just used fall short of the given decimals, and call this difference the unattained part. Annex a cipher to the unattained part, and divide by the tabular difference; the digit which most nearly expresses the quotient is the fifth significant of the number. For instance, what is the number to the logarithm 3.05016. Looking into the table, we find that the next under .05016 is 04999, opposite to 1122. The unattained part is 17; the tabular difference 39; and 170 contains 39 4 times more nearly than 5 times; so that 4 is the fifth figure. The five significant figures of the number required are then 11224; and, looking at the integer part of the logarithm, the characteristic is seen to be 3; whence .0011224 is the number to the logarithm, as correctly as five-figure tables will give it.

17. The four questions worked above with four-figure logarithms are thus worked with five-figure logarithms:—

17798	4.25037	17.293	1.23787
63426	4.80227	.94294	1.97449
1128900000	9.05264	18.339	1.26338
	05231		26316
	38)330		24)220
1.9273	0.28495	.000055692, 11)	5.74580
	8	.41044	1.61325
190.37	2.27960		61321
	27944		10)40
	23)160		

18. The seven-figure tables have five figures of number, with seven decimals of logarithm; and the sixth and seventh significant figures of the number are to be provided for by means of the tabular differences. But as these tabular differences run to three and four places of figures, their tenths are written down in small separate tables. [PROPORTIONAL PARTS.] To take out a logarithm, take out the seven decimals belonging to the first five significant figures of the number, and add from the table of proportional parts the number opposite to the sixth significant, and one-tenth of that opposite to the seventh significant. Thus, to find the logarithm of 455173689, of which the first seven significant figures are 4551737, look in the table for 45517, and we have

45517	.	.	gives	6581736
Tab. Pro. P.	3	"		29
"	7	"		7
				6581772

So the logarithm required, as far as seven-figure tables will give it, is 8.6581772.

A little practice will enable the calculator to add together, without writing them down, the two contingents derived from the table of proportional parts. The computer must be careful not to miss the change of the third figure of a logarithm, which usually takes place in the middle of a line, though it can only be marked at the beginning. Thus, in the specimen the logarithm of 45603 has the decimals 6589934, but that of 45604 has 6590029, not 6580029. Some mark is usually made to give warning that the change has taken place; but those whose attention is so little alive to the circumstance as to stand much in need of this mark will often make the mistake in spite of it.

19. To take the number to a given logarithm out of seven-figure tables proceed as follows: Find the nearest decimals under the given decimals, and by subtraction find the *unattained part*. Take out the five number-figures belonging to the attained part, for the first five significant figures of the number. Look in the table of proportional parts for the nearest under the unattained part, and take the digit opposite to it for the sixth significant. Annex a cipher to the remainder of the unattained part, and take the digit opposite to the result (or its nearest) in the table of proportional parts for the seventh significant. For instance, required the number to the logarithm 1.6590176:

	6590176
45605 . .	6590125
	51
5	48
	—
3	30
Number required 45.60553.	

20. The following is the working of the four questions already worked with four-figure and five-figure tables:

17798	4.2503712
63426	4.8022673
	9.0526385
11288	0.526170
	215
5	193
6	220
Answer 1128856000.	
17.923	1.2378703
.942942	1.9744850
18.33941	1.2633853
1.9273	0.2849493
	8
190.3682	2.2795944
00005569181	11)5.7457913
.4104439	1.6182538

21. More complicated questions may be *directly* solved by logarithms, that is, without requiring to seek the number to a logarithm until the end of the process, so long as the multiplications, divisions, involutions, and evolutions are not broken by additions or subtractions. Thus to calculate $\sqrt[4]{a^2 b^3 c \div d}$ we form for the logarithm of the answer

$$\frac{1}{11} \{ 2 \log a + \log b + \frac{3}{2} \log c - \log d \}$$

But if additions or subtractions intervene, the process must be broken to produce the result; that is, the logarithmic process must be suspended, and the results exhibited in numbers for the performance of the additions and subtractions (unless indeed Gauss's logarithms be employed). [LOGARITHMS, GAUSS'S.] Thus to find $\sqrt{(a^2 b + cd)}$, it would be necessary, not merely to form the logarithms of $a^2 b$ and cd , or $2 \log a + \log b$ and $\log c + \log d$, but to find the numbers to them: these numbers being then added, and the logarithm of the sum being taken, half the last logarithm is the logarithm of the answer.

22. There is nothing in the trigonometrical logarithms more than is described in TRIGONOMETRICAL TABLES. Many young students, from seldom or never using the actual sines, cosines, &c., of angles, but only their logarithms, are apt to confound the former with the latter.

23. Some little additional correctness may be obtained by annexing to the use of the tables, as given above, an attempt to add something for one more figure of the number. Thus, suppose it required to find the logarithm of 11.374928. In the four-figure table 113 has 0531 and ... 7 adds 26. The next figure is 4, which, had it been the fourth significant, would have added 15; being the fifth, let it add the tenth of 15, or its nearest integer, 2. Hence we add 28 instead of 26 to

0531, and get 0559 instead of 0557, as a nearer approach to the logarithm. Again, in the five-figure table, 1137 gives 05576, and the tabular difference is 38. The 4 gives 15, or 4-tenths of 38, and the 9 ought to give 9-hundredths of 38, or 3. Consequently 15 + 3, or 18, is added, giving 05594. Had 49 been read as 50, in the usual way, 19 would have been added. In the seven-figure tables 11374 gives 0559132; 9 adds 345, the 2 should add the tenth of 77, and the 8 should add the hundredth of 306: hence 3 more should be added than arises from the figures 92. This plan may be followed when the greatest accuracy is desirable, especially in the four-figure table. It is most useful when the tabular differences are large, that is, at the beginning of the table.

24. It may sometimes save a mistake if the computer remember that the significant figures of the number generally read less than those of the decimals in the logarithm. Thus 200... has 301... for the decimal figures of the logarithm. It is not so however at the beginning of the table, and the figures of the logarithm overtake those of the number between 13712 and 13713.

25. The rule of the characteristics, when well learnt, furnishes one of the easiest modes of assigning the place of a decimal point in a common division. For example, in dividing .0017643 by .018416, the characteristics being $\bar{3}$ and $\bar{2}$, we shall have to carry 1 to $\bar{2}$, because significant figures of the divisor, 18, are greater than those of the dividend, 17. Take 1 then from $\bar{3}$, which leaves $\bar{2}$, the characteristic of the quotient, which has therefore .0 before its significant figures. The rule is, to find the characteristic of the quotient, from that of the dividend subtract that of the divisor, carrying 1 if the first significant figures of the divisor be greater than those of the dividend.

26. In using the trigonometrical tables, or any other, careful attention must be paid to the right choice of the method of interpolation. If the argument and tabular result [TABLE], or the numbers with which we enter the table and those which we take from it, increase together or diminish together, then the alterations introduced by the table of proportional parts consist in adding to either for every addition to the other, and subtracting for every subtraction. But if the tabular result diminish as the argument increases, then every addition to the one is accompanied by a subtraction from the other, and *vice versa*. In the tables of logarithmic cosines and cotangents, the young computer frequently falls into error from neglect of the last-mentioned direction. Thus the logarithm of the cosine of $84^\circ 9'$ in a five-figure table is 9.00828, and the tabular difference is 124, diminishing. Hence the log cosine of $84^\circ 9' 5$ is not $9.00828 + .00062$, but $9.00828 - .00062$. And if we ask for the angle whose log cosine is 9.00840, we find the next underneath this in the table to be 9.00828, and 22 for the unattained part. Divide 220 by 124, and 2 is the nearest integer. But the angle required is not $84^\circ 9' + 0.2$, but $84^\circ 9' - 0.2$, or $84^\circ 8.8$.

27. The equation $a^x = b$, in which x is unknown, is solved by taking the logarithm of both sides, which gives $x \log a = \log b$, or $x = \log b \div \log a$. The process may perplex a beginner when the logarithms have negative integers. We therefore subjoin an example. Let it be required to solve the equations

$$\left(\frac{4}{7}\right)^x = .00163 \text{ and } 182^y = .6.$$

(The reader is supposed to know the complete interpretation of algebraical exponents.) We have then

$$x = \log(.00163) \div \log\left(\frac{4}{7}\right) = \bar{3}.21219 \div \bar{1}.75696$$

$$y = \log .6 \div \log 182 = \bar{1}.77815 \div 2.26007.$$

Now throw the three logarithms which have negative integers into the more usual algebraical forms.

$$\begin{array}{lll} .21219 - 3, & .75696 - 1, & .77815 - 1 \\ \text{Or } -2.78781, & - .24304, & - .22185 \end{array}$$

And make the divisions, which give for the quotients 11.471, and -.098161; or

$$\left(\frac{4}{7}\right)^{11.471} = .00163, \quad (182)^{-.098161} = .6$$

LOGIC. Since the 'Penny Cyclopædia' was completed, the study of logic in this country has undergone three important changes. First, much more attention is paid to the subject: secondly, innovations have been listened to in a spirit which seems to admit that Kant's dictum about the perfection of the Aristotelian logic may possibly be false: thirdly, a disposition has arisen to distinguish logic from metaphysics and psychology, without losing sight of the psychological and metaphysical discussion which is necessary to a sound view of the meaning, province, and first principles of the science. In such a state of transition the best thing to be done is to allow the main logical articles of the 'Penny Cyclopædia' to stand unaltered, as representatives of a starting point, and to devote the present article chiefly to some account of recent developments and current disputes. We therefore refer to ORGANON, SYLLOGISM, &c., as preparatory to the present article.

We also explain that we are not writing for (nor against) the competent disputant, but for the learner who has mastered the common elements; that we refer to England (meaning the three kingdoms) and English thought only; and that we treat of that part of logic which may be styled an exact science, without any discussion of the grounds on which its obvious postulates are founded.

The changes to which we have alluded arise from that revival of the taste for philosophy which has commenced and is continuing, both in England and France. So far as England is concerned this revival was preceded by the publication of Dr. Whately's work, the first edition of which was an article in the *Encyclopædia Metropolitana* (about 1826). The author had for years taught the subject at Oxford, and had trained some, at least, to see the low state into which logic had fallen; a state not exaggerated in the unfriendly criticism presently mentioned. This work placed logic, in a comparatively attractive form, within the reach of many out of Oxford, to whom all the attainable books had been sealed by the stamp of a current prejudice; and it had merits of its own. The Archbishop of Dublin possesses the talent which distinguished Paley from his predecessors; the talent of rendering a dry subject attractive in a sound form by style, illustration, and clearness combined. And to him is due the title of the restorer of logical study in England.

In 1836, ten years after the publication of Dr. Whately's work, Sir William Hamilton [BROG. DIV.] was appointed professor of logic and metaphysics in the University of Edinburgh. The extraordinary character of his learning is not overrated in the article cited. But it should be added, as necessary to be known by any one who enters on the logical controversies of the day, that his strange hatred of the mathematical sciences was owing to an unusual inaptitude for them, which prevented, probably any sufficient study, certainly any real understanding, even of their lowest branches. In 1829, he commenced that powerful series of articles in the '*Edinburgh Review*' by which his reputation was first established out of Edinburgh: these were republished with some additional notes, under the title of '*Discussions in Philosophy*'; and no higher logical student can dispense with them. In 1833 appeared the celebrated criticism on Dr. Whately's *Logic*, of which the first thing to be said is that it is due to Dr. Whately himself that it had an audience to listen to it: its history, philosophy, and philology, would have fallen dead upon the previous generation. Accordingly this criticism, though most valuable as a logical dissertation, and of a necessity to be read which does not lessen with time, is nothing as a criticism; for it neither is nor proceeds upon a true view of the place and office of the work criticised. Nevertheless, it was one of the stimulants of the revival.

The meaning of the word *logic* has undergone much variation in different hands. It has been what the writer pleases, from the whole of the inquiry into truth and falsehood down to the investigation of the Aristotelian syllogism. This diversity of signification is probably near its end. There is a growing disposition to admit Kant's definition, which describes it as the science of the *necessary laws of thought*: it is said to treat of the *form* of thought independently of its *matter*. Though neither Aristotle nor his followers confine themselves within this definition, nor even so much as distinctly conceive it, all will acknowledge that the definition singles out the most important distinctive feature of their system. A few words on the relation of *form* and *matter* will be requisite.

When many things are thought of in one way, which way is neither governed nor modified by the difference between one thing and another, there is a common *form* of thought about distinct *matters*. Thus arithmetic is a formal science with reference to concrete magnitude: that 8 and 4 make the same as 4 and 8 is a form, a law of thought, which is not affected by the objects counted being yards rather than sheep, or pints rather than men. Pass into algebra, and the difference which are formal in arithmetic become only material: thus $8 + 4 = 4 + 8$ is but one material instance of the form $a + b = b + a$. Are we therefore to say that arithmetic and algebra are parts of logic? Certainly not: logic deals with the pure form of thought, divested of every possible distinction of matter. There is a form of thought in the above which is not even confined to number, and not even confined to magnitude: namely, that the manner in which we think of *part* and *whole*, in every possible case in which these words can apply, is wholly independent of the order in which the parts are considered as coming together. For example, the notions *animal* and *rational* are joined together in the mind when we think of *man*, but by a mode of junction very different from that called addition in arithmetic. Nevertheless, it matters nothing as to the notion arrived at whether we think of *animal* as subsequently limited by the notion *rational*, or of *rational* as subsequently limited by the notion *animal*. The pure form of thought is that which belongs equally to the last instance and to $8 + 4 = 4 + 8$; different matters, different modes of junction, under the common law that order of junction is indifferent.

We now set down the titles of various works of recent publication, and not difficult to obtain, being works which may all be recommended to the student who wishes to go fully into existing controversies, both as sources in themselves and as guides to others.

Paris, 1839-44, 4 vols. 8vo: Barthélemy St. Hilaire, '*Logique d'Aristote*,' a translation of the '*Organon*' of Aristotle, with notes. Paris, 1838, 2 vols. 8vo: Barthélemy St. Hilaire, '*De la Logique*

d'Aristote,' a description of the '*Organon*' which gained the prize of the Institute. London, 1853, 2 vols. 8vo: O. F. Owen, '*The Organon of Aristotle*,' an English translation. London, 1857, 8vo: J. H. M'Mahon, '*The Metaphysics of Aristotle*,' an English translation. Berlin, 1842, 8vo: F. A. Trendelenberg, '*Elementa Logices Aristotelicæ*,' extracts from Aristotle, translated in the article *ORGANON*, and notes. Edinburgh, 1854, 12mo: T. S. Baynes, '*The Port Royal Logic*,' a translation from the French, with notes. Paris, 1840, 8vo: J. Tissot, '*Logique de E. Kant*,' a translation highly spoken of. There is an English translation of Kant's *Logic*, not easily got, by T. Richardson, London, 1819, 8vo, collected with some other translations from Kant, under a title-page of 1836. London, 1851, 2 vols. 8vo (3rd edition, one or more since): John S. Mill, '*System of Logic, ratiocinative and inductive, being a connected view of the principles of evidence and the methods of scientific investigation*,' a great and widely known work, which takes logic in the fullest extent of meaning: we think Mr. Mill would have done more justice to himself, and given a better notion of his subject, if he had taken a more descriptive title; the words which follow "*Logic*" are of no use, for the book will be "*Mill's Logic*" all the world over. With this work, and in reference to a large part of its contents, may be read Dr. Whewell's writings on philosophical method and history, especially London, 1858, 8vo, '*Novum Organum Renovatum*,' and London, 1860, 8vo, '*The Philosophy of Discovery*.' The '*Novum Organum*' of Bacon himself, not to speak of the recent edition (Longman) of Leslie Ellis and others, which is a magnificent performance, may be easily and cheaply obtained in—London, 1853, 8vo, J. Devey, '*The Physical and Metaphysical Works of Lord Bacon*,' Edinburgh, 1850, 8vo: T. S. Baynes, '*The New Analytic of Logical Forms*,' a prize essay, the first treatise on Sir W. Hamilton's system, with a note by Hamilton himself. London, 1853, 8vo, 2nd edition: Wm. Hamilton, '*Discussions on Philosophy, &c.*,' already mentioned. There is a writing of Sir W. Hamilton which, from its ephemeral character, may be forgotten, but which is very characteristic of the author, and contains logical discussion of permanent value; London and Edinburgh, 1847, 8vo: 'A Letter to A. De Morgan, Esq., on his claim* to an independent re-discovery of a new Principle in the Theory of Syllogism.' The prospectus of Hamilton's work on logic, which he did not live to complete, attached to this writing and to others, should not be forgotten. Edinburgh, 1858, 8vo: A. C. Fraser, '*Rational Philosophy in History and in System*,' the programme of Sir W. Hamilton's successor, who was further known by—Edinburgh, 1856, 8vo, '*Essays in Philosophy*,' a collection of reviews on philosophical subjects, from the '*North British Review*.'

Of Whately's *Logic*, already mentioned, there are many editions; and the same of Dr. Watts's *Logic*, an old and well-known work, which deserved much higher praise than it received.

Oxford, 1856, 8vo, 3rd edition: H. L. Mansel, '*Artis Logicæ Rudimenta*,' an edition of the old and celebrated compendium of Aldrich, with copious English notes; the easiest and best way in which a body of discussion on the old logic can be read. Oxford, 1851, 8vo: H. L. Mansel, '*Prolegomena Logica*,' an inquiry into the psychological character of logical processes, a most acute work, opposed to all the views of this article. The same writer's article on *Metaphysics* in the new edition of the *Encyclopædia Britannica* (vol. xiv., 1857) will be very useful in conjunction with the '*Prolegomena*.' London, 1857, 8vo: W. Thomson, '*An Outline of the Necessary Laws of Thought*,' a treatise on pure and applied logic; valuable by thought, brevity, eclectic character, and extent of plan. Oxford, 1850, 8vo: E. Poste, '*The Logic of Science*,' a translation of the *Posterior Analytics* of Aristotle, with notes. Oxford, 1848, 8vo: C. P. Chretien, '*An Essay on Logical Method*.' Oxford, 1851, 2 vols. (or books) 8vo: W. H. Karlake, '*Aids to the Study of Logic*.' These works are all highly and justly commended by Sir W. Hamilton.

Edinburgh, 1857, 8vo: W. Spalding, '*Introduction to Logical Science*' (reprint from the *Encyclopædia Britannica*), a thoughtful work, of much collection and discussion as to recently disputed points. London, 1856, 12mo: R. G. Latham, '*Logic in its Application to Language*,' a grammatical application well worthy the attention of teachers.

Of writers who have called in mathematical principles and forms, we have the following works:—London, 1847, 8vo: A. De Morgan, † '*Formal Logic, or the Calculus of Inference, necessary and probable*.' London, 1860, 8vo: A. De Morgan, '*Syllabus of a Proposed System of Logic*.' This syllabus contains references to the author's papers in the *Cambridge Transactions*, in which most of his novelties were first broached. Cambridge, 1847, 8vo: G. Boole, '*Mathematical Analysis of Logic*.' London, 1854, 8vo: G. Boole, '*Investigation of the Laws of Thought*.'

There is an immense collection published, and publishing in France, under the name of '*Cours de la Patrologie*,' by the Abbé Migne. This collection contains many writers whom the logician desires to have, but can rarely obtain: as Boethius, Abelard, Peter Lombard, John of

* The reply which closed this controversy—all subsequent feud being on new grounds—is in the first Appendix to Mr. De Morgan's '*Formal Logic*,' presently described.

† When controversial points are treated as in the present article, it is not fair that one of the parties to the disputes should take the appearance of an indifferent judge by writing anonymously. This note is therefore added to the name of the writer of this article.

Salisbury, &c., &c., and a dictionary of scholastic philosophy and theology. It is to be wished that the publisher should circulate in England a distinct prospectus of the writers whose logical works have been reprinted; and it may be added, that a small addition to the bulk of the whole work would make its mediæval logic nearly as complete as its theology. The volumes are sold separately, and are very cheap.

It is impossible to give any account of the history of the subject which was first analysed by Aristotle, and afterwards received from Zeno the Stoic, as is supposed, the name of *logic*. That history is not yet written in full. A history of one logical idea, that of the CATEGORIES, was published by Trendelenberg a few years since; and recently, as we are told, the first volume of a professed history of the whole subject has been published in Germany by Prantl, which comes down as far as Boethius inclusive. A sketch of leading points and names is given by Mr. Mansel, in the introduction to his edition of Aldrich, dwelling briefly on the connection with logic of Zeno the Eleatic, the sophists before Aristotle, Socrates, Plato, Aristotle, Theophrastus, Eudemos, Zeno and other Stoics, the Epicureans, Alexander of Aphrodisias, Ammonius, Simplicius, Philoponus, Porphyry, John of Damascus, Photius, Psellus, Blemmidas, Pachymeres, Leo Magentinus, George of Trebizond, Cicero, Apuleius, Augustine, Marcellinus Capella, Boethius, Cassiodorus, Avicenna, Averroes, Abelard, Gilbert Porretanus, John of Salisbury, Peter Hispanus, Albertus Magnus, Thomas Aquinas, Duns Scotus, Occam, Raymond Lully, Buridan, Burley, Laurentius Valla, Rodolphus Agricola, Ludovicus Vives, Peter Ramus, Melancthon, Burgersdicius, Keckermann, Downname, Milton, Bacon, Descartes, Locke, Leibnitz, Hobbes, Gassendi, Clauberg, Arnauld and Nicole, Buffier, Le Clerc, Watts, Wolff, Baumgarten, Lambert, Ploucquet, Kant. So bare are the books of logic of all account of its history, that a mere list of the names which would be most prominent in such a history, by which the student may resort to biographical dictionaries or general histories of philosophy, is a valuable addition to such an article as the present.

The great points of elementary logical investigation are four in number: 1. The *name* or *term*, the representative of one object of thought, as distinguished from others, including a mode of thinking. 2. The *relation*, or mode of bringing two terms together, signified by a *copula* connecting two terms. 3. The *proposition* or *judgment*, a relation between two terms affirmed or denied. 4. The *sylogism*, deduction of a relation between two terms by means of the relations of the two to a third term. These points must needs include the consideration of all the laws of ratiocinative thought in action: surely, What? What else? What of them? and What then? are questions which point to all that can take place in a mental process by which thought leads to thought. Nevertheless, by certain restrictions which we hold to be purely arbitrary, logicians have curtailed their science, and made it appear to contain but a very small part of the processes of actual thought. In placing before the student a mere sketch of disputed points, we remind him that many things must be left unstated, many objections unprovided for. He must look for full assurance, either for or against, in writings of more extended character, and in discussions which are fully guarded by the use of defined technicalities.

First, as to the term or name, which may be in one word or in many. The old logicians drew the distinction between a name used as simply denoting an external object, such as might be thought of as existing without any mind to think of it, and the name used as thinking of the object in its mental relation to other objects. A *man*, thought of as an individual pointed out, or a quality, as *white*, the white of a particular white ball, were called names of *first intention*, or *first notions*. But *man* as a class, or an individual thought of as a member of a class, and *white*, as an attribute of classes, were names of *second intention*, or *second notions*. The distinction is precisely that now known as objective and subjective: and accordingly, we propose to consider things—not material things only—and the qualities residing in them, as belonging to the objective use of names; and classes, and the attributes by which we define classes, as belonging to the subjective use. Now though the logicians have always professed to cultivate second intentions, or subjective uses, the forms and the language of the syllogism have been strictly fashioned on the objective use, and allowed to remain so.

Next, it is clear that a name excludes as well as includes: every object of thought is related to *man*, for instance, either as *in* the name or *out*. The logician has always excluded the privative name, *not-man*, for instance, as all but useless: a certain practice of his own really makes it so. For he will have no *universe*—or total sphere of thought—except the whole universe of possible existence; or, at narrowest, the whole universe of objective reality. He forgets that, more often than not, the universe of the existing topic of thought is limited. We are talking of animals, for example, and nothing else: *not-man* becomes so definitely significative that we have a separate name for it, *brute*. Logic ought to give us that command of thought which will prevent our mental vision from being obstructed by the casual absence of a name; and it ought to investigate the *actual* form of thought, as well as possible scientific generalisation.

Thirdly, two names may be joined either as separate parts of a common whole, or as jointly separating the common part of two

different wholes. Thus the class *animal* has the two separate sub-classes, *man* and *brute*: but *man*, under the name *rational animal*, is seen as belonging to the common part of the two wholes, *rational being* and *animal being*. We call the first procedure *aggregation*, the second *composition*. The first process is *mathematical*: *animal* is made up of *man* and *brute* after the same law of thought by which a square is made up of two triangles. The second process is deep in the nature of things, *metaphysical*: the combination of *rational* and *animal* into a being such as *man* is not conceivable as *aggregation* or *addition*, and no more. Nevertheless the logician does not admit this: he announces an object as the *sum* of all its attributes. The preceding distinction divides logic into two parts, which we call the mathematical and the metaphysical; not meaning that one part of logic is mathematics, and another metaphysics, but that the distinctive features of the two sides of logic are of prominent account, the one in mathematics, and the other in metaphysics.

The distinction of composition and aggregation was conveyed and implied in a few remarkable words of Aristotle, contained in his *Metaphysics*: "The genus is said to be part of the species; but in another point of view the species is part of the genus." *Animal* is part of *man*: the *whole* notion (all the attributes) of *animal* forms part (component) of the notion *man*. But *man* is part of *animal*: the *whole* class (all the individuals) of *man* form part (aggregant) of the class *animal*. This is the heading of a chapter in logic which only begins to be written in full in our own day: the logicians always threw the idea of attributes compounded of attributes into metaphysics, and retained the mathematical notion of class aggregated of classes for logic. The attributes which compound into an attribute were said to form its *intension*: the classes which aggregate into a class were said to form its *extension*. This distinction of extension and intension—or extent and intent—is now often styled that of extension and comprehension; the Mills, father and son, call it that of denotation and connotation; Hamilton, that of breadth and depth. The revival of the distinction, in logic, and as a separation of the two sides of logic, is mainly due to Hamilton: but he and his followers have made a singular misconception. In the above explanation it appears clearly that the logical *quantities* change terms in the opposed modes of speaking. *All animal* (all the attributes) forms *part* of the notion *man*: *all man* (the whole of the class) forms *part* of the class *animal*. According to Hamilton, the quantities do not change places. He affirms that when we say "All men are some animals," we speak * in depth; and that when we say "Some animals are all men" we speak in breadth. We shall not enlarge upon this distinction: we do not think it necessary to impress at length upon the reader that Hamilton's distinction is not the great distinction of the laws of thought. And such discussion would be the more inappropriate at this time, because Hamilton's logical lectures are on the eve of publication by Mr. Mansel, who may be expected to defend his principal well, if defence be possible, and who must either defend or surrender. And we are glad of the opportunity of calling the reader's anticipation to a work which will most surely contain a vast breadth and depth of thought.

Lastly, every logical term is postulated as having existence in thought, or existence in external reality, according to the universe in question. It is only as representing existence that a term is used in logic. Thus, when from every *x* is *y*, and every *y* is *z*, we infer every *x* is *z*, our premises are supposed to imply the assertions that *x*, *y*, *z* exist.

We now come to the *copula* or relation by which terms are connected, and the *proposition* or *judgment*, which asserts or denies the connection. And here the logicians admit only one copula into the form of the proposition: that is, *identification*, affirmed by *is*, denied by *is not*. If we say *A* goes before *B*, they call this proposition a material connection between *A* and *B*. They hold that the form of the above which is essential to its consideration in pure logic is "*A* is a thing which goes before *B*." And they further maintain that there are three fundamental forms of thought, which they call the principles of *identity*, *difference*, and *excluded middle*. Of identity, *A* is *A*; of difference, *A* is not *not-A* (or *B*, other than *A*); of excluded middle (or of *nothing between*), *B* is either *A* or *not-A*. That every thought of our minds must be fashioned so as not to contradict either of these principles is most evident; as evident as the things themselves; as sure as eggs are eggs. But the logician assumes a right to say that only these propositions are of the pure form of thought, true by the form: and that all others are true by the matter and not by the form. Because all assertion identifies something with something, and all denial separates something from something, he lays it down that identity and difference constitute the only forms of comparison of ideas, or the whole form. For ourselves, we believe that there is matter in the proposition "*A* is *A*," one specific relation, identity: we do not see why, except by arbitrary separation founded upon great importance, the process of identification and the relation of identity

* Mr. Mansel (*North Brit. Rev.*, May, 1851), inverts this mode of reading. He will have 'some *A* is all *B*' to mean that all the attributes of the concept *B* are some of the attributes of the concept *A*; and 'all *B* is some *A*' to mean that all the things possessing the mark (or name) *B* are a portion of those possessing the mark *A*. We must leave the Hamiltonian logicians to settle among themselves which is which: that is, to array the two propositions—'Some animal is all man,' and 'all man is some animal'—under their proper banners.

are declared to be of so different a nature from all other processes and relations as to make the difference of form and matter. To us the pure form of the proposition, divested of all matter, is the assertion or denial of the following:— x stands in relation L to y . The proposition " x is x " is brought under the general form by two introductions of matter: L is identity, and x and y are the same symbols.

What is the test of distinction between a consequence which is true by its form, and one which is only true by its matter? When the assertion is true by its form, it can only be refused admission by impossibility in its matter; and when it can only be refused admission by impossibility in its matter, it is true by its form: and by impossibility we mean incompatibility with the conditions of the universe understood. If the universe be the whole sphere of possible thought, the impossible is that which contradicts itself, and nothing else; a five-footed quadruped, for example. But if it be the terrestrial sphere of actual existence, the impossible is only the non-existent on earth; a rational quadruped, for example. If the universe be limited to the idea of animal, a stone is an impossibility. For instance, " A is A ," and " A is not not- A ," are true by form, in our view; how can they be denied? or rather, when can we doubt of admitting them? for assertion must be opposed to non-assertion, not to denial. Only when A contradicts itself. A horse which is not a horse, and a cow which is not a cow, are they the same things, or different? and must they be either one or the other? We leave the logicians to settle it; for ourselves we cannot tell: we do not see how to affirm, and we do not see how to deny. But we do see that " A is A " can only be questioned, whatever the result may be, when the matter of A is impossible; and we recognise it as therefore true in form.

Again, let x be an existing animal; it follows that the tail of x is the tail of an animal. Is this consequence formal or material? Formal, because this is true whatever a tail may be, so long as there is a tail; and it cannot be refused assertion except when x has no tail. A guinea-pig, for instance, puts this proposition out of the pale of assertion, and equally out of that of denial; the tail of a non-tailed animal is beyond us. There are those who will assert that the tail of a non-tailed animal is *no tail*; but we are satisfied that the tail of a non-tailed animal is just as much a *tail* as no-tail; and therein lies the contradiction and the impossibility. If we were clear that the tail of a non-tailed animal is no tail, we should know how to think of it; for we can think of every subject which comes under a predicate. This very guinea-pig is here produced by us because it has been brought forward by an acute thinker to prove that the consequence above given is *material*, and *not formal*. It has been made to prove that ' x is an animal, therefore the tail of x is the tail of an animal' is a special inference gained from our material knowledge of the thing thought about, and not a general inference necessitated by the universal laws of thinking. We answer that though the lack of tail in a guinea-pig is not a law of logic, but a material incident of the object, yet we know the *consequence* to be necessitated by the laws of thinking, because we must go to impossible matter, we must make the tail of x a non-existence, before we can refuse to assert it.

The establishment of ordinary syllogism requires two principles. First, the *convertibility* of the terms of a proposition: " A is B " gives " B is A ." Secondly, the *transitivity* of the connecting relation: " A is B " and " B is C " gives " A is C ." The logicians affirm that the three principles of identity, difference, and excluded middle, are sufficient for the evolution of all the laws of syllogism. We are not aware that any one has ever made this good by actually deducing the two principles last named from the higher three. This must be done, if at all, without syllogism, for syllogism must not be taken for granted as a step towards its own establishment; and if, as we believe, it cannot be done, then the three principles do not possess that dominant and all-sufficient character which has been claimed for them.

The syllogism is the determination of the relation which exists between two objects of thought by means of the relation in which each of them stands to some third object, which is the *middle term*. In our view of the subject the pure form of the syllogism, when its premises are absolutely asserted, is as follows:— x is in the relation L to y ; y is in the relation M to z ; therefore x is in the relation " L of M ," compounded of L and M , to z . In ordinary logic, which admits only the relation of identity, the actual composition of the relation is made by our consciousness of its *transitive* character. Thus x is y and y is z , tell us that x is that which is z . But an identical of an identical is an identical; whence x is z . Again, x is y and y is not z ; here x is that which is not- z : or x is not z . The full syllogism is a collection of such singular cases: thus every x is y , and no y is z , repeats " x is a y , that y is a not- z ," as often as there are x s in existence, and gives " $every x$ is not- z ," or no x is z .

The requisites of the copular relation, in the system of ordinary syllogism, are *transitivity* and *convertibility*. Any relation which possesses these qualities may take the place of " is " in the common syllogism, without impeachment of its validity. Thus the word "*fellow*" may have transitive senses, and is always convertible: choose a transitive signification, under which we may say that when x is a fellow of y , and y of z , then x is a fellow of z . Take a common syllogism, such as—no y is any z , some y s are x s; whence some x s are not any z s. For " is " read " $is a fellow of$," and for " $is not$ " read " $is not a fellow of$;" the inference remains valid. Against admitting this

extension it is argued that the inference is one of matter, not of form; but though every *instance* is material, or has its own matter, we maintain that the above inference depends for its validity only on those qualities which must be seen in *identity* before the *common syllogism* can be established.

The logicians are well aware that there are many copulæ which give inference by comparison with a middle term, and which are not what they call syllogisms; for instance, " A equals B , B equals C , therefore A equals C ." They reduce such arguments to syllogism by stating the requisite combination of relation in a major premise, and affirming the case to come under the combination in a minor premise. As in " $An equal of an equal of C is an equal of C ; A is an equal of an equal of C ; whence A is an equal of C ." But A and C are really compared in the mind with a middle term B , and thence with one another. When $A=B$, $B=C$, are made to give $A=C$, the process of the human mind is guided by steps in which $=$ is as truly a *copula*, or connecting relation, as " is " in " A is B , B is C , whence A is C ." The *transitive* character of the copula is as much the dictator of the result in the first case as in the second.$

Dismissing, for further consideration in *RELATION*, the extension to wider relations than those contained under " is ," we shall proceed to point out the questions which have arisen as to the common forms of enunciation, and the systems of enunciation and of syllogism which have been proposed. After a few words on the common system, we shall notice the different proposals of Mr. Boole, Sir Wm. Hamilton, and Mr. De Morgan.

The common proposition is derived from the notion of assertion or denial, applied to *all* or to *some*, giving the universal affirmative and negative, every x is y , no x is y ; and the particular affirmative and negative, some x s are y s, some x s are not y s. [SYLLOGISM.] Here *some*, as in all logical writings, means no more than *not-none*, one at least, many it may be, even all, possibly. When we say that some x 's are not y s, we only mean to deny that the class x is entirely included in the class y ; the exclusion may be partial or may be total. The logical opposition of quantity, then, is not that of whole and not-whole or part; but of quantity asserted to be the whole, and quantity not asserted to be the whole.

The old writers on logic hardly speak of universal and particular terms; they apply these adjectives to the *propositions*. They say that a *proposition* is made universal by prefixing the word *omnis* to the *subject*. Later writers *quantify* both subject and predicate. They find out that " $all x$ s are y s" means that " $all x$ s are some y s;" that " $no x$ is y " means that " $every x$ is no one of all the y s;" that " $some x$ s are y s" is " $some x$ s are some y s;" and that " $some x$ s are not y s" is " $some x$ s are not any of all the y s." And hence the well-known rule that while the quantity of the subject is indicated, the quantity of the predicate is determined by the quality of the proposition; particular in affirmatives, universal in negatives. But conversion of term and quantity is not allowed: " $all x$ s are some y s" is never seen as " $some y$ s are all x s." The usual forms of language are made to dictate restrictions to thought. We shall presently return to this point.

Mr. Boole's generalisation of the forms of logic is by far the boldest and most original of those of which we have to treat. It cannot be separated from Mathematics, since it not only demands algebra, but such taste for thought about the notation of algebra as is rarely acquired without much and deep practice. When the ideas thrown out by Mr. Boole shall have borne their full fruit, algebra, though only founded on ideas of number in the first instance, will appear like a sectional model of the whole form of thought. Its forms, considered apart from their matter, will be seen to contain all the forms of thought in general. The anti-mathematical logician says that it makes thought a branch of algebra, instead of algebra a branch of thought. It makes nothing; it *finds*: and it finds the laws of thought symbolised in the forms of algebra. [ALGEBRA, p. 199, § 9.] We cannot attempt, in this article, to do more than show, by one single case, how common algebraical operation is transformation from one logical equivalent to another. We shall choose the conversion of " $to be both not- A and not- B is impossible" into " $every thing$ is either A or B or both." Let A and B represent two objects of thought. Let 1 represent the universe, all that exists; let 0 represent the impossible, something that does not exist. Let $=$ represent identity. Let $A + B$ represent the class containing both A and B , with all the common part, if any, counted twice; let $A - B$ signify what is left of the class A , when B , which it contains, is withdrawn. Let AB represent the common part of the notions A and B . Then $1 - A$ and $1 - B$ represent all that is not A and all that is not B ; and the non-existence of everything which is both not A and not B is symbolised by$

$$(1 - A)(1 - B) = 0$$

The common rules of algebra transform this into

$$A + B - AB = 1.$$

Now, $A + B - AB$ is simply the aggregate of A and B , without repetition, the part reckoned twice in $A + B$, if any, being withdrawn once. Accordingly the second equation means that A and B between them contain the whole universe; or that everything is either A or B , or

both. We have put forward enough to enable an intelligent student to raise a string of difficulties; for the solution of most of which we must refer him to Mr. Boole's writings.

We now proceed to the discussion of Sir William Hamilton's system. At the outset the learned author puts into words a postulate* which no one would suppose had been left to him to demand. It is "that we be allowed to state in language what is contained in thought." We may trust Hamilton's learning for the fact that this postulate was never announced: but surely we shall feel inclined to ask, who has ever been timid enough not to use it, as wanted? Aristotle, we may answer, and nearly all his followers. There are cases in which Aristotle himself appears to doubt the right, or at least to waive the right, of pushing thought beyond the bounds of usual expression; and to this day logic has been circumscribed by this want of clear apprehension that language was made to express and extend thought, not to circumscribe it. The postulate ought to be pushed further; the logician ought to be allowed to state all that *can be* contained in thought; unless indeed we are to construe *is* as a junction of the present and future tenses.

Among the cases in which language did not find expression for possible thought, was the quantity of the predicate of a common proposition. The logicians, Hamilton at least, and most others we believe, affirm that thought *does* quantify the predicate; for ourselves, after much observation, we believe it does not. We believe that minds of ordinary cultivation, with whom logic has not been a study, when they have occasion to think that no quadruped is a fish, do *not* hold it in thought that they are speaking about *all* fishes, actual and possible. They may, by a process they never analysed, be able to *use* this implied truth; but we do not believe they ever held it in that way in which they hold the thought which is apt to find expression. Be this as it may, Hamilton believed, not only that a quantity is held in thought for the predicate of the ordinary proposition, but even that quantities *are* in thought which have never been expressed in language even by logicians. He accordingly applied—as had been done before him, though the results had not been worked into a logical system—both the quantities, universal and particular, to both subject and predicate. He thus put forward, as what *we have* in thought, eight forms of predication, to the statement of which we add some explanation, and some objection.

1. All *x* is all *y*. This means that *x* and *y* are coextensive terms; accordingly it is a complex† proposition, made by compounding "every *x* is *y*," and "every *y* is *x*." It is simply contradicted by the alternative of one or another of two other propositions of the system: Either "some *xs* are not *ys*" or "some *ys* are not *xs*."

2. All *x* is some *y*. This is the same as "every *x* is *y*."

3. Some *x* is all *y*. This is "every *y* is *x*."

4. Some *x* is some *y*. This is "some *xs* are *ys*."

5. Any *x* is not any *y*. In negatives, the word *any* takes the place of *all*, for the sake of grammar. We have here, "no *x* is *y*."

6. Any *x* is not some *y*. This is "some *ys* are not *xs*."

7. Some *x* is not any *y*. This is "some *xs* are not *ys*."

8. Some *x* is not some *y*. This proposition is not in ordinary use. It means that some of the *xs* are not some of the *ys*, even if they be others. To contradict it we must affirm that there is but one *x* and one *y*, and that *x* identical with the *y*. Consequently, here is a proposition which does not find its denial in the system.

Dr. Thomson ('Outlines,' &c.) admits the first seven of these propositions, but rejects the eighth: and constructs a system of syllogism accordingly.

That Hamilton really believed the above system to be in *common thought*,‡ and not the deduction of a postulated extension, is manifest.

* Besides this principle, Hamilton announced another, which had been quite as much neglected as the former: and by merely lending the weight which his acumen and learning gave him to these two fundamental requirements of logic, he will have done much to promote it, even though his practice be not quite abreast of his preaching. "Whatever is operative in thought, must be taken into account, and consequently be overtly expressible in logic; for logic must be, as to be it professes, an unexclusive reflex of thought, and not merely an arbitrary selection—a series of elegant extracts—out of the forms of thinking. Whether the form that it exhibits as legitimate be stronger or weaker, be more or less frequently applied;—that, as a material and contingent consideration, is beyond its purview."

† This is denied. But if, of propositions *A*, *B*, *C*, *A* always make *B* and *C* follow, and *B* and *C* always make *A* follow, surely *A* is identical with the junction of *B* and *C*. What does *A* contain more than is in *B* and *C* compounded? And what less? A proposition is contradicted by alternative junction of two different propositions, of which neither contains the other: is it simple or complex?

‡ He published to the world the requirements for a prize essay to be written by his pupils, among which was the following:—"The reasons why common language makes an *ellipsis* of the expressed quantity, frequently of the *subject*, and more frequently of the *predicate*, though both have always their quantities in thought." In saying this, he was so fully satisfied that he had announced the principle of applying *every* quantity to the predicate of *every* proposition, that he made a charge of plagiarism of this principle against one who applied it after (as he supposed) seeing this announcement, and rested the proof on the (as he thought) obvious meaning of the sentence above. It is hardly requisite to say that "both have *their* quantities" is not the same as "both have *all* quantities," but generally means that one has one and another another. If any one had said that two persons "both have always their hobbies," no one would have gathered that the pair keep a pair of hobbies for their joint use. The present

To this we object: but our greater objection is to the system itself. We have not seen any defence of the following points which has a single respectable* element, except the character of its producers. The introduction 1, of a complex proposition; 2, of a proposition which is not simply contradicted by any *one* other proposition; 3, of a proposition which cannot be contradicted at all in the system; 4, of a proposition compounded of two others *already in the system*.

The notation of the system is as follows. Woodcuts† resembling — and + are used for assertion and denial; a comma signifies particular quantity; a colon signifies universal quantity. Thus *x*, + : *y* signifies "some *x* is not any *y*." And the following diagram represents the syllogism, "all *x* is all *y*, some *y* is all *z*, therefore some *x* is all *z*."

x : — : *y*, — : *z*

There is valid inference when the middle term is once at least taken universally, and one of the propositions at least is affirmative. We shall presently point out the canon of inference, when we have described a notation which we prefer. We refer the student to Sir W. Hamilton's own writings for the notation, &c. connected with his distinction of breadth and depth. We hold it quite useless to enter on the comparison of "all man is some animal," and "some animal is all man," as cases of a fundamental subdivision‡ of logic into two parts; those who can may believe that, as asserted, one of these propositions is *metaphysical* and one *logical*.

Sir W. Hamilton invited the severest criticism: he challenged it to show that his system is not more correct§ in theory than that of Aristotle, and not preferable in practice. He affirmed that his system was intended to "place the key-stone on the Aristotelic arch," and that it succeeded in so doing. We hold him to be almost a miracle of learning, and, in every sort of psychological or metaphysical notion, except only when it is mathematical, we feel him to have a true genius for conception, a mighty power of execution, and a rare talent of expression. But when quantity is in question, his power is gone. Almost in a breath he tells us, first, that his two quantities, breadth and depth, are in reality one and the same quantity; and next, that the greater the one the less is the other ('Discussions,' &c. 1st. ed., p. 644*, 2nd ed., p. 699). He confounds equation of quantity with identification of quantified matter: he asserts that a proposition is "merely" equation of quantities. He uses the phrases "equation of quantities" and "coalescence of notions" as convertible; and the prize essay of an able student, published with his sanction, announces that "predication is nothing more or less than the expression of the relation of quantity in which a notion stands to an individual, or two notions to each other."

We now proceed to state Mr. De Morgan's views, and for brevity as well as for other reasons, we shall confine ourselves to mere statement, without proof or enforcement; referring to the works previously mentioned.

The proposition in its common form is objective, or, in old phrase,

point, however, is the statement that this takes place in *common language*, and that the *ellipsis*, as he calls it, is only *frequent*, implying that the full expression is not infrequent.

* To the objection that 'All *x* is all *y*' has no single contradiction, an eminent defender replied that it *has* a contradiction; and he produced it; 'All *x* is not all *y*'; and Sir Wm. Hamilton assented: and both are right under a little admission of unusual construction. But the assailant had only objected that there was no contradiction *in the system*: and both Hamilton and his defender forgot to explain how this contradiction did not find its way *into the system*. The true explanation is that the system itself was founded, not on the laws of thought, but on an arbitrary extension of the application of language: and the end of it is that the Hamiltonian logic is *not* allowed to find language for all that is contained in thought. For both Hamilton and his defender have to go *out of the system* to find language for what must be *in thought* to those who think of the system, namely, the denial, when wanted, of the first of the propositions in the system.

† It will amuse the mathematician to see that Hamilton, to whom all mathematics was repugnant, stumbles upon + for his sign of negation, and — for his sign of affirmation.

‡ Sir W. Hamilton seems, *in logic*, to have nothing answering to the *attribute* which marks a *class*: he substitutes the concrete quality, treated as a class of individuals. He says that Leibnitz and Newton have *two* human natures, one apiece: that one attribute of Plato is 'some Athenian.' This is quite true, and the treatment of the quality, under the notion of one quality for one individual, another for another, is good in its proper and very subordinate place. But it is not connected with the great distinction of comprehension and extension, herein-before noticed.

§ His completely quantified predicate is maintained by him to be necessary to the perfect representation of common thought. A living lesson on this point was soon given. Shortly after Sir W. Hamilton's death, an ardent admirer published a manual of his system for the use of schools. But though he had seen the objection to the form 'All *x* is all *y*' having no contradiction, and Hamilton's admission and defence, he actually took 'Some *x* is not some *y*' to be the contradiction required. And when the error was pointed out in a review, he continued to maintain it, and appealed to common sense for its truth, and to Hamilton's pupils (one of whom set him right) to vouch for its correct representation of the system. The author of the manual showed no want of acuteness in other things, and his book is a valuable and well-timed proof that Hamilton's system demands more than *is* in common thought, though not more than *may be* in the thought of those who will gain it.

of first intention. It is also arithmetical in character: it either enumerates or speaks by total of enumeration, as in Every x is y , All x s are y s. It is so far not distinguishable in character from a numerically definite proposition: "Some x s are y s" and "70 x s are y s" are forms which differ only by vague and definite enumeration.

The adoption of a definite universe, as already noticed, gives precision to the privative term, not- x , the rest of the universe when x is removed. Let not- x be denoted by $\bar{x}$; not- y by $\bar{y}$, &c. And x and $\bar{x}$ are called contraries.* This introduction destroys the distinction of assertion and denial, except in a relative sense: the assertion that every x is y is the denial that any x is $\bar{y}$. Affirmation and negation must be distinguished as follows. A proposition true of x and $\bar{x}$, false of x and $\bar{x}$, is affirmative; a proposition true of x and $\bar{x}$, false of x and $\bar{x}$, is negative. Thus every thing is either x or $\bar{x}$ is negative, though assertive in this form: it is true of x and $\bar{x}$, false of x and $\bar{x}$. It is to be understood that no term used fills the universe: names which belong to the whole universe, to one part as much as to another, cannot be of any distinctive force or meaning within that universe.

Let a proposition be called universal, when the whole universe must be examined to verify it: particular, when the examination of a portion of the universe may verify it. Let a term be called total, where every instance of it must be examined before the proposition can be verified: partial, when such complete examination may not be needed.

There are two forms of predication in use: the *cumular*, as in "all x s are some y s" and some x s are not y s (are distinct from all y s); the *exemplar*, as in every (each, or any) x is some one y , and some one x (perhaps not any one) is not any one y . The cumular proposition speaks by collection; the exemplar, by selection. Grammatical correctness (representing a usual tendency of thought, though not an absolute law) allows either mode of expression in affirmatives, but demands exemplar expression in negatives; as in all x s are not any y s. The cumular and exemplar modes of expression have differences which will presently be further seen.

We first take the cumular proposition and syllogism. Let a term totally used, as x , be denoted by x or $(x$; partially, by x (or $\bar{x}$. Let affirmation be denoted by two dots, or none; negation by one dot. Let propositions be distinguished by the quantities of their terms and the *quality* (affirmative or negative): this is found to make complete distinction. Thus $(\cdot)$ means a negative proposition in which both terms are particular; and $x(\cdot)y$ is that proposition enunciated in terms of x and y . It turns out to be "Everything is either x or y ."

There are eight forms of cumular predication: four universal, with four contrary (usually called *contradictory*) particulars. These are now given, with their symbols and usual readings: and the correctness of the distribution of the words universal and particular, total and partial, may be gathered by the reader from the definitions. Each universal (U) is followed by its contrary particular (P).

- $U. x))y$. Every x is y .
- $P. x(\cdot y$. Some x s are not y s.
- $U. x)(y$. No x is y .
- $P. x))y$. Some x s are y s.
- $U. x(\cdot y$. Everything is either x or y .
- $P. x)(y$. Some things are neither x s nor y s.
- $U. x((y$. Some x s are all the y s.
- $P. x))y$. All x s are not some y s.

Contraversion—changing a name into its contrary—alters the quantity of the term, and the quality of the proposition: thus $x))y$ is $x)(\bar{y}$ and $x(\bar{y}$ and $x(\cdot y$. And a term and its contrary always enter one proposition with different quantities. *Conversion* is simply writing the propositional symbol inverted: thus $x))y$ is conversely $y((x$. We shall now use the forms $((\cdot)$ &c. to signify the propositions.

Of contraries; one must be true and one false: either $((\cdot)$ or $((\cdot)$ &c. Each universal simply contradicts one particular—the one with different quantities and quality; is inconsistent with, and therefore denies, the universals of different qualities; remains indifferent to the universal of different quantities and its contradictory; and contains the two particulars of the same quality. Thus $((\cdot)$ contradicts $((\cdot)$, that is, denies and is the only mode of denial; it denies $((\cdot)$ and $((\cdot)$ but not by simple contradiction; it co-exists with either $((\cdot)$ or $((\cdot)$; and it contains and affirms $((\cdot)$ and $((\cdot)$.

Each universal proposition has what we call *terminal ambiguity*: thus "every x is y " may coexist with either "Every y is x " or "some y s are not x s." The following is the list of propositions which, with reference to the ambiguity just noted, have what we call *terminal precision*. The symbols used to denote them are prefixed.

$x))y$, compounded of $x))y$ and $x))y$. All x s and other things besides are y s.

$x||y$, compounded of $x))y$ and $x((y$. All x s are all y s: x and y are identical terms.

$x(o)y$, compounded of $x((y$ and $x(\cdot y$. The x s contain all the y s and other things besides.

$x)o(y$, compounded of $x(\cdot y$ and $x))y$. Nothing is both x and y , and some things are neither.

* No distinction is drawn between the words *contrary* and *contradictory*, whether as to terms or propositions.

$x|\cdot y$, compounded of $x)(y$ and $x(\cdot y$. Everything either x or y and nothing both: x and y are contraries.

$x(o)y$, compounded of $x(\cdot y$ and $x))y$. Everything is either x or y , and some things are both.

Each kind of proposition is either simple or complex with respect to the other, according as we think of alternation or conjunction. Thus $((\cdot)$ is the junction of $((\cdot)$ and $((\cdot)$; but $((\cdot)$ is the alternative $((\cdot)$ or $((\cdot)$. Conversion and contraversion are under the same rules as before.

The preceding forms are completely arithmetical, and are truly particular cases of the numerical proposition, of which it will now be convenient to say something, as well as of the corresponding syllogism.

Let mxy signify that m (or more) x s are y s; then mxy signifies that m or more x s are not y s. Let u be the number of instances in the universe; let x, y, z , be the numbers of x s, y s, and z s: then $u-x, u-y, u-z$, are the numbers of $\bar{x}$ s, $\bar{y}$ s, and $\bar{z}$ s. A *spurious* proposition may exist: that is, one which by the constitution of the universe *must* be true. Thus if $x+y$ be greater than u , $(x+y-u)xy$ must be true. Every proposition has two forms: thus

$$\begin{aligned} mxy & \text{ is } (m+u-x-y)xy \\ mxy & \text{ is } (m+y-x)xy \\ mxy & \text{ is } (m+x-y)xy \\ mxy & \text{ is } (m+x+y-u)xy \end{aligned}$$

When one of the forms is spurious, the other contains a negative quantity, and is * inconceivable.

The contradiction or contrary of mxy is $(x+1-m)xy$. Hence deduce contradictions of the other forms. From mxy and nYZ we deduce $(m+n-y)xz$. That is, there is inference when the quantities of the middle term in the two premises together exceed the whole † quantity of that term. The following forms of syllogism may easily be investigated.

Premises.	Forms of conclusion.
$mXY \quad nYZ$	$(m+n-y)XZ$
$mXy \quad nYZ$	$(m+n-x)XZ$
$mXY \quad nYz$	$(m+n-z)Xz$
$mXy \quad nYz$	$(m+n+y-x-z)Xz$
	$(m+n+u-x-y-z)xz$
	$(m+n-z)Xz$
	$(m+n-x)Xz$
	$(m+n+y-u)Xz$

The proposition $x))y$ is xxY : the proposition $x(o)y$ is xxY joined with $(y-x)xy$. And so of the rest.

In the more subjective view of logic, that is, in the *mathematical* side of it, the one commonly cultivated to the exclusion of the other, the term becomes the word expressive of a *class*, and the relation of class to class is that of inclusion or exclusion, total or partial. Each term, x , divides the universe into two classes, x and $\bar{x}$. The following names may be applied to the *relations* of class:—

- $x))y$ x is a *species* ‡ of y ; y is a *genus* of x
- $x(\cdot y$ x is an *exient* of y ; y is a *deficient* of x
- $x)(y$ x and y are *externals* of each other, or *co-externals*
- $x(\cdot y$ x and y are *partients* of each other, or *co-partients*
- $x(\cdot y$ x and y are *complements* of each other
- $x))y$ x and y are *co-inadequates* of each other
- $x((y$ x is a *genus* of y ; y is a *species* of x
- $x(\cdot y$ x is a *deficient* of y ; y is an *exient* of x .

The propositions of terminal precision may now be stated under the following nomenclature:—

- $x(o)y$ x a *subidentical* of y
- $x||y$ x an *identical* of y
- $x(o)y$ x a *superidentical* of y
- $x(o)y$ x a *subcontrary* of y
- $x|\cdot y$ x a *contrary* of y
- $x(o)y$ x a *supercontrary* of y

We now return to propositions of terminal ambiguity. When two propositions are joined together, between x and y , and y and z , there is a valid syllogism, that is, one which yields a necessary conclusion, 1, when both premises are universal; 2, when, one premise only being universal, the middle term has *different* quantities in the two; or when the *spiculae* turn the same way. And the conclusion is found by erasing the symbols of the middle term. Thus $((\cdot)$ gives a valid syllogism: for though $((\cdot)$ is particular, there is a universal and a particular quantity in the middle term. The conclusion is $((\cdot)$ or $((\cdot)$. By this we mean

* Not strictly inconceivable, to those who remember the full signification of the negative quantity as here defined. Thus $(-7)xy$ means that -7 or more x s are y s: begin at the point of *more* at which logical predication begins to be conceivable, and we have '0 or more x s are y s,' a proposition which is simply spurious.

† This is what Hamilton calls the *ultra-total* quantification of the middle term. Lambert first thought of this principle: Mr. De Morgan, without any knowledge of Lambert, reconceived it and extended its use. Sir W. Hamilton, who did not know of Lambert till after this, states first, that he had himself thought of the principle and thrown it away; secondly, that Mr. De Morgan took it from Lambert: and this though Mr. De Morgan had explicitly stated that he never knew of Lambert's work till after his own paper on the subject had been published.

‡ Here is a departure from the common language. Usually $x(o)y$ is signified when we say that x is a species of y , and y a genus of x . We take the species as being, possibly, the whole genus: just as *some* is possibly *all*.

that $x(\cdot)y(\cdot)z$ gives $x(\cdot)z$, or that $x(\cdot)y$ and $y(\cdot)z$ give $x(\cdot)z$. That is, if "Every thing is either x or y ," and "Some z s are not y s," it follows that "Some x s are z s."

There are 32 valid forms. 1. Eight are *universal*, with universal premises and conclusion; being all which have differently quantified middle terms. They are as in $((\cdot), (\cdot))$, $((\cdot), (\cdot))$, &c. 2. Eight are *minor particulars*, with the *minor* (or first) premise particular, and a particular conclusion; as $((\cdot), (\cdot))$, $((\cdot), (\cdot))$, &c. 3. Eight are *major particulars*, with the *major* (or second) premise particular, and a particular conclusion; as $((\cdot), (\cdot))$, $((\cdot), (\cdot))$, &c. 4. Eight are *strengthened particulars*, universal premises with the middle term similarly quantified in the two, and a particular conclusion; as in $((\cdot), (\cdot))$, $((\cdot), (\cdot))$, &c.

In every syllogism, the terms being notions of class, there is a combination of premising relations in the concluding relation. Thus in "No x is y , some y s are z s, therefore some z s are not x s," or in " $x(\cdot)y(\cdot)z$ gives $x(\cdot)z$," we read that x is an external of y , and y a partient of z , whence x is a deficient of z . And we see that an external of a partient is a deficient. Apply this to all the cases. Thus in $((\cdot), (\cdot))$, giving $((\cdot), (\cdot))$, we read that a complement of an external is a genus.

The propositions of terminal precision give syllogisms having conclusions also of terminal precision by joining two in which the middle term has different quantities; as in $x(\cdot)y(\cdot)z$, giving $x(\cdot)z$. This means that if everything be x or y , and some things both, and if nothing be both y and z , and some things neither, it follows that the x s contain all the z s, and more. The combination of relations here seen is as follows: a supercontrary of a subcontrary is a superidentical.

When the notion of figure is taken into account [SYLLOGISM; RELATION], its force and meaning is best seen by stating the combination of relation in the different figures. Thus when we say a species of a species is a species, we speak in the first figure, and compare the minor with the major by the relation which the minor stands in to the middle and the middle to the major. When we read it thus—species and genus of the same are species and genus of one another,—we use the second figure, and compare both major and minor with the middle. When we say that those to which the same is genus and species are species and genus of one another, we use the third figure, and compare the middle term with both major and minor. And when we speak thus,—that to which another is species of species is a genus of that other,—we use the fourth figure, that is, the first figure with the concluding relation inverted.

We now come to the *exemplar* form, already spoken of. Let $x(\cdot)$ and (x) signify *any one* x : let (x) and $x(\cdot)$ signify *some one* x , it not being known, even if true, that we may say *any one*.

The list of propositions is as follows. Each universal is followed by its contradicting particular:—

- U. $x(\cdot)y$ Any one x is any one y . This means that there is but one x and one y , and the x is the y .
- P. $x(\cdot)y$ Some one x is not some one y . Either x and y are not both singular: or if both singular, not identical.
- U. $x((\cdot)y$ Any one x is some one y ; or every x is y .
- P. $x((\cdot)y$ Some one x is not any one y ; or some x s are not y s.
- U. $x((\cdot)y$ Some one x is any one y ; or every y is x .
- P. $x((\cdot)y$ Any one x is not some one y ; or some y s are not x s.
- U. $x(\cdot)y$ Any one x is not any one y ; or no x is y .
- P. $x(\cdot)y$ Some one x is some one y ; or some x s are y s.

Omit the word *one* throughout, for *any* read *all* when the word is in italics, and we have Hamilton's* system, provided the first pair be not read as contradictions.

There are 36 valid forms of syllogism, both in the *exemplar* reading and in Hamilton's reading. All that is required is one affirmative premise, and one total occurrence of the middle term. In the *exemplar* system, the rule of inference is as above described for the *cumular* system. In Hamilton's system there is this modification: when the middle terms are of different quantities, a concluding term which is total, with a spicula turning a different way from those of the middle term, must be altered from total to partial, if its proposition be affirmative. Thus, $((\cdot), (\cdot))$ in the *exemplar* system gives $((\cdot), (\cdot))$, but in Hamilton's system it gives $((\cdot), (\cdot))$. Or, "Any one x is any one y , and some one y is some one z ," gives "Any one x is some one z ," but "All x is all y , and some y is some z ," gives "Some x is some z ." Again, $((\cdot), (\cdot))$ in Hamilton's system, gives $((\cdot), (\cdot))$, not $((\cdot), (\cdot))$, as in the *exemplar* system. The reason of this difference will easily appear, on consideration.

The *exemplar* proposition is often used, as distinguished from the *cumular*. It is, for example, the proposition of geometry. When Euclid proves that *all* isosceles triangles are of equal angles at the bases, he shows that *any* isosceles triangle is so, and he demonstrates only to those who can see that nothing is assumed in his demonstration which limits the selection.

The numerical syllogism leads to a species of syllogism which is

* Sir W. Hamilton mixed the *exemplar* and *cumular* forms in obedience to grammar. His system suggested the one before us, which its proposer holds to be a correction. Hamilton himself rejected the correction with his usual piquant scorn, declaring that it stands alone—in badness, that is—in the whole history of science. Those, therefore, who comply with his wish, will hand it over entire to Mr. De Morgan, who will accept it all, if given, but cannot claim it all.

occasionally used, but cannot be reduced to a common syllogism. It is the syllogism of *transposed quantity*, in which one of the concluding terms enters with the whole quantity of the other, or of its contrary. For instance, "For every man in the house there is a person who is aged; some of the men are not aged; therefore some of the persons in the house are not men." Nothing has yet been printed on the laws of this syllogism of transposed quantity: the following brief rules will enable the reader to detect the cases, which are sixty-four in number.

Let a *particular* proposition which has a term of the whole quantity of an *external* term—that is, in another proposition—be called an *external universal*, the ordinary universal being called *internal*. The proposition has a *receiving* term; the other proposition has an *imparting* term. Let the receiving term be distinguished by a hyphen below its spicula; the imparting term by a hyphen above. Thus $x((\cdot)y(\cdot)z$ means as follows:—Every x is y ; for every x there is a z which is not y . But there is no valid syllogism when a term taken totally imparts its quantity: in the case before us the only chance of a valid inference arises from allowing x , which enters partially, to impart its quantity; as in "Every x is y ; for every x there is a z which is not y ." This being understood, and also that in forming the conclusion every imparting term must change its quantity, the rules for detecting valid syllogism are precisely those of the *cumular* syllogism already described. That is, any two universals, each of either kind, give a conclusion; and one universal of either kind and one particular, if the middle terms have different quantities in the two.

Then $((\cdot), (\cdot))$, having two external universals, is valid, and gives $((\cdot), (\cdot))$. That is, from "For every z there is an x which is y , and for every x there is a y which is not z ," we deduce "Some z s are not y s."

Again, $((\cdot), (\cdot))$ has an external and an internal universal, and gives $((\cdot), (\cdot))$. "For every z there is an x which is y , and every y is z " gives Every z is x . And $((\cdot), (\cdot))$, having an external universal and a particular, with middle term of different quantities in the two, is valid, and gives $((\cdot), (\cdot))$. That is, from "For every z there is something neither x nor y ; some y s are not z s," we deduce "Some z s are not x s."

Few propositions that ever come before the human mind require closer attention than these transposed syllogisms. They are easily demonstrated from the general forms of numerical syllogism; not so easily by independent thought.

We shall now proceed to compare the mathematical and metaphysical sides of logic. A term may be formed by junction of terms in two ways. 1. By *aggregation*, as in what we represent by (A, B, C) , which stands for all that is in A , in B , in C , or in two or more. 2. By *composition*, as in what we represent by $(A-B-C)$, or $(A B C)$, meaning all that is common to all the three terms A, B, C . The contrary of an aggregate is the compound of the contraries of the aggregants: either (A, B) or (a, b) . The contrary of a compound is the aggregate of the contraries of the components: either $(A B)$ or (a, b) .

The term, considered as aggregated of aggregants, is viewed in *extent*; as a compound of components, in *intent*. For *total* and *partial* we now substitute the words *full* and *vague*, to get rid of the wrong opposition which *total* and *partial* suggest; for the term called *partial* is not necessarily partial at all, it is only not known to be total. And this ambiguity has led acute* logical writers into absolute mistake. In this matter we follow Hamilton, who justly and acutely remarked that "It is only as indefinite that particular, it is only as definite that individual and general, quantities have any (and the same) logical avail." The word *indefinite* completely describes the word *particular*, or *partial*, as commonly used: we only use *vague* as a shorter word. But the *universal* or *total* of logicians is more than *definite*: it is the maximum of definiteness, and we use *full* as more correctly descriptive. *Two-sevenths* is as *definite* as *all*.

Extent and intent are the two logical *tensions*. The elements of extent are aggregants; the elements of intent are components. When one tension is full, the other is vague; when one tension is vague, the other is full. Thus $x(\cdot)$ signifies that x is taken fully in extent, vaguely in intent; and (x) signifies that x is taken vaguely in extent, and fully in intent. When a tension is full, an existing element may be dismissed, but a new one cannot be admitted; when a tension is vague,

* In Hamilton's system, "Every x is y " is read "All x is some y ," and "Every y is x " is read "All y is some x ." But ("Discussions," &c., 2nd ed. p. 688,) he says that "All x is some y ," and "Some x is all y ," are impossible, that is, cannot be true together, "unless some be identified with all." This supposition he treats as an absurdity: hard pushed in controversy, he was misled by the ambiguity on which this note is written. The *some*, even of his own system, is a *possibly-all*: how otherwise can he dare to render "Every x is y " by "All x is some y ?" The junction of the two propositions determines the *universality* of the so-called *particular*. This looks very like nonsense; but the fault is in the language of the logicians. Substitute *full* and *vague*: the word *some* is *vague* in either proposition taken apart: but the junction restrains the *vagueness*, and turns the indefinite into a definite, *vague* into *full*. Just as in algebra one relation between two unknown quantities may leave a vagueness which a second relation turns into comparative definiteness. Our two propositions are xy and yx . The first gives $x =$ or $< y$; the second gives $y =$ or $< x$, that is, $x - y$ and $y - x$ are neither of them negative; whence $x = y$, so that x is full in the first proposition, and x in the second.

The word *impossible*, which Mr. De Morgan attributes to Sir W. Hamilton, is in truth only revived by him. It is a very useful word.

Most Unitarian divines consider it to be used either for God himself, or as an abstract term for the wisdom and intelligence of God which was fully imparted to Christ to fit him for his mission.

Those who attribute to the Logos a personal existence give different reasons for the origin of the name. Some explain it to mean the *speaker* or *teacher*, by metonymy, as Christ is called by John the Light, the Way, the Truth, the Life; others interpret it *the promised one*; and others consider that as speech (*λόγος*) is a *medium* of rational communication, so the name Logos is given to the *Mediator* between God and man, one who speaks to man in the name of God.

LOGWOOD. [HÆMATOXYLON.]

LOLLARDS, a religious sect which arose in Germany at the beginning of the 14th century, and differed in many points of doctrine from the church of Rome, more especially as regarded the mass, extreme unction, and atonement for sin. It took its name, according to some writers, from Walter Lollard, or Lolhard, who was burnt alive for these doctrines at Cologne in 1322; but it would seem that Walter rather received his name from the sect, than gave a name to it. The real origin of the term appears to be the German *lullen*, *lollen*, or *lallen*, to sing, with the well-known termination of *hard*, which is subjoined to so many German words; and it implied a person who was continually praising God in sacred songs. Lollard subsequently became a term of reproach for all heretics, who were supposed to conceal erroneous doctrines under the appearance of piety. In England, at the close of the 14th century, the earliest source was the invectives against the clergy in the poem by Langland of 'The Vision of Piers Ploughman,' and the name was afterwards bestowed on the followers of Wycliffe. Knighton, noticing the success of that reformer's doctrines (Twysd. 'Script.' x. col. 2664), says, "more than half of the people of England in a few years became Lollards."

LOMBARD, an ancient name in England for a banker. It was derived from the Langobardi, or Lombards, a company of Italian merchants, the great money-changers and usurers of the 13th century, who settled in England before the year 1274, and took up their first residence in a street of the city, still called, from them, Lombard Street. They appear to have been first employed in England as bankers or money agents for the popes, and in the reign of Edward I. there were four companies of Sieneese merchants settled in London, under the title of Campsores Papæ.

Stowe, in his 'Survey of London,' says, "Then have ye Lombard Street, so called of the Longobards and other merchants, strangers of diverse nations, assembling there twice every day," which had that name certainly before the time of Edward II. The meeting of which merchants and others there continued until the 22nd of December in the year 1568, "on the which day the said merchants began to make their meetings at the Bourse, a place then new builded for that purpose in the ward of Cornhill, and was since by her majesty, Queen Elizabeth, named the Royal Exchange."

The Italians were not only bankers and money-lenders, but wealthy merchants; and afforded the assistance of their capital by advances for wool and other productions of the country, on terms which often occasioned complaints of usury against them. Under the protection of the pope they prospered for a considerable time; but the loans advanced by them to Edward III. (who had made the Bardi and Peruzzi, merchants of Florence, his agents, his revenues and wools going through their hands, while they furnished his expenses during the war with France) so far exceeded the receipts, that he owed to one firm 180,000 and to the other 135,000 marks. These sums they lost; and the occurrence greatly shook the confidence of the Lombard bankers. They continued, however, to follow their trade, and when Henry VI. borrowed money of them, they had the customs mortgaged to them for security.

(E. A. Bond, in *Archæologia*, vol. xxviii. 1839.)

LOMBARDIC ARCHITECTURE. [ROMANESQUE.]

LONG, a character used in old music, formed of a breve with a stem added, thus—

and equal in time, or duration, to two breves, or four semi-breves, &c. It is rarely met with in compositions of later date than the middle of the 17th century, and is now hardly known, except to the musical antiquary.

Still more obsolete is the LARGE, a character nearly in the above form, but the head is much more extended. *Ex.*:

This is the longest note ever used in musical notation, and equal to two longs, four breves, &c.

LONGITUDE and LATITUDE. These terms mean different things as applied to a point of the earth or a star in the heavens; and

we must accordingly distinguish between *geographical* latitude and longitude and *celestial* latitude and longitude.

The latitude of a star in the heavens is its angular distance from the ecliptic, measured on a great circle drawn through the star and pole of the ecliptic. It differs from the DECLINATION only in this, that the ecliptic is used instead of the equator. The longitude of a star is the angle made by the circle on which latitude is measured with the circle which passes through the pole of the ecliptic and the vernal intersection of the equator and ecliptic. Thus a star on the ecliptic has no latitude, and one which lies directly between a pole of the ecliptic and the vernal equinox has no longitude. The use of celestial longitudes and latitudes has in great measure been superseded by those of right ascensions and declinations.

The meaning of the term geographical longitude is the same whether we consider the earth as a sphere or a spheroid. It is the angle contained between the plane of the meridian of the place, and that of some one meridian which is fixed on as the starting-place. Thus we choose the observatory of Greenwich, and the French that of Paris, as being in the first meridian; and while we express the relative position of the two observatories (in longitude) by saying that Paris is 2° 20' 24" east of Greenwich, the French describe Greenwich as 2° 20' 24" west of Paris.

It is usual to measure terrestrial longitudes in time [ANGLE; TIME], the whole circuit of the globe being supposed described (as in the diurnal motion) in 24 hours. It is also usual to reckon longitudes to 180° east or west, without proceeding farther. Thus a motion in longitude of 185° east will bring the traveller into 175° of west longitude. In astronomical writings, however, longitudes (both geographical and celestial) are measured all round the globe.

Supposing the earth to be a sphere, the latitude of a place is the angle subtended at the centre by the arc of the MERIDIAN intercepted between the place and the equator. This angle is equal to the altitude of the pole of the heavens at the place; and the determination of the altitude of the pole is the method usually resorted to for determining the latitude. But the earth not being precisely a sphere, but a spheroid [GEODESY], the zenith line (which is a perpendicular to the tangent plane) does not pass exactly through the centre, and the altitude of the pole is not precisely the angle subtended at the centre by the arc of the meridian. Still, however, the altitude of the pole is called the latitude of the place; and it must be distinctly understood that a latitude, astronomically determined, is the angle made by a line which is vertical at the place with its projection on the equator. The angle subtended at the centre of the earth by the arc of the meridian is less than the altitude of the pole by a number of seconds, equal to

$$\frac{\epsilon}{\sin 1''} \times \sin \text{twice the latitude,}$$

where ϵ is the ELLIPTICITY. Assuming this at $\frac{1}{305}$, the above is such a proportion of $11\frac{1}{2}'$ as the sine of twice the latitude is of unity.

The reason why the preceding is not of more importance in the construction of maps lies in this, that when a large portion of the earth is mapped, the scale is necessarily too small to make such an error of any consequence; and when a small portion of the earth is taken, the error is nearly the same in every part of the map, and relative positions are not sensibly affected.

The method of finding longitudes and latitudes is given in the next article. The history of this problem, or rather of that of finding the longitude in particular, divides itself into two portions: the first, or the account of the real progress of the problem, is so mixed up with the history of astronomy and horology, that it would be useless to attempt it within any limits which we could afford; the second is that of the speculators who have misunderstood the problem, and is not worth the recital. Since, however, there are still persons who imagine that some mysterious *method* is yet attainable, by which the longitude is to be found, and since the conductors of the newspaper press are not all sufficiently aware of the state of the problem to prevent the insertion from time to time of paragraphs which create a most erroneous impression, we shall briefly point out the source of the fallacy which has misled so many persons.

The determination of the longitude requires simply accurate instruments for the measurement of the positions of the heavenly bodies, and one or other of the two following—either perfectly correct watches, or perfectly accurate tables of the lunar motions. The legislature of Queen Anne, which passed an Act offering a reward for the discovery of the longitude, the problem being then very inaccurately solved, for want of one or the other, good watches or lunar tables, never contemplated the invention of a *method*, but only the means of making existing methods sufficiently accurate. And the legislature of George III., which repealed the former Act and substituted another, specifically limited the reward to those who should either proceed by improvement of chronometers or of lunar table. The rewards which were given were to Harrison for the former, and to Mayer's executors for the latter. The latter Act is now repealed, and there does not exist any parliamentary offer of a sum of money for further improvements.

Many persons, imagining that, as in the case of the quadrature of the circle, &c., a theoretical difficulty existed, have employed themselves in endeavouring to invent a method, imagining that they should obtain

the prize held out by the legislature. Some persons still occupy themselves in this manner; and it is impossible to persuade them either of the repeal of the Acts of Parliament, or of their having mistaken the nature of the difficulty, which is now, for all practical purposes, entirely conquered. It is impossible to find the latitude of a place without knowing the position of the equator in the heavens, or the longitude without knowing the meridian of Greenwich. The equator has a real existence in the heavens, since its pole is the immovable point of the heavens, which can be detected (though it is not absolutely occupied by a star) from observation of the motion of the stars, which always preserve their distance from the pole. But the meridian of Greenwich, a purely arbitrary circle of the earth, determined merely by the will of Charles II., that an observatory should be built on a certain hill near London, has no representative in the heavens. The only method, then, of finding longitude of the heavenly bodies is by finding the hour of the day which it is at Greenwich, at a particular hour on the spot whose longitude is required. It is then known how much of 360 degrees is revolved through by the earth in the period which brings a star from the meridian of the place upon the meridian of Greenwich, or *vice versa*; and this angle is the longitude. A watch which goes correctly and is set at Greenwich will carry the time at that place all over the world; or a celestial phenomenon, of which the Greenwich time may be predicted, will, if the moment of its happening be observed at any other place, give the difference of times at the moment of observation. Any proposal for finding the longitude *astronomically*, which does not depend on one or the other of these principles, is useless, unless it be that of actually measuring the distance between the given place and Greenwich, the latitudes of both being known. Whether it be possible to use any other than astronomical means for the purpose, it would be presumptuous to decide; but there certainly is no other method which offers the most distant prospect of success.

LONGITUDE AND LATITUDE, METHODS OF FINDING. We shall classify the various modes of determining geographical latitude and longitude, partly by the instrumental means of the observer and partly by the nature of the phenomena. The problems are of course the same whatever instrument is employed, for the latitude of a place is the altitude of the pole of the heavens at that place, and the longitude is the difference between the time on the first meridian (we shall always suppose Greenwich to be the first meridian) and the time at the place, at the same physical instant.

Determination of the Latitude at Fixed Observatories and Independently.—1. In determining the latitude at fixed observatories which are furnished with accurate circles, mural, transit, or altitude and azimuth circles [CIRCLE], the altitudes or zenith distances of circumpolar stars are observed above and below the pole. When these are properly reduced, the place of the pole (which lies between the places of upper and lower culmination of each star) is known, and hence the latitude is found. The first object of all astronomers is to fix the latitude of their place of observation, and the details of this operation will be found in the beginning of most of the published series of observations. The account of the latitude of Greenwich in the Greenwich Observations for 1836, p. lviii., of Cambridge in the Observations of 1833-4-5, and of Edinburgh, 1834-5, may be consulted by those who wish to know what the process is, with the most perfect means which we at present possess.

2. Again, if the altitudes or zenith distances of the sun be observed several days before and after the summer and winter solstices, the altitude or zenith distance of the middle point, that is, of the equator, may be deduced. Since the tables of refraction have been perfected by Bessel, these observations give a satisfactory latitude. Both methods may be considered to be independent, as they do not draw their data from other observatories, and no great accuracy is required in the solar tables to reduce the observations of the sun to the solstice. (Pond's 'Lat., Greenwich Observations,' part v.)

In the observatories of Europe, and generally where the visible pole of the heavens is tolerably high, the latitude is best determined by circumpolar stars; near the equator an independent latitude must be deduced from circumsolstitial observations.

3. Before the introduction of circles, the latitude in fixed observatories was derived from combining two instruments, the mural QUADRANT and the ZENITH SECTOR. The zenith distances of stars near the zenith, and to the north or south of it, were observed by the zenith sector, and also the distances of the same stars from the pole or the equator by the quadrants; hence the arc between the pole and zenith (the co-latitude), or between the zenith and equator (the latitude), was deduced. The place of the pole was found on the north quadrant from circumpolar stars, and the place of the equator on the south quadrant, from observations of the sun near the solstices, as we have described above. When the present zenith tube was erected at Greenwich, one of its intended uses was to perform the same office for the mural circle as the original zenith sector did for the quadrants.

Determination of the Latitude Differentially.—1. The ZENITH SECTOR, when of the proper size and construction, is perhaps the most accurate instrument for determining latitudes *differentially*, that is, assuming data which are either known or can be obtained from fixed observatories. With this instrument, the meridian zenith distances of several stars which pass near the zenith may be observed with great certainty;

and as the polar distances of those stars are or may be determined at first-rate observatories, the polar distance of the zenith, or the co-latitude, is known. The latitudes for the trigonometrical survey of Great Britain are thus deduced by comparison with Greenwich, the instrument employed being a very fine 8-foot zenith sector by Ramsden. With a better knowledge of the proper motion of the stars, the sector might be used at two places, and the arc between those places obtained from observations of the same stars at two epochs, without reference to any other observations; but at present it is safer, when practicable, to refer directly to corresponding observations made at a fixed observatory.

2. Another differential method has lately been much used (at least by continental astronomers), in which the transit instrument alone is

employed. [TRANSIT.] The axis of the instrument is placed north and south, and carefully levelled, in which case its line of sight will describe the prime vertical. In the figure, let P be the place of the pole, Z the zenith, EZW the prime vertical, which is also the line described by the middle wire of the telescope when it revolves. Let a star, of which the polar distance is well known, be observed at S and S', and the times noted. Then PS, the polar distance of the star, is known, and the angle SPS' is equal to the time between the observations, and consequently $\frac{1}{2} SPS'$, or SPZ, is known; hence we have SP and SPZ in the right-angled spherical triangle SPZ, and $\tan PZ = \tan PS \times \cos \angle SPS'$, from which PZ, or the co-latitude, is obtained. This is perhaps the most accurate mode of determining the latitude with moderate instrumental means. The transit should be reversed on alternate nights, so as to get rid of the effect of imperfect collimation or unequal pivots, and the level applied repeatedly before and after the observations. The method depends mainly upon the delicacy of the level and the perfect truth of form in the pivots, and when all precautions are taken the results are surprisingly good. The supports of the instrument must also be perfectly steady during the levelling and the observation. Differences of latitude may be determined by the transit instrument independently, by observing the same stars at the two stations. In this case any error in the assumed polar distance of the stars will not affect the accuracy of the result.

3. If an observer can carry with him a circle, either an altitude and azimuth, or a repeating circle, he may determine the latitude by circumpolar stars independently: but it is better to observe the zenith distances of well known stars several minutes before and after they pass the meridian.* [CIRCLE; REPEATING CIRCLE.] The reduction to the meridian is easily computed [REPEATING CIRCLE], and the places of the stars inserted in the 'Nautical Almanac' are sufficiently accurate. It is advisable to observe stars at different zenith distances from 70° on each side, to near the zenith, because if there be any fault in the instrument which depends on the zenith distance, the stars will be affected similarly on both sides of the zenith, that is, the zenith distances to the north and south will both be too large or too small. Now as the co-latitude is equal to the zenith distance $\pm$ the polar distance when the star is north of the zenith (+ when observed above the pole and - when observed below) and is equal to the polar distance - zenith distance when the star is south of the zenith, it is clear that an error in the zenith distance will have precisely opposite effects on the co-latitude deduced from a north and from a south star. Besides, the coincidence or discrepancy of the observations will afford a tolerable notion of the instrument and the observer, and of the value of the final result. The repeating circle was at one time over estimated, and perhaps at present is not quite rated at its true worth. A careful and intelligent observer will come very near the truth with it, or with the altitude and azimuth circle. Both are rather troublesome to use, and both require either a very solid support, or a second observer to read the level while the first observer bisects the star and notes the time. Neither can they be considered as portable in ordinary circumstances, when large enough for convenient use. The altitude circle should scarcely be less than 12 inches in diameter in either construction. On the whole we are inclined to prefer the repeating circle as a travelling instrument, and the altitude and azimuth for a permanent situation;

* The number of minutes which it will be prudent to observe depends on several circumstances. If the time is known to one second, which it ought to be, the observations may be commenced when an error of 1" in the time will affect the latitude 1". In ordinary cases, and for observers who do not understand the reason of the thing, 10" on each side of the meridian is a sufficient direction.

but it must be confessed that few observers have the patience or skill to get the greatest possible accuracy out of either. The observations should be confined to stars, as neither of these instruments will keep its adjustments well under the sun.

The repeating circle was used by the French astronomers to determine the latitudes in their great survey. Since that time the instrument has been much better made, and the catalogues of stars which have issued from Königsberg, Greenwich, and Cambridge, have supplied more accurate and convenient means of using it. If the levels are very good and sensible, we think that the observations of one fine night, everything being favourable, should bring out the latitude within 2" or 3".

4. The last class of instruments to be noticed is that of reflecting instruments, including the reflecting circle of Troughton, the repeating reflecting circle of Borda, and the sextant of Hadley. These will be described under the article *SEXTANT*, as the title best suited to their essential quality of reflection. At present we must suppose a general knowledge of their nature. And first we will suppose the observer to have a stand and a mercurial or other horizon. In this case, standard stars should be observed several minutes before and after the meridian passage to the north and south, between the altitudes of 15° and 60°, and as much as possible in pairs, that is, for each star to the north, a star to the south should be observed about the same altitude, or two, one higher and the other lower, so that the mean altitude should nearly correspond. Whatever errors may exist in the division, glasses, &c., will be the same in each star of the pair, and as the error will affect the latitude differently, the mean latitude will be free from the error very nearly. In this way several pairs may be observed, taking the stars of the 'Nautical Almanac,' and the mean of the whole will come out very near the truth. With a good sextant or circle, and a mercurial horizon, we believe that a careful observer would get the latitude within 5", in one fine night. It is, however, supposed that everything is favourable, and especially that the instrument is supported on a stand. This is absolutely necessary for the accurate observation of stars, which dance very perplexingly when the instrument is held in the hand, and a high power applied. If a stand cannot be afforded, the sun is far the best object to observe with a reflecting instrument. It is always supposed that the observations are made for several minutes before and after the meridian passage, and the time noted for computing the reduction to the meridian. The meridian altitude of the sun, such as it would be if observed on the meridian and freed from instrumental and other errors, is then computed, and as the longitude of the place is known, at least approximately, the declination of the sun at its passage over that meridian may be computed from the 'Nautical Almanac.' The meridian altitude + the south declination of the sun, or — the north declination, is, in the northern hemisphere, the co-latitude of the place. With Troughton's circle, the limbs are alternately observed, to get rid of the sun's diameter, and the number of observations, forwards and backwards, should be equal, so as to get rid of the index error. With the repeating reflecting circle, the observations should also be of the upper and lower limbs alternately, and should be carried quite round the circle, so as to get rid of excentricity. In the sextant the index error should be carefully determined before and after each day's observations, and the alternate limbs observed exactly as with the circles. There is, however, no way of getting rid of excentricity in the sextant by observing one object, and any fault in determining the index error will vitiate the latitude to half its amount. While the circles will probably give a latitude to nearly 5", with a very careful series of observations of the sun, the sextant used with equal care might be out 10" or 15". It is evident therefore, that where accuracy is an object, the observer ought, if possible, either to use a circle or to mount the sextant upon a stand, and observe stars as we have above described. It is an additional reason to carry a stand, when practicable, that in low latitudes the sun cannot be observed at all for the latitude, nor any object which is elevated 65° or 70°. In this case stars must be used; and without a stand, the observation, using high magnifying powers, is difficult and unsatisfactory. In speaking of the horizon we always mean a mercurial horizon, except another is specified. The glasses of the roof should be truly plane and parallel, but by reversing the horizon for half the observations any error of this kind is destroyed. The mercurial horizon is unfortunately heavy and inconvenient, and troublesome from its tremors wherever there is any motion. Several substitutes have been used. Oil or treacle has been adopted with good success where the shaking from carriages, &c., has prevented the use of mercury. Sometimes a piece of glass is set horizontal by a level applied to its surface, or by a fluid below it, so as to get a reflecting surface, but these generally absorb too much light to be used conveniently for stars, and are not very trustworthy. The best substitute seems to be a piece of speculum metal, ground plane, and laid horizontal by a level. It is certainly the brightest, and therefore the best for stars, but it must be remembered that horizons which are not self-regulated, by being fluid, are scarcely to be trusted under a hot sun. Troughton's reflecting circle is rather heavy, and reading three verniers for every observation is troublesome, especially at night, but it is very accurate, and fewer observations are required. Borda's reflecting circle may be made much smaller and lighter, but demands the most exquisite workmanship, a greater number of observations, and more reduction. The simple sextant is

more manageable, but requires greater precautions and checks in its use. But with any of these a skilful observer will get the latitude very nearly. Sextants are made of all sizes from 10 inches radius (which is probably not so good as 8 inches) down to the snuff-box sextant of 1½ inches radius. For travellers who cannot afford to carry much weight, the 3-inch sextant is very convenient. In a communication to the Royal Astronomical Society, Mr. Lassell states, that with a 3-inch sextant made by Dollond, which packs up, stand, horizon, and all, in a box 4.3 inches square and 2.7 deep, he found that he could get the latitude within 10", and the time to 1.0 by observations of stars. The horizon was of speculum metal, ground by himself, and set true by a level. The observations sent with the account completely justify Mr. Lassell's opinion, but one observer differs more from another in sextant observations than in any other class of astronomical instruments; with the snuff-box sextant, altitudes may be got within 1'. The state of the barometer and thermometer must be noted at the time of all observations for the latitude, in order to compute the true refraction. At the same time we may remark, that if the observations be *balanced*, that is, if the altitudes to the north have nearly corresponding altitudes to the south, the refraction will affect the observations like an instrumental error, and the variations depending on the barometer and thermometer will be quite insensible.

5. Observations of Polaris may be taken at any time for the latitude, and there are tables for *approximate* reduction given in the 'Nautical Almanac' for each year.

6. At sea the sextant is the only instrument which can be used, and the latitude is generally got by observing the altitude of the sun's lower limb when on the meridian, above the sea horizon. This is rather a rude process, but the resulting latitudes are generally true to 1', or at worst to 2'. The moon, since 1834, the date of the improved and extended 'Nautical Almanac,' may be very conveniently used for finding the latitude at sea, and the brighter planets and stars are often observable on the meridian. The latitude may also be deduced from two altitudes of the sun, and the time elapsed between the observations, or indeed from any two altitudes of two known celestial bodies, one of which is near the meridian, and the other distant from it, as persons not acquainted with spherical trigonometry may satisfy themselves on the celestial globe. There is a considerable difficulty in seeing the sea horizon by night, which is somewhat reduced by getting as near the level of it as you can.

Determination of the Longitude.—The determination of the longitude of any place on the earth's surface, astronomically considered, resolves itself into two parts, the finding the time at the place of observation, and finding the time, at the same moment, on the first meridian (we shall always speak of Greenwich), or at any place the longitude of which from Greenwich is well known. It will be more convenient to classify the methods of finding the longitude by the phenomena than by the instruments.

Determination of Time at the Place.—1. This is best and most easily done by a transit instrument, and the time, when found, is kept by a clock or chronometer. [TRANSIT.] The transit however is neither a very portable instrument, nor is a proper situation for it, we mean one sufficiently steady, readily found.

2. The time can also be found from the altitude of the sun, planets,

or stars out of the meridian. Thus let P be the pole, Z the zenith, and Z S the zenith distance, or S H the altitude of any heavenly body, the right ascension and declination of which are well known, and consequently the polar distance P S. From these data and P Z the co-latitude of the place, the angle Z P S can be computed, called the hour angle, and this, if the body be the sun, and to the west of the meridian, is the *apparent* time after noon; or if the sun be to the east, the hour angle is the *apparent* time before noon. This apparent time is easily reduced to *mean* time with the data of the 'Nautical Almanac.' When the object observed is a planet or star, the hour angle being added to the right ascension when the body is to the west, or subtracted from the right ascension when the body is east, will give the sidereal time, which can be reduced to mean solar time with only an approximate knowledge of the longitude. The problem therefore of finding the time consists generally in observing the altitude or zenith distance of any known object, and determining the hour angle from it. The repeating or altitude and azimuth circles are very fit for this purpose, but the most usual and portable instrument is a reflecting circle or sextant with its horizon and a chronometer. The observations of altitude should be made as much as possible on the prime vertical, that is, when the object is east or west. Again, to get rid of instrumental error, and also to save computation, the sun should be observed, when

convenient and possible, at the same altitude morning and evening. We should also recommend when the sun is observed that both limbs should be observed without moving the index. For instance, if in the morning the sun were about 14° high, set the instrument to 30° , note the instant when the upper limb by reflection touches the upper limb seen in the horizon, read off the angle very carefully, wait till the lower limbs form their contact, and note the time. Then set to $31^\circ 30'$ or 32° and proceed as before, and repeat the operation, having again set forward $1^\circ 30'$ or 2° . The observer has then several checks without trouble, for the time in which the sun rises through a diameter will be sensibly equal or vary uniformly; and in like manner the times of rising through $1^\circ 30'$ or 2° will point out if any of the usual errors have been committed. In the afternoon the same process should be repeated in an inverse order, and the time of apparent noon deduced from each pair.* It is to be understood as a universal rule, that the index error is to be carefully determined, and the barometer and thermometer noted whenever observations of altitude for time or latitude are made.

3. The same mode of observing equal altitudes might be applied to stars, but the observations would be extended to very inconvenient hours, and it is nearly as accurate to observe two bright stars, one to the east and the other to the west, and if possible at about the same altitudes. Each star will then give an error of the chronometer, and if the altitudes are rightly observed, the same error of the chronometer. If the errors do not agree, a mean will come nearer to the truth than either of them separately; but if the stars have not the same polar distance, the effect of a given error in altitude upon the hour angle must be computed for each, and the difference between the chronometer's errors divided in this ratio. Thus, suppose the eastern star gives a chronometer error of $25^s.0$ fast, and the western star an error of $28^s.0$ fast, while an error of $1'$ in the altitude of the eastern star causes twice the error in the deduced hour angle that a similar error of $1'$ does in the western star; the concluded true error should be $27^s.0$, instead of the mean error $26^s.5$. The reader will see that if the observations are made at exactly the same altitude, any mistake as to the index error, refraction, or any instrumental defect, is thus got rid of without much trouble. But, as has been mentioned before, very perfect observations of stars with reflecting instruments can scarcely be made unless the instrument is mounted on a stand. From good sets of observations of a star east and a star west, the time may be determined to $0^s.3$ or $0^s.4$. The time is required to reduce circum-meridian observations to the meridian for finding the latitude, and again the latitude is required in order to deduce the time from altitudes. An approximate latitude, such as results from the largest observed altitude about the meridian, will give the time near enough for the reduction to the meridian, and then the time may be computed rigorously with the exact latitude. Provision may be made for this revision by taking out the differences of the logarithms at each step of the first computation; but generally speaking, when the altitudes for time are taken near the prime vertical, as they ought to be, a small error in the latitude has so little effect on the hour angle, that the approximate latitude is near enough.

Determination of Greenwich Time astronomically.—1. There are two phenomena which are seen at the same moment from whatever part of the earth they are visible, namely, a lunar eclipse and the eclipses of Jupiter's satellites. The first was the only phenomenon from which longitudes were derived previous to the invention of telescopes, but it is not of frequent occurrence, and unfortunately cannot be noted very exactly. It has been proposed to measure equal quantities of the eclipse on each side of the middle, and formerly astronomers were very careful to note the moments when the umbra touched or covered well-defined spots. But at present, lunar eclipses are scarcely regarded, as there are many more accurate means of determining the longitude, and of more frequent occurrence; and lunar eclipses are of no value in the theory of the moon's motions. The eclipses of the satellites of Jupiter, especially of the first satellite, are much more common, and have been of great use in modern geography. The time at which the eclipses take place, that is, when the satellite, passing into the shadow of Jupiter, is lost (immersed), or passing out of the shadow, becomes visible (emerges), are set down in the 'Nautical Almanac' at the time they would be seen at Greenwich if visible. The observer at any other place notes when this phenomenon does actually happen at the place of observation, and the difference between the two times is the longitude of the place from Greenwich; east if the time of the eclipse is later than at Greenwich, and west if it be earlier. Unfortunately this method, so easy in practice, is by no means as accurate as it might at first sight appear. The theory of the satellites is scarcely to be considered as perfect, but this objection might be obviated by comparing corresponding observations, and might be very much diminished by correcting the predictions of the 'Nautical Almanac' by observations made at Greenwich, or any other well known place, about the same time. But the phenomenon is a gradual and not an instantaneous one, and the appearance or disappearance of the satellite varies greatly with the goodness of the telescope, the eye or mood of the observer, the

* There are tables for this purpose in Schumacher's 'Hülfsstafeln,' and in many sets of tables.

atmosphere at the place of observation, &c., so that a longitude deduced from an eclipse of the first satellite may be considerably wide of the truth. With ordinary telescopes we believe that eclipses of the second satellite are more than twice as uncertain as the first, and that the third and fourth satellites are not worth observing for this purpose, being much inferior to good lunar distances. A large mass of eclipses of Jupiter's satellites made by the same telescope and the same observer, and where the immersions are nearly as numerous as the emersions, will however yield a satisfactory result. The aperture of the object-glass employed, and also the sight of the observer, should correspond as nearly as possible with the telescope and observer at Greenwich, or whatever place is adopted as a standard of comparison. It is not considered advisable to use a smaller telescope than an achromatic of $2\frac{3}{4}$ inches aperture for this purpose, or one larger than of $3\frac{1}{4}$ aperture.

2. The time at Greenwich is most accurately determined by solar eclipses or occultations of fixed stars by the moon. The computations are rather long, but not very difficult or abstruse. The beginning and end of the solar eclipse should be observed; the latter is the better marked phenomenon, and if the eclipse be annular, the commencement and breaking up of the annulus. Recent observations have shown that these appearances are not instantaneous, and therefore that longitudes deduced from them are not free from uncertainty. The occultation of a fixed star by the moon is not liable to this objection; and when the star is bright, and both immersion and emersion can be carefully observed, the longitude from an occultation affords perhaps the best determination possible of the longitude between two distant places. Yet even here doubts may arise, at least in some cases. The star may be occulted too early by a lunar mountain, or disappear too late in a lunar valley. The occultation should be observed at both places, which is not often possible, and the star should pass not far from the centre of the moon. If the solar eclipse or the occultation be not observed at Greenwich, or at any well determined observatory, the data of the 'Nautical Almanac' must be corrected by the meridian observations of the moon about the time. The tables of the sun are at present nearly as perfect as observation can make them, but the moon may be out $15''$, or even $20''$, which might occasion an error of 30^s or 40^s in the deduced longitude, or from an eighth to a sixth of 1° . The solar eclipses, &c., with a map showing in what parts of the globe they are visible, are given in the 'Nautical Almanac,' and the occultations by the moon of all fixed stars to the sixth magnitude inclusive, visible at Greenwich, are also predicted to the nearest minute, with such a description of the relative situation of moon and star as will enable any one to observe them without difficulty. All possible occultations of fixed stars to the fifth magnitude inclusive, visible anywhere, are also set down in that valuable work, with the data necessary for determining whether they are visible at any specified place. We cannot press too earnestly on all persons interested in perfecting geography, the absolute necessity of learning to observe an occultation, and to take altitudes methodically with a circle or sextant. The computations may be made at home.

The transits of Mercury over the sun are rare, and the longitudes derivable from them not very accurate.

3. A good and now fashionable method of determining the longitude is by observing with a transit instrument the meridian passage of the moon's bright limb, and of stars which are near her parallel of declination. The 'Nautical Almanac' contains a list of the stars proper to be observed with the moon, and also the variations of the moon's R. A. in one hour of longitude, for computing the longitude.* When the place of observation is tolerably near Greenwich, the computation is very simple, that is, if the transit is nearly in the meridian and the moon is observed all over the wires. The error of the chronometer is taken from the neighbouring stars, and the transit of the moon corrected for this error, and for the rate, if sensible. If the place be to the east of Greenwich, the R. A. of the moon is less; if to the west, the R. A. is greater than at Greenwich. Taking the difference between the R. A. at the place and at Greenwich, and dividing by the variation in one hour of longitude, you have the longitude of the place E. or W. in hours and decimals of an hour. But this result requires correction when the corresponding observations at Greenwich, Cambridge, Edinburgh, &c., can be procured; for the R. A. of the moon may be erroneous more than $1^s.0$ from the imperfection of the lunar tables. By using the R. A. of the moon and stars observed at Greenwich, the longitude will not be affected by the errors of the tables. It is pretty much the same thing, and at times more convenient, to let the former computation stand, and to compute the longitude of Greenwich, Cambridge, &c., from the observations respectively

* These data might perhaps be further extended with advantage. Suppose the R. A. of the moon's bright limb on the meridian of Greenwich to be m ; on the meridian of any other place the longitude of which is required, m' ; the longitude of the place to be l , + when west, and - east; then m' can be thus expressed; $m' = m + a l + b l^2 + c l^3 + d l^4$, where a , b , c , and d can be previously computed, l being in decimals of a day. The approximate value of l , from the first term, $= \frac{m' - m}{a}$. Substituting this value for l , let the sum of the

other terms $= s$, then the exact longitude $= \frac{m' - m}{a} - \frac{s}{a}$.

made there, taking care to note the signs of the resulting longitudes. Then if the longitudes of the known and of the unknown place are both east or both west, the difference will be the true longitude of the unknown place, east or west of the known one. Some telescopes give a larger image of the moon than others, and its apparent diameter is affected by varying the aperture of the object-glass. The resulting errors in the longitude are got rid of by observing the second limb as often, if possible, as the first, and then, keeping the results separate, by taking a mean of the two. There is a mistaken notion among many observers, that there is no need to care for the position of the transit. Now any considerable error in the position of the transit does occasion an equivalent error in the longitude, and though it can be corrected, if there are data for determining the want of adjustment, this gives some trouble in the computation. It is so easy to place a transit very nearly in the meridian, and to adjust it in every respect, at least approximately, that there is no excuse for carelessness in this respect. The observer should always take the transits of a star near the pole, and of all Greenwich stars above and below the moon which pass about the time of her culmination, and it is proper to reverse the instrument on alternate nights. When the place of observation is very distant from Greenwich, it will be necessary, until the quantities a , b , c , d , mentioned in the note, be computed, to take a little more trouble. The approximate longitude is calculated as before, and then the R. A. of the moon's bright limb must be computed for the corresponding Greenwich time, from the R. A. of the moon for every hour; the moon's semi-diameter in R. A. must also be computed. We have found it on the whole most intelligible, and therefore most safe, to compute the R. A. of the moon's bright limb on two hypotheses of longitude, one the minute above and the other the minute below the approximate value. These results are to be corrected by the Greenwich or other observations for the error of the lunar tables, and then, by simple proportion, the correction is determined for one of the hypothetical longitudes. This is rather a long process, but it is strictly accurate, and the steps are intelligible as the computer proceeds. The method of determining the longitude by transits of the moon and stars is the best for places very distant in latitude or longitude, where the same occultations cannot be seen. It is nearly as good for the most distant as the nearest place, the variation of the error of the lunar tables being the only additional cause of inaccuracy, and the phenomenon presents itself very often. It does however require a very nice and well fixed instrument and a careful observer, as 1° error in observing the R. A. of the moon will cause an error of nearly 30° in the resulting longitude, or $\frac{1}{3}$ of a degree. A considerable mass of observations of both limbs corrected by corresponding observations will scarcely be more than 2° or 3° wrong.

4. But where a transit instrument cannot be carried, or cannot be used, as at sea, the longitude must be found *astronomically* by the distance of the moon from the sun, planets, or fixed stars, measured with a reflecting instrument. This apparent distance is reduced to the true distance, that is, such as it would be, seen from the centre of the earth, and as these distances are computed and set down in the 'Nautical Almanac' for every three hours Greenwich time, as they would be seen from the same place, the Greenwich time corresponding to the time of the observation can be calculated. But the time at the place is always supposed to be known from observation, and hence the difference gives the longitude. The longitude may be determined on shore by lunar observations, and, if a stand be used, with much greater accuracy than at sea. All ships and travellers ought to be well supplied with chronometers, that is, the means of keeping their Greenwich time when by observation they have got it, and then the result of the observation and computation is simply stated to be the error of the chronometer on Greenwich time. The chronometer, if the rate be pretty well known, continues to give the Greenwich time (the correction for error and rate being applied) for several days; and the longitude is found every day, by comparing the actual time at the place of observation with the Greenwich time at the same moment, given by the chronometer. We have spoken as if one chronometer alone were used, but it is mere folly to rely upon one or even two chronometers in a ship, or in important geographical researches.* These are to be compared from day to day, to ascertain that they are not suddenly altering their rates, and also whenever any astronomical observation is made which determines the Greenwich time (for that gives the error of each of the chronometers), or the time at the place. In reducing observed lunar distances to the true lunar distances, the altitudes of the sun and moon, or moon and stars at the time of observation are required, and at sea two observers are commonly set to measure these altitudes at the moment the lunar observer gives a signal that he has made the

* In the first place chronometers are liable to accidents, and secondly, to change their rates, and that sometimes by jumps. With two chronometers evidence is given of error by their discrepancy, and with three, the faulty chronometer may be detected. The best two-day box-chronometers may be bought for forty guineas, and the best gold and silver pocket-chronometers for forty and thirty guineas respectively. There is an idle opinion that chronometers are not good pocket-watches. They are perhaps a little more liable to injury when *let fall*, than other watches, on account of the heavy compensated balance, but after wearing chronometers for years without any particular care, we believe that three good pocket-chronometers, not larger than common watches, will keep the time for a month, as well as it can be got by lunar distance.

contact; indeed a fourth person is sometimes engaged in noting the chronometer. On shore this profusion of aids cannot always be obtained, nor are they at all wanted. If the time at the place and the latitude be known, the altitudes may be computed, or the observer may proceed thus: 1st, an altitude of the sun, planet, or star; 2ndly, an altitude of the moon's bright limb; 3rdly, three lunar distances; 4thly, a second altitude of the moon; and 5thly, a second altitude of the star or sun, noting the chronometer at each observation. He will then have the means, by simple proportion, of reducing the altitudes to what they would have been at the time of observing the lunar distances.

We should advise observers, who are properly furnished with chronometers, rather to make a large number of observations on a few favourable nights, than to take a few observations on many nights. By observing several lunar distances on both sides of the moon, and from all the stars and planets east and west given in the 'Nautical Almanac,' the errors of the instrument may be in a great measure eliminated, and the error of observation much diminished. It is evident that if two equal distances are taken, one east of the moon and the other west, then any error of the instrument, such as erroneous index error, want of parallelism in the glasses or telescope, excentricity, &c., would be the same in each, and therefore could be got rid of. In like manner, if two observations on the same side of the moon give different longitudes, it is clear that the instrument has some error which is *not* index error. On this subject we shall have occasion to speak again in treating of the sextant. The luni-solar observations are generally preferred by seamen (and they are perhaps the most satisfactory), partly perhaps because the altitude of the sun, by giving time at the place, is immediately applicable to the determination of the longitude. The longitude from lunar distances, however carefully taken, cannot be relied upon to very great nicety. With all appliances, a distance to 10", and a longitude to 20", or $\frac{1}{12}$ th of a degree, can scarcely be considered as certain, and the errors of the lunar tables will not unfrequently double this error. At sea it would not be safe to rely on any series of lunar distances for a less quantity than 1^m of longitude, or $\frac{1}{4}$ th of a degree, but this is quite sufficient for the purposes of navigation in open seas.

The computation of lunar distances is very easily performed by Thomson's tables, which are exceedingly convenient, and require only a little more extension. They are approximate, but near enough for the navigator and the traveller *en route*. As the last accuracy can only be given to the computations after the errors of the lunar tables are corrected, there is no need of much refinement in the previous work.

It has been proposed to determine the longitude on shore by taking altitudes of the moon with the mercurial horizon; and between and near the tropics the method may be a good one. In these low latitudes the motion of the moon in altitude is nearly vertical and very rapid, and this motion is doubled by observing the distance between the moon and its image seen by reflection. The bright edge of the moon is a good object in reflecting instruments. The calculation may be made thus: The time at the place must be most scrupulously determined, and the error and rate of the chronometer known, if possible, by equal altitudes of the sun on each side of noon and midnight. Then, the error of the chronometer being known at the place and time of observation, assume an approximate value of the longitude, and determine the Greenwich time, the R. A. and declination of the moon, and its apparent diameter and parallax. Each altitude of the moon will, when properly reduced, give an error of the chronometer, which, if the assumed longitude be correct, will agree with the error obtained by the sun or stars. If there be a difference, a second longitude may be assumed, and thus, as has been shown in speaking of transits of the moon, the terms may be obtained from which, by a simple proportion, the true longitude can be deduced. It is not improbable that the doubling the motion of the moon in observing by reflection, and the sharpness of the images, may make up for the error committed in ascertaining and keeping the time; but of this the observer must be the judge.

Determination of Greenwich Time by Chronometers.—Hitherto the Greenwich time has been extracted from astronomical phenomena, but where the distance is not great, the time may be brought from Greenwich by chronometers. Suppose, for instance, the longitude of Madeira were required: then, having ascertained the errors and rates of several good chronometers at Greenwich, they are carried to Madeira, and their errors on the meridian of Madeira, and their rates, determined there. The Greenwich time is known from each chronometer, supposing the rate during the voyage to be the mean of the rates before and after, and thus each chronometer gives a longitude of Madeira, and the mean of the whole is taken. The voyage back to Greenwich, in like manner, with the errors and rates on arriving at Greenwich, furnish a second longitude; and if the motion at sea has any tendency to alter the rates, this cause will affect the first determination with a certain error, while it affects the second determination with exactly the same error, but in a different sense. If it increases the difference of longitude one way, it diminishes it the other way. By a mean of several such voyages the difference of longitude of places within a week or perhaps a fortnight's journey may be ascertained with considerable exactness. There are some precautions to be adopted in determining longitudes chrono-

metrically, which ought not to be neglected. It is well known that two observers will sometimes differ several tenths of a second from each other in getting the time at the same place and with the same instrument. Now this *personal equation*, if it exist between the observers at the two places, will affect the longitude by exactly its amount: hence the observers should be reversed for half the time of the experiment, if possible, or their *relative personal equation* found by comparison with each other, or at least with a third person. The accuracy of a chronometrical longitude depends on the distance in time between the places compared and the smoothness of the conveyance. It is decidedly the best mode where the distances do not exceed three or four days' journey, and where there are good carriage-roads or steam-boats. At sea, for voyages of moderate length, the Greenwich time may be taken almost entirely from chronometers; and if the number be considerable, and the watches good, there is little occasion for lunar distances, except for the greater caution, and to be assured against any accident affecting all the timekeepers the same way.

Determination of Differences of Longitude by Rockets.—Another mode of ascertaining differences of longitude is that of conveying the time from one point to another by fire-signals or rockets. Thus, if a rocket is fired from a station between two observatories, and the explosion noted in the time proper to each place, the difference between the times will be the difference of longitude. A chain of such signals may be extended a considerable distance thus:—Let the two points to be connected be A and B, and let an observer with a chronometer be placed at a, and others with rockets at a, β , thus: A, a, a, β , B. Then the observers at A and B note the rockets from a and β in times of their respective observatories. The person stationed at a notes by his chronometer the rockets at a and β (suppose β at 10 minutes after a), and as he observes a at the same physical moment with A, A would see β , if it were visible, just 10 minutes later than he does actually see a, and therefore the explosion of β is known in time proper to A's observatory; but it is also seen by B at the same moment in his time, and therefore the difference of longitude is obtained. In like manner, any number of intermediate stations of observers and rockets may be interpolated between two distant points, A and B. The *relative personal equation of the observer at A and B* must be taken into account [EQUATION, PERSONAL] both as astronomers and observers of signals; but the personal equation of the intermediate observer does not affect the observation. In this way the longitude of Paris from Greenwich was determined. ('Phil. Trans.')

Determination of Differences of Longitude by Galvanic Signals.—The best method hitherto devised for determining differences of longitude, is founded on the transmission of signals by galvanic electricity. This method was first successfully practised in the United States of America. The most obvious mode of its application consists in despatching from one of the two stations to the other, a definite number of signals by the telegraphic wire, the observer at the one station recording the times of transmission of the signals, and the observer at the other station recording the times when they are received. The operation is then repeated by the transmission of signals from the second station to the first. The velocity of the electric fluid being supposed to be sensibly instantaneous, a comparison of the local times at the two stations will indicate their difference of longitude. The application of this method, which has been found to give the best results, consists in receiving the signals upon Saxton's recording apparatus.

Finally, the longitude and latitude of one place from another may be determined by measurements on the earth's surface, if the figure of the earth be sufficiently well known. The geodesical latitudes and longitudes are in many cases found not to agree with those found astronomically, owing, as it is supposed, to some variations in the density of the earth in the neighbourhood of the place of observation. It is however a convenient way of finding the latitude and longitude of points near a well-established observatory, and connected by trigonometrical survey.

Let the distance PG in feet and the bearing KGP of the point P from the observatory G be known by survey, and GN be an arc of the meridian. Then drawing PK a perpendicular to GN, $PK = PG \times \sin$ of

PK and $GK = PG \times \cos PK$, when PK and GK are known, in feet. Find the value of $\frac{1}{2} KG$ in seconds of latitude approximately by supposing 1" to be = 100.8 feet, and add or subtract this, as the case may be, to the latitude of G, which will give the latitude of M, the middle point; call this λ . Then the value in English feet of a degree of latitude at M is

$362747.7 + \text{number the logarithm of which} = \begin{cases} 3.5634881 \\ + 2 \log \sin \lambda \end{cases}$ and the value of a degree of longitude at the same parallel in English feet =

number, $\log = \begin{cases} 5.5625161 \\ + \log \cos \lambda \end{cases} + \text{number, log} = \begin{cases} 3.0863668 \\ + \log \cos \lambda \\ + 2 \log \sin \lambda \end{cases}$

With these values of a degree of latitude and longitude the distances GK and PK are readily converted into arcs of latitude and longitude.

On this subject the reader may consult the article GEODESY, and the 'Encyclopædia Metropolitana,' art. 'Figure of the Earth.'

The solution of the problems assumed to be known in the foregoing article may be found in all treatises on astronomy and in most collections of tables of navigation. We have recommended Thomson's 'Tables' as very convenient, and sufficiently accurate for the traveller and navigator, but any tables and methods which a man has become accustomed to will do. It would require too much space to give reasons and explanations for the opinions here advanced, but we will give two or three recommendations which few observers will regret to have followed. The first is to make, when practicable, large masses of careful and unhurried observations, and especially to observe the rules given above for nullifying instrumental error, by making such observations that a given error will have contrary effects in the result. Secondly, to be very careful in selecting their instruments and their timekeepers, which should come from good makers, and be carefully tried before starting, especially at such temperatures as the traveller may expect to meet with. A chronometer which is excellent for a polar expedition may be an indifferent watch on the Tigris or in the interior of Africa, and *vice versa*. For any overland expedition three pocket chronometers should at least be taken, and the number must be increased according to the length, the difficulty, and the importance of the journey, and a liberal allowance made for stoppages, changes of rate, accidents, &c.: a belt of half a dozen chronometers would scarcely be felt to be an inconvenience. Lastly, if the traveller's object be chiefly that of determining exact positions, he should be careful to determine the longitudes of all his principal points by solar eclipses or occultations of fixed stars by the moon, if he cannot carry and fix a transit. At these points he should determine the rates of his chronometers for a new departure, and determine as much of the country as circumstances will allow by journeys of ten days or a fortnight, returning to the same place. When the principal points are well fixed (we speak of longitudes, for good latitudes may be got with almost any instrument, or by any person), the chronometers will fix every halting-place where the time is observed, and this may be got in a few minutes any fine night or morning or afternoon; and then the itineraries, compass bearings, marches, &c., and all the loose information on which too much of our geography is founded, will furnish valuable details in the proper place. The necessary apparatus is not very expensive or cumbersome, and with a little practice can be managed by a moderately intelligent and methodical person.

LOOM. [WEAVING.]

LOPHINE ($C_{12}H_{10}N_2$) is one of the bases derived from the oil of bitter almonds. It is formed when benzoline is distilled. Ammonia is given off, and lophine is left undissolved. It is soluble in alcohol with acids, and precipitated again by ammonia. It occurs in the form of fine silky crystals, and forms salts with acids, which are however not very stable.

LORD ADVOCATE OF SCOTLAND. This is the peculiar appellation of the senior standing counsel for the crown in Scotland. The regular series of such officers cannot be carried to an earlier date than the end of the 15th century. Previous to that time, indictments seem to have been under the superintendence of the clerk of court, or justice clerk [JUSTICE CLERK]; and for prosecutions before the parliament, we find sometimes the chancellor, sometimes the clerk-register, and at other times a special counsel for the crown.

The earliest standing "Advocate," and with whom the series properly begins, was Sir John de Ros of Mountgreenan, in the county of Ayr, an individual well known both in the politics and literature of his time, and one of the poets commemorated by Dunbar. When the Court of Session was erected, Sir Adam Otterburn of Auldham was king's advocate, and was not only privileged to plead within the bar, but actually nominated one of the judges of the court. It was from this circumstance he acquired the style of Lord Advocate (Pitcairn's *Criminal Trials*, Stat. 1587, c. 115.). In 1610, he had the additional style of "Right Honourable." (Act of Sederunt, 17th Nov., 1610.) It was, however, in the time of Sir Thomas Hope (founder of the noble family of Hopetoun, and others) that the office acquired the vast political importance which has in modern times belonged to it. This arose not less from the subtle and ambitious character of that famous person, than from the circumstance of the king's removal to the throne of

England, and the consequent remoteness of Scotland from the immediate seat of government.

It is difficult to define the powers and duties of the lord advocate; they are said to be indefinable. The most prominent however is that of public prosecutor; and in this capacity he has, besides the solicitor-general, four standing deputies of his own appointment, who retire with him on a change of ministry. These deputies assist him in the Court of Justiciary, and are despatched by him to the several circuits of that court to prosecute indictments there. He has also a deputy in the Court of Exchequer; and a deputy or occasional substitute to conduct prosecutions before the sheriff of Edinburgh, or other county courts. Every county court has indeed a "procurator fiscal," whose duty it is to sue on behalf of the crown in his county; but that officer is not yet placed on a proper footing, being neither of the bar, nor named by the crown or the lord advocate.

LORD-KEEPER (*Custos magni Sigilli*), an ancient officer of the crown, who had the custody of the king's great seal, with authority to affix it to public documents, some of the most important of which can only be authenticated in this formal manner.

Until the reign of Henry III. the office of keeper of the great seal appears to have been distinct from that of chancellor, and generally subordinate to it. The chancellor, as a high judicial officer, was sworn at his entrance upon his duties, but the functions of the keeper being considered as chiefly ministerial, no oath appears to have been required from him. The chancellor was often elected by the baronage parliament, or great council of the nation, but the custody of the great seal was under the control of the king. The ancient entries respecting the appointment of the chancellor generally are—A. B. Cancellarius (or in Cancellarium) Angliæ electus, or a baronagio, or in pleno parlamento, or per regem et parlamentum, constitutus est. Records of the reign of Henry I. and John show that both offices were held simultaneously by different persons under those princes. Sometimes the offices were united in one individual, who was thus both judge and minister. In 11 Henry III., Ralph Nevill was appointed by parliament chancellor for life; and two years afterwards he received the custody of the great seal from the king. In 22 Henry III. the great seal was forcibly taken from Nevill by the king, who delivered it to two persons, Geoffrey the Templar and John Lexington; but as Nevill could not be deprived of his judicial authority by the crown, he continued to hold the office of chancellor until his death. But the great seal was under the control of the chancellor; and when Henry III. demanded it from the Bishop of Chester, his chancellor, he answered, that having received the seal by the common council of the realm, he could not resign it to any one without the like common consent. It was matter of complaint against Henry III. that in 1261 he appointed Walter de Merton to be chancellor, "inconsulto baronagio," or without the consent of the baronage. In the following year he appears to have removed Hugh le Despencer the chief-justice, and Nicholas de Ely the chancellor, appointed by the barons.

Edward I. took the great seal with him into Flanders, and afterwards into Gascony, leaving his chancellor in England with a temporary seal: and in 6 Edward I. the Bishop of Bath and Wells, the chancellor, on going abroad left the great seal in the custody of Sir John de Kerby, with an injunction to despatch the business of the chancery in his absence. The chancellor cannot now make a deputy, or, as he was formerly called, a lieutenant. In 16 Edward I., Ayremin, master of the rolls, and his companions, were keepers of the great seal; Burnell, bishop of Bath and Wells, being at the same time chancellor. Among the restrictions imposed on Edward II. by the ordinance elected by the barons and commons in parliament, was one that the king should appoint the chancellor and certain other great officers by the advice and assent of his baronage, and in parliament. This seems to have been the last interference with the royal authority over the appointment of chancellor until the time of the Long Parliament. In the more vigorous reign of Edward III. we find by the parliament roll that in 1343 the commons prayed that no alien might be made chancellor, but the king answered, that he could appoint whom he would. Henry V. had two great seals, one of gold, which he delivered to the bishop of Durham, making him *lord chancellor* of England, and another of silver, which he delivered to the bishop of London to keep. The statute 31 Henry VIII., c. 10, assigned the same rank to the lord chancellor and the lord-keeper, giving to the person holding the one office or the other precedence over all lay peers, except those of the blood royal; and in 5 Elizabeth, c. 18, Sir Nicolas Bacon, lord-keeper, procured an Act which, after reciting that some question had of late arisen whether like place, authority, and power belonged to the office of lord-keeper of the great seal of England, as belonged to the lord-chancellor of England, declares that the keeper of the great seal has always had, used, and executed the same place, authority, pre-eminence, jurisdiction, execution of laws, and all other customs, commodities, and advantages as the lord-chancellor.

Notwithstanding these two statutes the appointment of lord-keeper appears not to have stood so high in the estimation of the public as that of chancellor; and the great seal has been generally delivered with the latter title.

Upon the rupture between Charles I. and his parliament the king took the great seal to Oxford, upon which a new seal was ordered to be made by the parliament. This measure was the subject of severe

reproaches from the royalists; though unless the parliament were prepared to submit unconditionally to the king, it is difficult to say how any other course could have been adopted.

(Matth. Paris; *Parliament Rolls*; Coke's 4th *Inst.*; Bohun's *Cur-sus Cancell.*)

The power and duties of the lord-keeper, as identified with the chancellor, have already been stated. [CHANCELLOR; CHANCERY.]

LORD-LIEUTENANT. It was formerly usual for the crown, from time to time, to issue commissions of array, requiring certain experienced persons to muster and array the inhabitants of the counties to which such commissioners were sent. They were directed to put into military order those who were capable of performing military service, and to distrain such as were not qualified to serve, but were possessed of real or personal property, to furnish armour to their more vigorous countrymen; and they were to erect beacons where necessary. The form of these commissions, after much complaint, was settled by statute, and may be seen at length in the Parliament-rolls of 5 Hen. IV., 1403-4.

In the 16th century these commissions appear to have given place to commissions of lieutenancy, by which nearly the same powers were conferred on certain persons as standing representatives of the crown. In 1545 a commission "de arraiaione et capitaneo generali contra Francos" issued to the duke of Norfolk, constituting him the king's lieutenant, and captain-general of all captains, vice-captains, men-at-arms, armed men, archers, and all others retained or to be retained against the French, in the counties of Essex, Suffolk, Norfolk, Hertford, Cambridge, Huntingdon, Lincoln, Rutland, Warwick, Northampton, Leicester, and Bedford. A similar commission issued to the Duke of Suffolk for the counties of Kent, Sussex, Surrey, Hants, Wilts, Berks, Oxford, Middlesex, Bucks, Worcester, and Hereford, and London; and to John Russell, knight, Lord Russell, keeper of the privy seal, for the counties of Dorset, Somerset, Devon, Cornwall, and Gloucester. (Rymer.) These officers are however spoken of by Camden, in the reign of Elizabeth, as extraordinary magistrates, constituted only in times of difficulty and danger, which was the case with commissioners of array, as appears from the recitals in their commission.

The right of the crown to issue commissions of lieutenancy was denied by the Long Parliament, and formed a proximate cause of the rupture between Charles I. and his subjects. Upon the Restoration the right of the crown to issue such commissions was established by a declaratory Act, 14 Charles II., cap. 3.

The authorities and duties of the lord-lieutenant and of his temporary vice-lieutenants, and of his permanent deputy-lieutenants, have with reference to military affairs been regulated by the Militia Acts. [MILITIA.] The lord-lieutenant, however, nominates to the Lord Chancellor, all the justices of the peace for the county of which he is lieutenant.

LORD OF MISRULE, the master of the revels at Christmas in any nobleman's or other great house. "First in the feast at Christmas," says Stowe, 'Survey of London,' "there was in the king's house, wheresoever he was lodged, a Lord of Misrule, or master of merry disports, and the like had ye in the house of every nobleman of honour or good worship, were he spiritual or temporal; amongst the which the mayor of London, and either of the sheriffs, had their several Lords of Misrule, ever contending, without quarrel or offence, who should make the rarest pastimes to delight the beholders. These lords, beginning their rule on Alhallow-eve, continued the same till the morrow after the Feast of Purification, commonly called Candlemas-day: in all which space there were fine and subtle disguisings, masks, and mummeries, with playing at cards for counters, nailes, and points in every house, more for pastime than for gain."

This lord of Misrule, or revel-master, was sometimes termed a Christmas prince. Warton, in his 'History of English Poetry,' tells us that in an original draught of the statutes of Trinity College at Cambridge, founded in 1546, one of the chapters is entitled, 'De præfecto Ludorum, qui Imperator dicitur,' under whose direction and authority Latin comedies and tragedies are to be exhibited in the hall at Christmas; as also "sex spectacula," or as many dialogues. With regard to the peculiar business and office of Imperator, it is ordered that one of the Masters of Arts shall be placed over the juniors every Christmas, for the regulation of their games and diversions at that season of festivity. His sovereignty was to last during the twelve days of Christmas, and he was to exercise the same power on Candlemas-day. His fee was forty shillings. In an audit-book of Trinity College in Oxford, for the year 1559, Mr. Warton found a disbursement "pro prandio Principis Natalicii." A Christmas prince or lord of misrule, he adds, corresponding to the imperator at Cambridge, was a common temporary magistrate in the colleges at Oxford. The law societies of London had similar commemorations, and in 1635, the expenses of the Master of the Revels in the Middle Temple amounted to 2000*l.*, paid from his own purse, and when he was deposed, or his term of office had expired, he was knighted by the king. After 1640 we hear nothing of the Lord of Misrule in England.

In Scotland, where the Reformation took a more severe and gloomy turn than in England, the "Abbot of Unreason," as he was there called, and other festive characters, were suppressed by the legislature as early as 1555. At Rodez, the capital of the province of Rovergne in France, previous to the Revolution, they had an "Abbé

de la Malgouverné," who corresponded exactly with our Lord of Misrule.

LORDS, HOUSE OF, one of the constituent parts of the Parliament of the United Kingdom. [PARLIAMENT.] The other is the House of Commons.

The persons who sit in the House of Lords are the Lords Spiritual and Lords Temporal.

Before the Reformation, when the monastic establishments which abounded in England were suppressed, the superiors of many of them, under the names of abbots and priors, sat as Lords Spiritual in this assembly. In those times the Lords Spiritual equalled, if they did not outnumber, the Lords Temporal who sat at any given time in Parliament; though now they form only about one-thirteenth of the persons composing this assembly. Six more bishops were added when the abbots and priors were removed.

The Lords Temporal are all the peers of England, being of full age, and not incapacitated by mental imbecility; sixteen representative peers of the Scottish peerage, and twenty-eight representatives of the Irish peerage. The number of the Scotch and Irish representative peers is fixed by the acts of union with Scotland and Ireland in 1707 and 1800 respectively; but the number of peers of England is perpetually varying, and depends upon the casualties of minorities, and on the will of the sovereign, who can make any man a peer. In June, 1860, it consisted of 3 princes of the blood royal, 3 archbishops (one being an Irish representative), 20 dukes, 21 marquises, 111 earls, 22 viscounts, 24 English bishops, and 3 representative Irish bishops, and 214 barons, besides the Scotch and Irish representative peers.

The component parts of this assembly may be thus classified:—1. Persons sitting there in respect of offices held by them. Such are the spiritual lords of England. 2. Persons who sit in right of inheritance of a dignity of peerage. 3. Persons who have been created peers. 4. Hereditary peers of Scotland (for there can be no creation of peers of that part of the United Kingdom) elected by the whole body of the Scottish peerage to represent them in parliament, at the beginning of every parliament. 5. Hereditary or created peers of Ireland, elected by the whole body of the Irish peerage; they sit for life, and vacancies are supplied as they occur. Irish peerages can be created in the proportion of one for every three becoming extinct. And 6. Spiritual lords of Ireland, who sit in turns according to a cycle established by 3 Will. IV. c. 37. The great body of the house however consists of hereditary Lords Temporal of England, under the several denominations of dukes, marquises, earls, viscounts, and barons. Each of the individuals of these ranks has an equal vote with the rest; but they sit in the house in classes, and according to their precedency.

The only material changes which have been made in the constitution of this assembly in the long period of its existence have been: 1. The supposed limitation of the right of all holding lands in chief of the crown to sit therein, by king Henry III. after the battle of Evesham. 2. The removal from it of representatives of the counties, cities, and boroughs, who are supposed to have formerly sat with the lords, and the placing them in a distinct assembly, called the House of Commons. 3. The reduction in the number of the Lords Spiritual, by the suppression of the monastic establishments. 4. The introduction of the Scottish representative peers. And 5. The introduction of the Irish bishops and the Irish representative peers.

This house may be traced to the very beginning of anything like an English constitution. It is in fact the *magnum concilium* of the early chronicles. The bishops are sometimes said to sit there in virtue of baronies annexed to their respective offices; but it is questionable whether baronies are attached to the bishoprics of the new creation by Henry VIII.; and at best it is but a legal fiction, it being evident from the whole course of history that the bishops formed, as such, a constituent part of such assemblies in the Saxon times, and were, as such, among the chief advisers of the king. One of the last acts of King Charles I., before he finally left London and disconnected himself from the Parliament, was to give the royal assent to a bill for removing the bishops from Parliament. The bishops were restored after the return of Charles II., 1660.

A question has been raised whether, as the Lords Spiritual and the Lords Temporal, though sitting together, form two distinct *estates* of the realm, the concurrence of both is not requisite in any determination of this house, just as the consent of the two houses of Parliament is necessary to every determination of parliament. But it is now understood that the Lords Spiritual and Lords Temporal are one body, whose joint will is to be collected by the gross majority of voices: and statutes have been made in the absence of all the Spiritual Lords.

The House of Lords has two distinct functions: the legislative and the judicial.

In its legislative character, every new law, and every change in the existing law, must have the consent of a majority of this house, as well as of a majority of the House of Commons.

In its judicial character, it is a court for the trial—1. Of criminal cases on impeachment by the House of Commons; 2. Of peers, on indictments found by a grand jury; 3. For the hearing and determining of appeals from decisions of the Court of Chancery; 4. For the hearing and determining of appeals on writs of error to reverse judgments of the Court of Exchequer Chamber (which is itself a court of

appeal from the courts of Common Law); and 5. In hearing and determining appeals from the supreme courts in Ireland and Scotland. The House can require the attendance of the judges of the superior courts of law, to assist it in the discharge of its duties; which is sometimes done.

A few points in which the House of Lords differs from the lower house of Parliament remain to be noticed. In the chair of the house sits the lord high chancellor of England. When the king goes to Parliament he takes the throne in the House of Lords, and the Commons are summoned to attend him there to receive the communication of his will and pleasure. The royal assent to bills, whether given by the sovereign, in person, or by a commission appointed by the king or queen, is given in the House of Lords. All bills which affect the rights and dignities of the peerage must originate in that house. The members of the House of Lords have a right of voting on any measure before the house by proxy, but the proxy must be a member of the house; and, lastly, they have the privilege of entering on the journals of the house their dissent from any measure which has received the sanction of the majority, with the reasons for that dissent. This is called their protest. For further information see PARLIAMENT.

LORDSHIP. [LEET.]

LOTIONS, or washes, termed also epithems, and when intended for the eye, collyria, or eye-washes, are either mixtures of different ingredients, or solutions of various medicinal substances, in water or other menstrua, designed for external application. If the object be to reduce the temperature of a part, they are generally formed of spirituous or other volatile principles, which by their evaporation occasion cold (and such must be applied by means of a very thin single layer of linen); or of saline bodies, which at the moment of their solution cause a reduced temperature, and which should be applied immediately after being mixed, and frequently renewed. Others are composed of stimulating substances, and are intended to impart power to indolent tumours or ulcers, while a different set are designed to allay pain, and are composed of sedative or narcotic principles.

Many of the nostrums sold under the name of lotions are solutions of very active ingredients, and their application is often productive of very serious effects.

LOTTERIES have been encouraged by some states for the purpose of raising a revenue. The general plan has been for the government to sell a certain number of tickets or chances, and to distribute by lot a part of the money thus collected as prizes among a comparatively small number of the purchasers. Lotteries are games of chance, the aggregate number of players in which are sure to lose a part of their venture. During the period in which the English state lotteries were carried on by Act of Parliament, it was the plan to distribute in prizes of different magnitudes an amount equal to 10% for each ticket or chance that was issued, and the profit to the state consisted of the sum beyond that rate which contractors were willing to give for the privilege of selling to the public the tickets or shares of tickets, which for that purpose they might divide into halves, quarters, eighths, and sixteenths of tickets. The price paid by the contractors for this privilege varied with circumstances, but was usually about six or seven pounds per ticket beyond the amount repaid in prizes, while the price charged by the contractors to the public was generally four or five pounds per ticket beyond that paid to the government; and more than this rate of advance was always required when the tickets were divided into shares, the smaller shares being charged more in proportion than the larger.

The earliest English lottery of which there is any record was in 1569, when 40,000 chances were sold at ten shillings each: the prizes consisted of articles of plate, and the profit was employed for the repair of certain harbours. In the course of the following century the spirit of gambling appears to have materially increased in this direction, for *private* lotteries were, early in the reign of Queen Anne, suppressed "as public nuisances." In the early period of the history of the National Debt of England, it was usual to pay the prizes in the state lotteries in the form of terminable annuities. In 1694 a loan of a million was raised by the sale of lottery tickets at 10% per ticket, the prizes in which were funded at the rate of 14 per cent. for sixteen years certain. In 1746 a loan of three millions was raised on 4 per cent. annuities, and a lottery of 50,000 tickets at 10% each; and in the following year one million was raised by the sale of 100,000 tickets, the prizes in which were funded in perpetual annuities at the rate of 4 per cent. per annum. Probably the last occasion on which the taste for gambling was thus encouraged was in 1780, when every subscriber of 1000% towards a loan of twelve millions at 4 per cent. received a bonus of four lottery tickets, the value of each of which was 10%.

In 1778 an Act was passed obliging every person who kept a lottery-office to take out a yearly licence, and to pay 50% for the same, a measure which reduced the number of lottery-offices from 400 to 51.

By limiting the subdivision of chances to the sixteenth of a ticket as the minimum, it was intended to prevent the labouring population from risking their earnings, but this limitation was extensively and easily evaded by means which aggravated the evil, the keepers of these illegal offices (commonly known as "little goes") and insurance offices requiring extra profits to cover the chances of detection and punishment. All the efforts of the police were ineffectual for the suppression

of these illegal proceedings, and for many years a growing repugnance was in consequence manifested in parliament to this method of raising any part of the public revenue. At length, in 1823, the last Act that was sanctioned by parliament for the sale of lottery tickets contained provisions for putting down all private lotteries, and for rendering illegal the sale, in this kingdom, of all tickets or shares of tickets in any foreign lottery, which latter provision is, however, to this day, extensively evaded.

The system of state lotteries was very long carried on by the French government, and was the cause of still greater demoralisation than in England. State lotteries have been abolished in France. Lotteries for the purpose of raising money for state purposes are still carried on in the Austrian dominions, in several of the smaller German states, and by the government of the Pope. The issuing or dealing in tickets for foreign lotteries in the United Kingdom is punishable as a misdemeanour.

Lotteries have been very common in the United States, and have been sanctioned by the several states, not so much as a means of raising money for state purposes, as with the view of encouraging, as they supposed, many useful objects which could only be effected by raising at once a large sum of money, such as canals, the establishment of schools, and even the publication of a book. The numerous frauds practised in lottery schemes in the United States have perhaps done more to open the eyes of the people to the mischief resulting from them than any investigation into the true principles of lotteries. A distinguished American lawyer, who figured in the New York State Convention nearly fifty years ago, declared that though "he was no friend to lotteries, he could not admit that they were *per se* criminal or immoral, when authorised by law. If they were nuisances, it was in the manner in which they were managed. In England, if not in France, there were lotteries annually instituted by government, and it was considered a fair way to reach the pockets of misers and persons disposed to dissipate their funds. The American Congress of 1776 instituted a national lottery, and perhaps no body of men ever surpassed them in intelligence and virtue." These remarks are merely quoted in order to show what a man of high character in America for integrity and knowledge thought of lotteries. The opinions which he expressed were at that time shared by a great number, and lotteries are still common in the United States, as the advertisements in their papers show.

The lotteries called Art-Unions are noticed under ART-UNIONS.

LOUIS, or LOUIS D'OR, a gold coin in the old system of France, first struck under Louis XIII., in 1641. Kelly says, "Louis d'ors coined before 1726, which passed then for 20 livres, were coined at the rate of 36½ per French mark of gold, 22 carats fine; the remedy in the weight was 14 grains per mark, and the remedy in the alloy one-fourth of a carat. These ceased to be a legal coin in France as far back as 1726; but they still continued to circulate through many parts of Germany and Switzerland, where they had a fixed value, and were known by the name of the old Louis d'ors." Upon the return of the Bourbon family, in 1814, the twenty-franc pieces struck by Louis XVIII., in imitation of the Napoleons, received the name of Louis, or Louis d'or; a designation which is likewise given occasionally to the same coin struck by king Louis Philippe, but which are more ordinarily called twenty-franc pieces. Both have been discontinued, and replaced by the Napoleon.

The old ecus, coined before 1726, were called Louis blancs, and Louis d'Argent.

LOXODROMIC SPIRAL (λοξός, oblique, δρόμος, course), the curve on which a ship sails when her course is always on one point of the compass. It is called in English works the RHUMB LINE.

LUCERN (*Medicago sativa*), a plant of the Linnaean class Diadelphia and order Decandria, with a papilionaceous flower, and of the natural family of the Leguminosæ. There are many species of the *Medicago*, of which one is super-eminent as an artificial grass in temperate climates, and a most valuable plant for feeding cattle. It was in high repute among the ancients. The authors *De Re Rustica* speak of it with enthusiasm, and all over the continent of Europe, wherever husbandry has made any progress, it is in high reputation. Lucern is a plant which will not bear extreme frost nor superabundant moisture, and its cultivation is therefore restricted to mild climates and dry soils; but, where it thrives, its growth is rapid and luxuriant. In good deep loams lucern is the most profitable of all green crops; when properly managed, the quantity of cattle which can be kept in good condition on an acre of lucern, during the whole season, exceeds belief. It is no sooner mown than it pushes out fresh shoots, and wonderful as the growth of clover sometimes is in a field which has been lately mown, that of lucern is far more rapid. Where a few tufts of lucern happen to be, they will rise a foot above the surface, while the grass and clover, which were mown at the same time, are only a very few inches high.

Lucern, sown in a soil suited to it, will last for many years, shooting its roots downwards for nourishment till they are altogether out of the reach of drought. In the driest and most sultry weather, when every blade of grass droops for want of moisture, lucern holds up its stem, fresh and green as in a genial spring. The only enemies of this plant are a wet subsoil and a foul surface. The first is often incurable; the latter can be avoided by good cultivation.

It is useless to sow lucern on very poor sands or gravel, or on wet clays. The best and deepest loam must be chosen, rather light than heavy, but with a good portion of vegetable earth equally dispersed through it. If the ground has been trenched, so much the better; and if the surface is covered with some inferior earth from the subsoil, it will be no detriment to the crop, for it will prevent grass and weeds from springing up, and save much weeding. The lucern will soon strike down below it. It is not a bad practice to cover the lucern-field with a coat of coal-ashes or poor sand, merely to keep down the weeds, where this can easily be done.

The soil in which it is intended to sow lucern-seed should be well prepared. It should be highly manured for the two or three preceding crops, and deeply ploughed if not trenched. It should be perfectly clean, and for this purpose two successive crops of turnips are most effectual. The turnips should be fed off with sheep. In the month of March, the land having been ploughed flat and well harrowed, a very small quantity of barley, not above a bushel to the acre, may be sown, or rather drilled on the ground, and at the same time from 30 to 40 lbs. of lucern-seed sown broad-cast, and both harrowed in and lightly rolled. If the land will not bear to be laid flat without water-furrows, it will be useless to sow lucern in it.

As the crop comes up it must be carefully weeded; no expense must be spared to do this effectually, for success depends upon it. When the barley is reaped, the stubble, which will probably be strong, should be pulled up by the hand-hoe, or by harrowing, if the plants of lucern be strong, and, at all events, the ground must be cleared of weeds. It must not be fed off with sheep; they would bite too near the crown. Lucern should always be cut as soon as the flower is formed. If it is kept clear of weeds the first year, there will be little difficulty with it afterwards, when the roots have become strong. The second year the lucern will be fit to cut very early, and in a favourable season it may be cut four or five times. After each cutting it is useful to draw heavy harrows over the land, or an instrument made on purpose resembling harrows, the teeth of which are flat, and cut the soil like small coulter. It will not injure the plants, even if it divide the crown of the root, but it will destroy grass and weeds. Liquid manure, which consists of the urine of cattle and drainings of dunghills, is often spread over the lucern immediately after it has been mown, and much invigorates the next growth; but if the land is rich to a good depth, this is scarcely necessary. The lucern will grow and thrive from seven to twelve years, when it will begin to wear out, and, in spite of weeding, the grass will get the upper hand of it. It should then be ploughed up, all the roots carefully collected and laid in a heap with dung and lime to rot, and a course of regular tillage should succeed. The same land should not be sown with lucern again in less than ten or twelve years, after a regular course of cropping and manuring.

Cattle thrive upon lucern. Horses also work well upon it. Cows give plenty of good milk when fed with it. In spring it is apt to purge cattle, which, with a little attention, is not unhealthy for them. If it is given to them in too great quantities, or moist with dew, they run the risk of being hoven. These inconveniences are avoided by giving it sparingly at first, and always keeping it twenty-four hours after it is cut, during which time it undergoes an incipient fermentation, and the juice is partially evaporated; instead of being less nutritive in this state, it is rather more so.

An acre of good lucern will keep four or five horses from May to October, when cut just as the flower opens. If it should get too forward, and there be more than the horses can consume, it should be made into hay; but this is not the most profitable way of using it, and the plant, being very succulent, takes a long time in drying. The rain also is very injurious to it in a half-dry state; for the stem is readily soaked with moisture, which is slow in evaporating. The produce in hay, when well made, is very considerable, being often double the weight of a good crop of clover hay.

Many authors recommend drilling the seed of lucern in wide rows, and hoeing the intervals after each cutting. This is the best way with a small patch in a garden, and when only a little is cut every day; but in a field of some extent, the lucern, when once well established and preserved free from weeds by hand-weeding the first year, will keep all weeds down afterwards, and the heavy harrows with sharp tines, used immediately after mowing, will pull up all the grass which may spring up. No farmer ought to neglect having a few acres in lucern on his best land.

LUCERNAL MICROSCOPE. [MICROSCOPE.]

LU'CIDA, a name formerly given to the brightest star in any constellation: thus we have Lucida Hydræ, Lucida Lyre, &c.

LUMBAGO. [RHEUMATISM.]

LUNACY. Unsoundness of mind is perhaps the most accurate definition of the present legal meaning of this term that can be given. Formerly a distinction was made between lunatics and idiots: a lunatic being described as one who has had understanding, but from some cause has lost the use of his reason; an idiot, as one who has had no understanding from his nativity. The distinction between these two classes of persons of unsound mind also produced some important differences in the management of their property. These have now fallen into disuse, and therefore it will be sufficient for the purposes of this article to consider the consequences to the individual of unsoundness of mind generally. Strictly speaking, perhaps a lunatic is one

who has lucid intervals, but this distinction may also at the present day be disregarded.

Persons of unsound mind may inherit or succeed to land or personal property either by representation, devise, or bequest, but they cannot be executors or administrators, or make a will, or bind themselves by contract. It is stated by Blackstone that the conveyances and purchases of persons of unsound mind are voidable, but not actually void; this however perhaps needs some qualification, for a bargain and sale, or surrender, &c., and also personal contracts made or entered into by such persons, are actually void as against their heirs or other representatives, though it is true a feoffment with livery of seisin was voidable only. [CONVEYANCES.] A person of unsound mind, though he afterwards be restored to reason, is not permitted to allege his own insanity in order to avoid his own act; for no man is allowed to stultify himself, or plead his own disability (13 Vesey, 590), unless he has been imposed upon in consequence of his mental incapacity (2 Carr. & P. 178; 3 Carr. & P. 1, 30); and an action will lie against a lunatic upon his contract for necessities suitable to his station. The reader is referred for information upon this subject to 1 Blackst. *Comm.*, p. 297, Mr. Kerr's ed.; 1 Fonbl. *Eq.*, b. 1, c. 2; Sugd. *Pow.*, 295-6; 5 Barn. & C. 170; Moody & M. 105-6. Acts done during a lucid interval are valid, but the burden of proving that at the time when the act was done the party was sane and conscious of his proceedings, lies upon the person asserting this fact. The marriage of a person of unsound mind, except it be solemnised during a lucid interval, is void.

The degree of responsibility under which persons of unsound mind are placed with respect to crimes committed by them, as well as the degree of unsoundness of mind which should be considered as depriving the party of that amount of self-control which constitutes him a responsible agent, are in a painful state of uncertainty. As a general rule it may however be laid down that where unsoundness of mind, of such a nature as to render the party incompetent to exercise any self-control, is established, criminal punishment will not be inflicted; but that he will be kept in safe custody during the pleasure of the crown (39 & 40 Geo. III., c. 94, and 1 & 2 Vict., c. 14). On the subject of criminal responsibility, and what constitutes unsoundness of mind in a legal point of view, the reader is referred to the various treatises on medical jurisprudence. The following remarks may however be useful.

In lunacy the question to be decided is not whether the individual be actually of sound mind, though a jury on an inquisition held under a commission of lunacy must express their opinion or finding in the form that the alleged lunatic is of "unsound mind" (*In re Holmes*, 1 Russell, 182); but though such must be the finding in order to make a man legally a lunatic, the real question is whether or not the departure from the state of sanity be of such a nature as to justify the confinement of the individual, or the imposition of restraint upon him as regards the disposal of his property. No general rule can be laid down by which to ensure a right decision: but in all such inquiries it should be kept in mind that insanity varies infinitely in its forms and degrees. It should be particularly remembered that persons may be of weak mind, and eccentric, and even be the subjects of delusions on certain subjects, and yet both inoffensive and capable of directing pecuniary matters. The individual's natural character should be taken into consideration as accounting for eccentricities of manner and temper, and his education in estimating his ignorance and apparent want of intellect; and lastly due allowance must be made for the irritation and excitement produced in a mind, perhaps naturally weak, by the inquiry itself, and the attempt to deprive him of his liberty and property. Confidence should not be placed in depositions or evidence founded on short and inattentive examinations.

Sometimes the madman conceals his disease, and with such remarkable cunning and dissimulation that the detection of it is very difficult: this is more particularly the case when the insanity consists in some hallucination; and here, unless the nature of the delusion be known, it will often be in vain to attempt to elucidate by questions any proof of unsoundness of mind. Those who are insane on particular subjects will reason correctly on ordinary and trivial points, provided these do not become associated with the prevailing notions which constitute their disease.

When insanity is urged as the ground of non-responsibility for a criminal act, it has been erroneously held that the main point to be ascertained is, whether the individual has or had "a sense of good and evil," "of right and wrong." But this, though the doctrine of the English law, is found incapable of practical application; and the records of trials of this kind show that the guide to the decision has generally been the proof, or absence of proof, that insanity of some kind existed at the time of the act, although before and after it the power of reasoning and the knowledge of right and wrong might be retained. Thus, on the trial of Hatfield for shooting at George III., Erskine argued that the existence of a delusion in the mind absolves from criminal responsibility, if it be shown that the delusion and criminal act were connected; and on this principle Hatfield was acquitted, but confined for life. Bellingham, however, who shot Mr. Perceval under an equally powerful delusion, in consequence of the greater excitement in the public mind occasioned by the result of the insane act, was convicted and executed. In many instances homicide

has been prompted, not by any insane hallucination or delusion, but by a morbid impulse to kill. Here there is generally evidence of the feelings and propensities of the individual having been previously disordered; of his being, in fact, the subject of moral insanity [INSANITY], and judgment in such cases is aided by the absence of motive to the act.

A lunatic is, according to law, responsible for acts committed during "lucid intervals," a term by which is understood, however, not mere remissions of the violence of the disease, but periods during which the mind resumes its perfectly sane conditions. In forming an opinion concerning such lucid intervals, it is to be remembered that the absence of the signs of insanity must have considerable duration before it can be thence concluded that the mind is perfectly sane; and that lunatics, when apparently convalescent, are subject to sudden and violent paroxysms.

One of the most difficult points to be determined is with regard to the mental capacity of old persons, in whom the mind is confessedly impaired. The decay of intellect in old age is first manifested in the loss of memory of persons, things, and dates, and particularly with respect to recent impressions. But it is not the mere liability to forget names, &c., which will render the will of an old person invalid; it should be shown that in conversation about his affairs, and his friends and relations, he did not evince sufficient knowledge of both to dispose of the former with sound and untrammelled judgment. Many old men appear stupid and forgetful, but when their attention is fairly fixed on their property, business, and family affairs, they understand them perfectly, and display sagacity in their remarks.

The care and custody of idiots and lunatics form a branch of the royal prerogative, and were formerly administered by the king himself. Since the dissolution of the Court of Wards, the lord chancellor has been specially appointed to exercise this power. [CHANCELLOR.] The method of proving a person to be of unsound mind, for the purpose of depriving him of the control of his property, and, where the circumstances require it, providing for the safe custody of his person, was formerly as follows. The lord chancellor, upon petition supported by affidavits, and in some cases upon a personal interview also with the alleged lunatic, when such a course seemed necessary, granted a commission to inquire into the state of mind of the party, and if the jury found him to be *lunatic*, or of *unsound mind* (one of which modes of finding was absolutely necessary), the care of his person was committed to some relation or other fit person with a suitable allowance for maintenance, who was called the committee of the person; and the care of the estate was committed either to the same or some other person, who was called the committee of the estate. [GUARDIAN.] The committee of the estate was considered as a mere bailiff appointed by the crown for the sole interest of the owner, and without any regard to his successors; but the court might order allowances to be made to near relations of the party of unsound mind, and even to his natural child, where the circumstances of the several parties justified and required it, and would direct proper acts to be done in the management of the estate, as repair of buildings, felling of timber which was deteriorating, &c.

The procedure at present is essentially the same as formerly, but much legislation has recently taken place on the subject, and now the Act 16 & 17 Vict. c. 70, styled the Lunacy Regulation Act, 1853, has consolidated most of the laws and provisions previously in force. Under this Act the lord chancellor may appoint two serjeants or barristers-at-law, to be called masters in lunacy, who are to have and execute all the powers, duties, and authorities formerly had and executed by commissioners named in commissions in the nature of writs *De Lunatico Inquirendo*. The masters conduct their proceedings either separately or together under the orders and direction of the chancellor.

The chancellor also appoints three visitors, two medical and one legal, whose function it is to visit and report upon the condition of every lunatic of whom the court has the care.

The lords justices of the Court of Appeal in Chancery may also, by virtue of the Queen's sign manual, be entrusted with the care of lunatics, and have the same jurisdiction as the lord chancellor.

The term *lunatic* is only properly applied to a person who is found to be a lunatic by the verdict of a jury under an inquisition. But the term *lunatic* is also applied to those who, being considered lunatics, are confined in lunatic asylums or hospitals without having been found lunatics by inquisition.

The subject of insanity and asylums for the insane has of late years occupied a very large share of public attention; particularly as an opinion has prevailed that insanity is on the increase in this kingdom beyond the ratio of population. The want of accurate information renders this point doubtful; but it is certain that more than 20,000 insane persons are in confinement in the public asylums and licensed houses in England and Wales, of whom 16,000 are paupers. But as a great number of patients are confined separately, or in the care of their relatives, of whom no public returns are made, this number is probably far below that of the persons insane in the country.

Recent legislation has placed the powers vested in the commissioners in lunacy on an entirely new footing, and has in many respects modified the constitution of asylums. The Act 8 & 9 Vict. c. 100, repeals 2 & 3 Wm. IV. c. 107; 3 & 4 Wm. IV. c. 64; 5 & 6 Wm. IV.

c. 22; 1 & 2 Vict. c. 73; 5 Vict. c. 4; and 5 & 6 Vict. c. 87. The same Act appoints six commissioners, three of whom are physicians and three barristers, with salaries; and five other commissioners who act gratuitously. No person can act as a commissioner who within one year has been directly or indirectly connected with any asylum. Licences are granted by these commissioners at each of their quarterly meetings. Any person who wishes to open a house for the reception of patients is required to send a plan upon a scale of one-eighth of an inch to a foot of every part of the premises at least fourteen days previous to his application. No additions to or alterations in a licensed house can be made without the consent of the commissioners. No licence is to remain in force more than thirteen months, and the notice of a wish to renew must give the number of patients then confined. The jurisdiction of the commissioners extends to the whole of London and Middlesex, and Southwark; and to all places within seven miles of London, Westminster, and Southwark: in the country the licences are to be granted by the justices of the peace in quarter-sessions, who are bound to appoint three of their number, together with one physician, surgeon, or apothecary, as visitors of the asylums licensed by them. Strict regulations are enforced for the reception of patients; it is required that every person, not being a pauper, received as insane, shall be certified to be so by two physicians or surgeons, who shall visit such patient separately, and shall have no interest in the asylum in which such patient is to be confined; and certain entries of these particulars are to be kept at each asylum. For a pauper, the certificate of one medical man and the order of two justices is required.

Penalties are fixed for neglecting these rules, or those which direct notice to be given of every admission, death, discharge, or escape. Houses having 100 or more patients are to have a resident medical attendant, and those of smaller size are to be visited by a medical attendant at defined periods, according to their size. Every house within the immediate jurisdiction of the commissioners must be visited by them at least four times in the year, and every other house at least twice in the year; these visits may be made at any hour, even by night, and it is penal to conceal any part of a house from them. Similar powers are given to the visitors in the country.

The commissioners present an annual report to the lord chancellor of the state of the different asylums visited by them, which report is laid before parliament.

An important alteration is made in the law concerning the care of single patients. Orders and medical certificates must now be procured for the care of one patient, similar to those used for the admission of patients into licensed houses; and copies of these documents are to be privately sent to and registered by the secretary to the commissioners. This Act only extends to England and Wales, and is amended by 16 & 17 Vict. c. 96, and 18 & 19 Vict. c. 105.

The Act 16 & 17 Vict. c. 97, relates to the regulation of lunatic asylums for counties and boroughs, and the maintenance and care of pauper lunatics; and gives to the commissioners a great power over these institutions, which had formerly been entirely under the control of justices of the peace. The justices of every county and borough are now compelled to erect or to join in the erection of an asylum, where none such already exists. This Act only extends to England and Wales.

The patients who are confined in prisons, hospitals, workhouses, or in the houses of their relatives, are exposed perhaps more than any others to great neglect and mismanagement, and not unfrequently are treated with great cruelty, even when the intentions of the parties who have charge of them are good, through their entire ignorance of the nature and proper treatment of the disorder.

As to the persons and property of such so-called lunatics who have not been found lunatic by a jury, the 8 & 9 Vict. c. 100, § 94, enacts, That whenever the commissioners in lunacy shall have reason to suppose that the property of any person detained or taken charge of as a lunatic is not duly protected, or that the income thereof is not duly applied for his maintenance, such commissioners shall make such inquiries relative thereto as they shall think proper, and report them to the lord chancellor. Sect. 98 enacts, That when any person shall have been received or taken charge of as a lunatic upon an order and certificate under the provisions of that Act, and shall either have been detained as a lunatic for the twelve months then last past, or shall have been the subject of a report by the commissioners in lunacy in pursuance of § 94, the lord chancellor shall direct one of the masters in lunacy to inquire and report to him as to the lunacy of such person so confined; and the chancellor is authorised to make orders for the appointment of a guardian or otherwise for the protection, care, and management of such lunatic, and such guardian is to share the same powers and authorities as a committee of the person of a lunatic found such by inquisition has, and to appoint a receiver or otherwise for the care and management of the estate of such lunatic; and such receiver is to have the same powers as a receiver of the estate of a lunatic found such by inquisition has; and the chancellor is also empowered to make orders for the application of the income of the lunatic towards his maintenance, and the cost of the care and management of his person and estate, and also as to the investment or other application for the purpose of accumulation of the overplus; but such protection, care, and management are only to continue so long as such lunatic shall continue to be detained as a lunatic upon such order or certificate as

aforesaid, and such further time, not exceeding six months, as the chancellor may fix; but the chancellor may in any such case, either before or after directing such inquiry, and whether the master shall have made such inquiry or not, direct a commission in the nature of a writ *de lunatico inquirendo* to issue, to inquire of the lunacy of such person.

In the Roman system, persons of unsound mind (*furiosi*) might be deprived of the management of their property on application to the prætor by their next of kin. This legislation was either introduced or established by the Twelve Tables. The person who had the care of the lunatic and of his property was called a curator. [CURATOR.] The Twelve Tables gave the care of the lunatic to his agnati. In those cases where the law had not provided for the appointment of a curator, the prætor named one. ('Dig.' 27, tit. 10; 'Instit.' 1, tit. 23.)

The law with respect to lunatics in Scotland is consolidated by the statute 20 & 21 Vict. c. 71, as amended by the 21 & 22 Vict. c. 89.

The Act 5 & 6 Vict. c. 123, continued by 18 & 19 Vict. c. 76, provides for private lunatic asylums in Ireland. The Acts 1 & 2 Geo. IV. c. 33; 9 & 10 Vict. c. 115; and 18 & 19 Vict. c. 109, regulate the asylums for the lunatic poor in Ireland.

LUNAR CAUSTIC. [SILVER, NITRATE OF.]

LUNAR ECLIPSE. The phenomenon of a lunar eclipse is occasioned by the passage of the moon through the earth's shadow, and the consequent interception of a portion of the solar light which usually falls upon the moon's surface. In the annexed figure, let A B

represent a section of the sun drawn through a great circle on its surface, and C D a similar section of the earth's surface, both sections being supposed to be in the same plane. Let the common tangents to these sections, A X, B Y, A M, B N, be drawn. In consequence of the great distance of the sun these tangents may be supposed to intersect each other at A, B and C, D, the opposite extremities of two parallel diameters. It is plain that the space C D Z is a section of a cone, and that within its limits there will be a total interception of the sun's light. Hence, when the moon in the course of her monthly revolution passes into this cone, she will undergo an eclipse, which will be total or partial, according as she plunges wholly or partially into the terrestrial shadow. Within the region enclosing the shadow represented by X C Z, Z D X, there will be a partial interception of the solar light. This region is termed the penumbra. If the moon revolved in the plane of the ecliptic, she would pass through the terrestrial shadow every time that the earth was interposed between her and the sun, and consequently she would undergo an eclipse in the course of each monthly revolution; but, in point of fact, the lunar orbit is inclined to the plane of the ecliptic at a mean angle of somewhat more than 5°. It happens, from this circumstance, that an eclipse of the moon can occur only when the moon is near either of the nodes of her orbit. It is found, by calculation, that if the distance of the node from the point of the ecliptic opposite to the sun should exceed 11° 25' 40", there will be no eclipse. On the other hand, if the distance of the node from the same point should fall short of 9° 20' 29", there must be an eclipse. Within these limits there may or may not be an eclipse, the question of the occurrence of such a phenomenon depending on the relative distances of the sun and moon from the earth at the time of opposition.
